EARTHQUAKE, a shaking of the solid ground by more or less violent movements, produced by natural forces. Such shakings, to which every part of the world is liable, are often imperceptible except to very sensitive instruments, but on the other hand are frequently productive of fearful destruction of life and property. These phenomena claim our special attention, since we must hope through them to make our next steps toward a full knowledge of the condition of the interior of our globe. After briefly considering the history of our knowledge of this subject as shown in its bibliography, we shall recount successively a few of the remarkable earthquakes, and shall then proceed to a short summary of our present knowledge of the subject, giving first some general views on the distribution of earthquakes, and then reviewing some of the many theories that have been broached in connection with this subject; in conclusion we shall give with some minuteness the remarkable results attained by Mallet and others who have lately established the science of seismology (Gr. *σεισμός*, earthquake) upon a firm basis.—Among the classical writers, Aristotle, Strabo, Seneca, Pliny, Josephus, &c., give numerous facts mixed with fanciful theories on the subject of earthquakes. In the earlier works of the modern revival of knowledge, Beccaria, Bylandt, Flamsteed, Percival, Priestley, Stukely, and others, have sought with but little success by observations and theories to advance our knowledge of the origin of earthquakes; and with these we may class the memoir by Michell published in 1760. Of the works belonging to the present age of philosophical inquiry may be mentioned, first, those that treat specially of the phenomena of individual earthquakes, such as Kant, Roche, and Pereira, on the Lisbon earthquake of 1755; the report to the academy of Naples on the great earthquake of 1783 in Calabria; that of Palmieri and Scacchi on the Melfi earthquake of 1851; that of Volger on the earthquake of Viège, 1855; the report by Gilliss on his astronomical expedition to Chili, 1849-'52; and that of Mr. Mallet to the royal society at Lon-

don on the Neapolitan earthquake of 1857, which was published in 1862 under the title of "First Principles of Observational Seismology." Numerous special or general catalogues of earthquakes have been published, of which we note those of Von Hoff, Cotte, Hoffmann, Merian, and especially the great catalogue of Mallet, "The Earthquake Catalogue of the British Association," which very complete record embraces between 6,000 and 7,000 earthquakes recorded between the years 1606 B. C. and A. D. 1842. For the interval 1842 to 1872 the catalogues compiled by Perrey and published from time to time in the transactions of the Belgian royal academy form an almost exhaustive record. The special catalogues of Perrey for southern Europe, of W. T. Brigham for the United States, &c., may also be consulted. The catalogue by Scrope in his treatise on volcanoes (2d ed., revised and enlarged, 1872) is quite trustworthy for the most recent dates. Of theoretical works on the nature and origin of earthquakes there is scarcely any end, but among the few who have really advanced this branch of knowledge we may mention Dr. Thomas Young and Gay-Lussac, who seem to have remarked the similarity between earthquake shocks and the vibrations of sounding bodies, and Mr. Mallet, who, viewing all the phenomena with the eye of an expert mechanical engineer and by the application of rigidly exact measurements and inductive reasoning, has undoubtedly succeeded to a remarkable degree in perfecting our views of the forces acting during an earthquake, and advanced our knowledge of the ultimate origin of the initial disturbance. The intimate connection between the phenomena of geology on the one hand and of volcanoes and earthquakes on the other has been treated of with more or less fulness by Babbage, Élie de Beaumont, Leopold von Buch, Dana, Darwin, Daubeny, Forbes, Herschel, Hopkins, Höttingen, Humboldt, Hunt, Lyell, Murchison, Phillips, Ritter, Rogers, and Scrope; and the established laws of dynamics, of heat and of strength of materials, have been applied with much success to the question of the origin of these disturbances by Houghton, Hopkins, Oldham, Prévost, Thomson, and especially by Mallet (see his preface to Palmieri's "Vesuvius," London, 1873). Of general treatises, that by Prof. J. D. Whitney, "Earthquakes, Volcanoes, and Mountain Building" (New York, 1871), and that by Prof. Boccardo, *Seismopirologia* (Genoa, 1869), are among the most recent. The essay by Mallet lately presented to the royal society promises when printed in full to mark an epoch in the science of seismology. Interesting matter will also be found presented in a popular style in Reclus on "The Earth."—*Memorable Earthquakes*. In southern Italy and Sicily no century has elapsed since the earliest periods of history that has not been distinguished by severe if not frequent earthquakes. From 1773 to the end of 1776 this region was almost

constantly disturbed; no fewer than 947 shocks were experienced in the first of these years, of which 501 were of the first degree of force. Lyell observes that great importance attaches to these from the minuteness of the observations of men competent to collect and describe with accuracy the physical facts that throw light on geological questions. The great earthquake of 1783 in Calabria probably caused the death of 100,000 persons, and was felt in a great part of Europe; it was fully described by the commission of the Neapolitan academy. The origin of the shock was at a spot under the centre of Calabria; the disturbance passed under the sea without producing any great sea wave, but on reaching the opposite coast of Sicily destroyed the city of Messina. The destructive sea wave that entered the harbor of the latter city was not propagated across the sea, but was probably caused by the dislocation of large masses of rock that fell into the waters near Messina. In central Italy, among the earliest of the recorded earthquakes is that of the year A. D. 63, which resulted in the partial destruction of Herculaneum and Pompeii, 16 years previous to the time when those cities were buried under the lava and ashes accompanying an eruption of Vesuvius. The earthquake of 1857 in the kingdom of Naples is the most noteworthy that has occurred there during the present century, not only because of its extent and fatal violence, but even more so because of the masterly investigation to which its phenomena were submitted by Mallet on behalf of the British association for the advancement of science. This earthquake was felt throughout the kingdom of Naples; in the city itself comparatively slight damage was done, the chief scene of the destruction being in the provinces. The velocity with which the wave of shock spread in all directions from its origin near the town of Potenza was about 775 ft. per second. Of the many suggestive results of Mallet's investigation we shall have occasion to speak further on.—The earthquake of 1855, known as the earthquake of Viège, has been carefully studied by Volger. It was felt slightly in Paris, Mentz, and Geneva; the region of greatest violence was between Bern, Lugano, and Chamouni; the velocity of translation of the wave of shock was northward 2,861 ft. per second, but southward only 1,391 ft. On Nov. 14, 1861, another great earthquake occurred in Switzerland, simultaneously with which it was noticed that in the artesian wells at Passy, Paris, the sediment suddenly increased from 956 to 2,268 grains per cubic metre, after which it began to decrease. In general it has been noted that the springs of this place are similarly affected by almost every earthquake of western Europe.—In Portugal, the city of Lisbon was visited on the morning of Nov. 1, 1755, by one of the most memorable earthquakes recorded in history. The rumbling sound that precedes most earthquakes was immediately followed by the great shock which

threw down the principal portion of the city. The sea retired, leaving the bar dry, and returned in a minute as a great wave or breaker 50 ft. or more in height. It is believed that 60,000 persons perished in the space of six minutes. The part of the city that was permanently engulfed beneath the waters of the bay was covered to the depth of 600 ft. The portion of the earth that was shaken by this earthquake was estimated by Humboldt as equal to four times the extent of Europe; but many of the reports and estimates in reference to it have been greatly exaggerated, and from more exact considerations Reclus states that probably an area equal to six times that of France was sensibly disturbed. The shock was felt in the Alps and on the coast of Sweden; in Bohemia the warm springs of Teplitz disappeared for a time, and again burst forth, deluging the region with ochre-stained waters. Many towns were destroyed in northern Africa. The waves of shock reached Scotland, probably passing under it, causing temporary changes in the waters of Loch Lomond, which suddenly rose more than two feet and then fell to below their usual level. Almost if not quite simultaneously there began the great eruption of the volcano of K  tloggja in Iceland. The velocity of propagation of the wave of shock was about 2,000 ft. per second, and its origin was probably under the ocean some distance west of Portugal. The great sea wave that swept over the coast of Portugal was nearly 60 ft. high at Cadiz, and extended to Madeira, and possibly to the West Indies. The numerous other earthquakes and earthquake waves experienced during the same month throughout Europe and America may very probably have had some connection with that at Lisbon, but are not to be confounded with the shock of Nov. 1.—In Syria, the Biblical records preserve notices of earthquakes in the reign of Ahab, about 900 B. C., and again in the reign of Uzziah, about 800. The earthquake that devastated Judea at the time of the battle of Actium, 31 B. C., was such as according to Josephus had never happened before, and caused the death of 10,000 persons. That which occurred at the crucifixion was accompanied by a darkness very similar to that recorded Jan. 22, 1835, in Central America, on the occasion of the eruption of the volcano Coseguina and the attendant earthquake. The ancient city of Antioch has been peculiarly visited from time immemorial. Besides many other instances, the following may be especially noted: The city was almost destroyed A. D. 115, at the time of the visit of the emperor Trajan, who was himself hurt. In 458 it was again visited, and in 526 occurred the most disastrous one of which any record has been preserved; Gibbon states that 250,000 persons are said to have perished at this time. Sixty years later, in 587, an earthquake destroyed 30,000 persons. The last occurred there in April, 1872.—In India, by the

earthquake of 1819, a tract of 2,000 sq. m. of country near the mouth of the Indus was submerged, and a neighboring region elevated into a mound. The great earthquake of Jan. 10, 1869, has been studied by Oldham with results of great value. The origin of the shock was a point under Asaloo, somewhat deeper down than in the Neapolitan earthquake as investigated by Mallet. Eruptions of sand and hot water took place through the fissures, forming cones. The entire lower valley of the Ganges was embraced in the field of disturbance, and the shock was felt quite decidedly at Calcutta.—In mid ocean there are certain regions frequently visited by earthquakes, if we may rely on the testimony of those navigating them. Among these may be specially designated the portion of the Atlantic ocean near the equator and about half way between Guinea and Brazil.—In the United States, in 1811, occurred the famous earthquake of New Madrid in Missouri, in the valley of the Mississippi river. Humboldt remarks that it presents one of the few examples of the incessant quaking of the ground for several successive months far from any volcano. Over an extent of country stretching for 300 miles southward from the mouth of the Ohio river the ground rose and sank in great undulations, and lakes were formed and were again drained. The surface burst open in fissures that generally trended N. E. and S. W., and were sometimes more than half a mile long; from these fissures mud and water were often thrown as high as the tops of the trees. During the continuance of these convulsions the inhabitants distinguished two classes of movements, the vertical and the horizontal; the latter were regarded as far more desolating than the former. The disturbances continued over what has since been called "the sunk country" until March 26, 1812, when they ceased coincidently with the great earthquake of Car  cas. The most severe earthquake that has been recorded in the middle and eastern states was that of Nov. 18, 1755. The shock then felt in New England was undoubtedly a wave promulgated from either the same centre whence emanated the tremendous disturbance that had destroyed Lisbon on the first day of the month, or from a centre whose activity had been stimulated by the continual quakings that then prevailed from Iceland to the Mediterranean. This earthquake of the 18th began in Massachusetts with a roaring noise like that of thunder; after a minute's continuance of this there came the first severe shock with a swell like that of a long rolling sea—a swell so great that men in the open fields ran to seize something by which to hold on lest they should be thrown down. After two or three lesser shocks there came the most violent of all, producing a quick horizontal tremor with sudden jerks and wrenches; this continued two minutes, and after a slight revival died away. Numerous other shocks followed in the course of a month. In Boston the main shock threw

down or dislocated and twisted many chimneys, wind vanes, brick buildings, &c., and throughout the country it threw down the rude stone walls bounding the farms; new springs of water were opened; the vessels in the harbor felt the shock; large numbers of fish were killed and floated on the surface of the water. Nine hours afterward, at 2 o'clock P. M., a sea wave 20 ft. high, that had undoubtedly originated at the source of this earthquake, arrived at the harbor of St. Martin's in the West Indies. On Oct. 19, 1870, occurred the most considerable shock that has been observed in the middle and eastern states during the present century. The source of this disturbance has been traced with some probability to the volcanic region 50 to 100 m. N. E. of Quebec; from this region the shock spread to St. Johns, New Brunswick, and thence was felt westward to Chicago and southward to New York. The velocity of the wave of shock was about 14,000 ft. per second. The occurrence of the shock felt at Quebec was telegraphed to Montreal by the operators of the Montreal telegraph company in time to call the attention of those at the latter city to the phenomena about 30 seconds before the shock reached them. In California, the earthquake of 1852 destroyed one of the southern missions. That of March 26, 1872, was the most severe that has occurred there during many years; special damage was done in San Francisco by the cracking of the walls of fine public buildings. In Nevada, the mining regions suffered in 1871 by the destruction of Lone Pine and other settlements. In Mexico a disastrous earthquake occurred June 19, 1858. It extended throughout the valley of Mexico, demolishing the aqueduct that supplies the city with water; it was felt in most of the surrounding provinces, where it also did great damage, and was in some places recorded as being the most severe ever experienced there.—In the West Indies, subject as they are to very frequent shocks, we need only note that of June 7, 1692, by which Port Royal, the capital of Jamaica, was in less than three minutes sunk beneath the sea. The fissures produced in the earth opened and closed so rapidly that in some cases, it is said, the lower parts of the bodies of persons were buried while the upper portions remained above ground.—In San Salvador, near the capital, is a volcano that was thrown up in 1770, and which is very similar to Stromboli in the regularity of its intermittent eruptions; it has remained in a state of constant activity, and continues to increase in size by means of the accumulation of ejected lava, ashes, &c. Its origin was preceded by earthquakes for several months, and on Feb. 23, 1770, by the opening of a crevice whence issued lava, ashes, smoke, and flame. On March 19, 1873, San Salvador was utterly destroyed. Three successive severe shocks were experienced; but the inhabitants were by the previous noises so well warned that a comparatively small loss of life (less than

500) took place. The frequency of earthquakes in this region is expressively told by the name given to it by the aboriginal Indians, Cuscatlan, "the land that swings like a hammock."—In South America, the city of Carácas, Venezuela, was entirely destroyed by three shocks within 50 seconds on March 26, 1812. In Ecuador, the city of Quito was almost destroyed on March 22, 1859. On Aug. 16, 1868, a terrible earthquake devastated a large part of Ecuador; this was one feature in the series of severe shocks that between the 13th and 16th were experienced over nearly the whole of the southern half of the eastern coast of the Pacific ocean. In Peru, Callao was destroyed in 1586; the accompanying sea wave must have been about 90 ft. high, and resulted from the joint action of two shocks. It was again destroyed in 1746. On Aug. 13 and 14, 1868, the seaport of Arica suffered severely; and during several days there occurred numerous shocks throughout the coast region from lat. 10° to 25° S. The earthquake sea wave was specially destructive (see ARICA), and it sped thence across the Pacific ocean, reaching the Hawaiian islands on the 14th and Yokohama on the 15th; it was also felt on the coasts of Australia and of Alaska. Among the numerous earthquakes that have visited Chili we will mention three very instructive ones. That of 1822 is interesting historically, because the accounts given of certain twisting effects led Mallet to enter upon those dynamical studies that have done so much to elucidate the obscure points in seismology. The earthquake was itself a very severe one, and specially interesting, since in connection with it there occurred a permanent elevation to the extent of from two to seven feet of fully 100,000 square miles of land lying between the Andes and the coast; lines of sea beaches at higher levels and further inland indicate the previous lifting up of the same region at different times along the same lines. About midnight of Feb. 20, 1835, the city of Concepcion was for the fourth time destroyed; there were felt over 300 successive shocks within two weeks; the accompanying sea wave was 30 ft. high, and probably originated near the island of Juan Fernandez, where there also simultaneously broke forth a submarine volcano, which sent up a column of fiery ejecta through a depth of 400 ft. of water; about the city of Concepcion the sea water was black and of an offensive smell, killing many fish. Among the numerous earthquakes observed by Gilliss during his astronomical expedition to Santiago was that of April 2, 1851, the most severe since 1822. The heaviest portion continued a minute and a half, within which interval were experienced continuous rumbling and innumerable severe shocks or oscillations. The movements of pendulums and other free bodies were nearly in the meridian. The warning rumbling noises preceded the shock by about 15 seconds. The earthquake was severely felt over a region extending 200 m. N. and

S., and at least 100 m. E. and W.; the point of greatest severity was apparently 30 m. S. of Santiago, though at all places visited by it it seemed to come from some point further south. This earthquake was one of the cases, extremely rare in Chili, in which the origin of the disturbance was under the mainland, and where therefore no great sea wave was produced. In the Argentine Republic, Mendoza was overturned in March, 1861; the shock was very severe, and continued from the 20th to the 23d over Buenos Ayres and the entire confederacy, and 12,000 persons are estimated to have perished.—In the Hawaiian islands, the most severe earthquake ever known occurred on Feb. 19, 1871. At Honolulu it lasted 50 or 60 seconds, the motion being chiefly vertical with a N. E. and S. W. rocking movement; a roaring sound that was also heard far out at sea preceded the shock, and it was noticed that vessels that lay furthest from the wharves were first struck, and afterward those close to the shore. At Lahaina the direction of the vibration was S. and N. On the W. coast of Hawaii the shock was as severe as on the S. coast of Oahu; it seemed to come from the west. The various observed phenomena point to a centre of disturbance near the centre of the circle in the circumference of which is the group of islands.—In the East Indies is a seat of almost perpetual volcanic and earthquake activity. In 1772, during an eruption of Papandayang, one of the loftiest volcanoes of Java, an area of 100 sq. m. was overwhelmed with ashes (not submerged under the sea), destroying about 40 villages and 3,000 inhabitants. Simultaneously eruptions took place from two volcanoes respectively distant 184 and 352 m. from Papandayang, although the many neighboring volcanic vents were quiet. On July 3, 1863, the city of Manila was much damaged by a violent earthquake; two systems of shocks were experienced, trending respectively in a N. to S. and E. to W. direction. The islands of Japan are subject to numerous violent disturbances. The earthquake of Dec. 23, 1854, which destroyed the ports of Simoda and Osaka and injured the city of Yedo, was accompanied by a sea wave 30 ft. high, which made the destruction more complete, and then swept eastward over the Pacific ocean in a series of five or seven waves that were felt a few hours later at the Bonin islands and on the California coast, affording Bache an opportunity to determine approximately the average depth of the water.—*Registration of Earthquakes.* The observations of the nature of earthquake shocks have heretofore been generally indefinite and unsatisfactory. Every disturbed stone or other object forms of itself a permanent record of the force and direction of the shock, but the difficulty of properly interpreting the often complex results has led to the suggestion of a system of automatic registration by means of permanent simple instruments called seismographs, of which the following

are some of the principal: 1. Horizontal plates of glass, wood, or stone, strewn with sand or loose blocks of various sizes, densities, and proportions, show by the changes impressed on the positions of the movable materials the direction and force of the horizontal components of a shock. 2. Tide gauges record not only the great sea wave, but also the smaller forced waves that precede this, and therefore give the means of determining the time of the occurrence as well as other data. 3. Similarly, the self-recording mercurial barometer, if sufficiently sensitive, records the time and also the force of the vertical component of the shock. 4. The delicate levels of the accurate astronomical instruments give information of the slightest change of level, and have in the hands of Wagner recorded vibrations that would otherwise have wholly escaped the senses. 5. An accidental observation of Gilliss, who happened to be viewing the moon during a slight earthquake, shows that by means of a telescope sighted on celestial or distant terrestrial objects we may become aware of the slightest imaginable vibrations, which may be recorded photographically. 6. The telegraph as used by Gilliss at Santiago in 1852, and by the operators in Montreal in 1871, may be used especially with a chronograph to record the times of transit of a shock as it passes several stations successively. 7. The self-recording magnetometers afford a very delicate record of the changes affecting the suspended needle, and also of the effect of the shock on the magnetic condition of the globe. 8. Pendulous bodies (neither barometers nor magnetometers, but simple pendulums) have long offered a favorite mode of observing the direction of the shock, which is the same as the azimuth of the axis of the ellipse described by the pendulum in consequence of the disturbance; the force of the shock is recorded by the extent of the arc of vibration. 9. Vertical spiral springs, from which weights are suspended or upon which they press, afford very delicate means of observing and recording the vertical component of the force. 10. The Cacciato seismometer consists simply of a basin filled to the brim with mercury; at the eight points of the compass are small holes through which the liquid may be projected by the force of the earthquake shock. 11. Lamont's apparatus consists of finely balanced needles, to which may be attached small mirrors throwing a reflected beam of light into a telescope, so that the slightest movement may become visible. 12. The most complete instruments for self-registration are those employed by Palmieri, Kreil, and Mallet, but the last is far more perfect than any other. Palmieri's apparatus consists of a fillet of paper drawn along uniformly, on which are made marks corresponding to the times and extent of the disturbances communicated by the vertical component of the shock to certain weights hung on spiral springs; for

the horizontal component Palmieri employs four open U-shaped tubes partly filled with mercury; they are so set up that the planes of the tubes are directed toward different points of the compass; when the earthquake shock disturbs the quiescent mercury, a galvanic current is made or broken, by which the time record is made on a moving fillet of paper; light floats are also disturbed, and show by the extent of their movements the force of the shock. 13. The preceding instrument has some points of resemblance with that first proposed in 1846 by Mallet; the latter is however calculated to resolve with greater ease and accuracy all the problems connected with terrestrial waves of shock. Mallet employs one vertical and four horizontal L-shaped glass tubes, each separated from the other and filled for a short distance with mercury; the mercury being originally in a quiescent state, the linear motion that is communicated to it relative to the sides of the tubes by the wave of shock breaks or makes a galvanic circuit by which the time is recorded on a revolving cylinder; the extent of the vibrations of the mercurial column is also recorded by appropriate dots or lines, and the apparatus is so placed that we are able to deduce the movements of the earth in three directions, vertically, meridionally, and at right angles thereto, whence the angle of emergence and all the other local phenomena may be calculated. 14. Kreil of Vienna proposed in 1855 to employ a pendulum suspended by two independent springs, of which the lower for instance allowed of motion in the meridian, but the upper in a plane at right angles thereto; the movement of the pendulum is recorded by its lower end marking on a revolving disk of paper or metal.—*Connection between Earthquakes and Volcanoes.* The intimate relation of these phenomena is apparent at once to even the most careless observer, but correct and exact ideas on the subject have been attained only within the present age. On the one hand, earthquakes are most numerous in the volcanic regions of the globe; on the other, they are not at all confined to these centres; they are sometimes attended by the growth or formation of volcanoes, and in general no volcanic activity is manifested without being attended by more or less notable earthquakes, the quakings being however to a great degree confined to the volcano in eruption; the only exception to the latter statement can indeed be shown to be explicable in such a way as to give further confirmation of the general statement that the strains, pressures, and explosions occurring within the depths of the solid earth give rise at the surface of the globe, if feeble, to slight earthquakes, and if stronger, to more severe shocks accompanied by upheavals and depressions; if yet stronger, though not paroxysmal, to the formation of fissures, volcanic vents, and eruptions of steam, gases, hot water, mud, scorïe, ashes, lava, and flying stones. A slight earthquake central in

a non-volcanic region is "an uncompleted effort to establish a volcano." The presence of a volcano is demonstrative of a previous earthquake, and the volcanic vent, offering as it does a way of easy escape for gases, &c., is, unless it becomes clogged up, to some extent an assurance that subsequent earthquakes in its immediate region will be of less severity. The area thus protected may extend to a distance of 100 miles from the volcano, but is usually much less, showing that within the earth's surface the centres of the origin of earthquake disturbances are often quite insulated. The exceedingly great variety in the strata of the earth and the nature of the volcanic eruptions necessitates a special study of the individual cases, in order to perceive how intimately and yet how diversely these phenomena are associated with every variety of earthquake.—*Atmospheric Relations.* The connection between the atmosphere and the earthquake, though probably incidental, is an important one. It is found that there is a decided increase in the frequency and severity of shocks during the rainy season, at least in certain localities, and especially, as Mallet says ("First Principles of Seismology," 1862), in very dry countries such as Asia Minor and Syria, and in the volcanic regions where eruptions of steam prevail, and where the melted snows and heavy rains are rapidly drained off into deep fissures. There seems to be no reasonable doubt that in these cases the pressure of the drainage water directly affects the liquid in the interior of the earth, and increases the supply of both steam and lava for the volcanoes, as well as the liability to such internal explosions of steam as may originate the earthquake shocks. That the diminution of atmospheric pressure such as prevails over the central regions of some severe storms, or during certain seasons, cannot directly be of importance in comparison with the above mentioned more powerful hydrostatic pressure, seems quite evident; yet there are volcanoes, such as that of Stromboli, where the conditions of equilibrium are so delicately adjusted that, according to the testimony and traditions of those living in their neighborhood, their activity increases perceptibly on the approach of every storm.—*Geographical Distribution of Earthquakes.* Besides the preceding general relations between earthquakes and volcanoes, it is important to consider the distribution of the former, or rather their segregation in certain well marked regions. It is not necessary in this place to enumerate the regions of volcanic activity, although these are peculiarly also subject to earthquakes. (See VOLCANO.) The regions that are far removed from active volcanoes, yet specially subject to earthquake shocks, are, in the order of the severity of the phenomena, the Himalaya mountains and India, Syria, Algeria, the W. coast of North America, the Mississippi valley, Scotland, New England, and the Saint Lawrence valley. The re-

gions that are at present comparatively free from sensible earthquakes are Egypt and the eastern and southern portions of Africa, northern Europe and Asia, Australia, many portions of North America, the eastern portion of South America, and Greenland.—*Chronological Distribution of Earthquakes.* The contortions of geological strata, their faults and fissures, and still more the presence of old trap dikes, &c., that break through every known geological formation, sufficiently show that in every part of the world earthquake phenomena have been common at some time throughout the entire history of the globe since the formation of its solid crust; indeed, we have in these phenomena the record of the condition of the interior of the earth at successive stages separated by long intervals of time. The periodicity of earthquakes has been studied by many writers, of whom among the earliest was Merian, whose conclusion, confirmed by Mallet, Perrey, Volger, Kluge, Bridgman, &c., was that these occur more frequently in the winter than in the summer months, as for instance in New England, Bridgman finds that between 1638 and 1869, of 227 earthquakes, 148 occurred during the winter half of the year, and 74 during the summer half. If this were an annual period independent of the wet and dry climatological seasons before alluded to, it would be of deep import; but on the contrary it is less marked in some countries than in others, its laws being apparently peculiar to the various centres of shock; it has therefore been treated in the preceding section as one depending on climatological considerations. Mallet has indeed shown that, considering the whole world in one view, there is a preponderance of shocks recorded in certain months; but it is possible, as he states, that this preponderance results from the greater fullness of the records relating to them for the northern hemisphere. A daily period has also been recognized, such that more shocks are recorded during the day than during the night. This periodicity, which has been demonstrated for Switzerland, if it (as thus enunciated) be a law of nature, will be so neutralized by the corresponding daily period of the antipodal regions, that in the total sum of the earthquakes over the whole earth no such period will be noticed. The gradual diminution and ultimate cessation of earthquakes, as maintained in 1771 by Castilhon, and the periods depending on hurricanes and on electric phenomena, are all too poorly established to be worthy of more than a passing mention. Thus also must we dismiss the attempts of Falb and others to predict earthquakes for any considerable period in advance. The other periods of really cosmical importance are as follows: 1. That depending on the variations in the solar spots. 2. That depending on or connected with terrestrial magnetism. These two classes of phenomena, however, have as yet not been so well established as is necessary to their full acceptance. Lamont (1840), Varley (1870),

and Sumichrast (1871) trace a connection between terrestrial magnetism and earthquakes, though they differ as to whether the former is to be considered as the cause or the consequence of the latter; most likely is it that both are consequences of a deeper common cause; in either case, however, there results a periodicity of earthquakes allied to the known periods in terrestrial magnetism. 3. The periods demonstrated by Perrey to be connected with the moon's phases. 4. That discovered by Palmieri for Mount Vesuvius, the violence of whose eruptions perceptibly increases twice in the solar day in a manner similar to the ebb and flow of the tide. Both these latter may possibly be actual laws, though the modes of their connection are quite unknown and are likely to prove very complicated. 5. The quasi-periodical alternation of force announced by Mallet in his fourth report, such that a season of many severe shocks is followed by one of very few and sometimes slight shocks. 6. Mallet also detects indications of an increase in the frequency of earthquakes about the middle and end of each century. 7. The periodicity suggested by the facts first published by Humboldt, who remarked that in Mexico, South America, and the United States, the centres of earthquake influence seem to change their positions. Perrey and Mallet, agreeing with Miraldi and with the ancient traditions of Italy, announce the same fact for that peninsula; in it the numerous earthquake centres follow the general line of the ridges of the Apennines, as indeed Mallet has shown to be the rule over the whole world; but further it is shown that in Italy each of these centres has apparently a slow secular movement along the general line, so that its greatest energy is not recurrent at the very same spot, or not until after a long period.—*Physical Changes produced by Earthquakes.* Permanent upheavals and depressions affecting the physical geography of large regions of the earth are considered as being on an extended scale manifestations of the same force that suddenly elevates and depresses smaller districts at the moment of an earthquake. Dana, Lyell, and others, presume that extended changes take place with extreme slowness and comparative quiet; and Prévost, Dana, Mallet, and others, attribute these to the influence of tangential pressures and to the slow cooling and contracting of the earth. Beaumont and others ascribe the elevation of the great mountain chains to single upheaving shocks, with of course accompanying earthquakes of the greatest severity. The former views have now far more adherents, they being more in accordance with the customary modes of operation in nature; it is however not to be denied that both methods of operation are admissible. Of sudden changes may be noticed the elevations during the earthquake at Concepcion in 1835, and the depressions attending the shock at Lisbon in 1755. Of slow movements we find examples in the upheaval of the Scandina-

vian peninsula, which is now proceeding at the rate on its eastern coasts of five feet per century. About one half of the islands of the Pacific ocean are believed to be rising, as also the island of Spitzbergen, the West Indies, and the whole of the W. coast of South America. Among the most remarkable slow depressions are the case of the southern portion of Greenland, the numerous coral-reefed islands and atolls of the Pacific, and the countries of Holland, Belgium, Denmark, and the S. shore of the Baltic sea. In North America the most notable well established case of depression is that now in progress along the Atlantic coast from Cape Cod to Cape Hatteras, which region is calculated to be sinking at the rate of about two feet per century.—*Earthquake Waves.* This term is commonly applied to the great oceanic waves that attend such earthquakes as originate under the ocean. These waves while in deep water are merely very long but decided swells; in traversing shoal water they become more marked, and on nearing the shores often break most disastrously upon them, being in this case preceded by a rapid fall of the water, as is the case in ordinary breakers. The numerous cases that have been cited in a former section of this article suffice to show how prominent a feature of a disastrous earthquake are these sea waves. On account of their sudden definite origin and their vast size, these waves have on several occasions afforded a reasonable basis, in connection with the received principles of wave motion, for an approximate computation of the average depth of the sea over which they may have passed. A fine example of such a computation was given by Prof. Bache in the case of the waves that rolled into the harbors of Simoda, Osaka, Peel's island, San Diego, and San Francisco, in December, 1854. These waves apparently started from a point near Simoda, and on reaching the American coast were recorded on the self-registering tide gauges of the coast survey. The crest of the highest wave experienced at Simoda was 30 ft. above the average sea level at 9h. 30m. A. M., local time; the highest at San Francisco was 0.45 of a foot above the normal height of the water, and occurred about nine hours after the wave at Simoda. From these and other data Prof. Bache concluded the mean depth of the intermediate Pacific ocean to be between 2,100 and 2,500 fathoms. The wave attending the Arica earthquake of Aug. 13, 1868, also extended over the entire Pacific ocean; from the records at four tidal stations of the United States coast survey, and the observations made at eight other points, including Australia, Hilgard (1872) concluded that the eastern equatorial portions of the Pacific are the deepest, while the depth of the northern portions seems quite small.—*Nature of the Earthquake Shock.* The discovery of the true nature of the earthquake, to say nothing of its ultimate origin or cause, for a long time baffled the labors of mankind; the application of a purely inductive train of

reasoning has always been difficult, because of our own inability to experiment on the earth on so large a scale as was necessary, and because of the absence of exact observations and records. The principal results arrived at previous to or independently of Mallet's dynamical studies have been already given in the generalizations under the head of geographical distribution, &c. The history of the numerous hypotheses and crude theories that have been advanced from time to time in reference to the nature of the earthquake shock may be thus briefly summarized. Up to the beginning of the 17th century no views other than the most indefinite and superstitious notions seem to have been propounded and accepted. In 1679 Travagini suggested that the successive shocks are pulses of force. Flamsteed in 1693 considered that vibrating air caused the earth to tremble, as in ordinary thunder. During the 18th century Buffon and others used the term concussion in speaking of the movement of the earth; and an anonymous French author in 1756 maintained that chains of mountains are long levers, so that a slight movement at one end will be felt as a blow or earthquake shock at the other. Since this period all students have recognized the phenomena as those of a concussion, except perhaps Michell, who in 1760 announced his theory that the surface of the earth heaved like the swell of the ocean, or even like a wave; a view adopted in some respects in 1843 by H. D. and W. B. Rogers to explain the plication of the strata of the Alleghanies. In 1807 Dr. Thomas Young suggested the probability that the motion of the earth at any point is a vibratory one, and that it is propagated through the earth in a manner analogous to that of waves of sound; but he appears to have made no clear distinction between the subterranean waves of shock and sound. Similar views were adopted in 1823 by Gay-Lussac. In 1846 Mallet published his work on "The Dynamics of Earthquakes," in which, without specially indicating the ultimate origin of the earthquake, he very clearly presents views that are now widely accepted as to the true nature of the phenomena observed at the surface of the earth. These views are substantially as follows: An earthquake is the passage past the observer of a wave of elastic compression, in any direction from vertically upward to horizontally through the crust and along the surface of the earth, from any centre of impulse or from more than one, and which may be attended with sound and tidal waves depending upon the circumstances of the original impulse. When the wave of compression is passing through a solid stratum, each particle of the earth performs a vibratory movement similar to that made on the passage of a wave of sound, moving forward and returning in an elliptical or a more complicated curve. When the shock reaches the earth's surface the vibration of the particles at any point

may be somewhat to the right or left of the line of propagation from the origin of the impulse, owing to unequal strains or other disturbing causes; but in the main it is simply forward during the first half of the orbit (the first semiphase), and backward during the latter half, and therefore nearly in a straight line. The forward and the return movements when at their maximum velocities are generally almost precisely in a line with the direction of the propagation, and it is at these moments of maximum velocity that the destruction of walls, &c., by the earthquake is accomplished. During the forward movement occurs also the greatest velocity in the upward direction. The downward movement of the earth accompanies the backward or the latter half of the pulse; but the backward movements are generally slower than the forward, and therefore have a less destructive effect. The twisting of isolated blocks, which had by many been ascribed to a circular or vorticose movement of the earth, is in reality, as Mallet shows, the effect of a simple direct stroke acting in connection with the inertia of the body and the friction at its base as a mechanical couple. When the origin of the impulse is vertically beneath the observer, the movement of each particle of the earth about him will be mainly in the vertical direction; when the origin is at a distance, the movement will be more or less inclined to the horizon; and if by a proper seismometer we determine for several places the azimuthal direction and the angle of emergence of the pulse, it becomes possible to fix exactly the position of the origin. The destruction of walls, moving of solid bodies, &c., are therefore due not to the velocity of transit or that with which the shock passes along over the earth's surface, but to the velocity of the movement of each particle of the surface of the earth in its small elliptical orbit. The velocity of translation depends on the elasticity of the rock or earth, but rapidly diminishes in proportion as the rock is discontinuous or non-homogeneous; it is therefore generally different in each direction. The wave of shock or the pulse of compression is reflected and refracted on encountering a new stratum of different elasticity, precisely as in the case of sound. So also phenomena of interference can arise, and it is in such cases that the pulses cease to be rectilinear or elliptical, and become more complicated curves. When the earthquake originates under the bed of the sea, the vertical shock communicated to the waters causes a wave or a swell, often of large extent, that spreads outward in all directions with a velocity varying with the depth of the ocean at the point over which it may be passing, and which on reaching shallow water rushes along as a breaker preceded by a fall or a recession of the water. In earthquakes of this kind, therefore, there may proceed from a single origin (the seismic focus) within the earth a great wave of compression (the wave of shock)

and, accompanying it, a wave of sound; both waves will before they reach the observer be transformed by the influence of discontinuity and non-homogeneity into a complicated mixture of strong and weak shocks and loud and feeble noises. The sea water first affected by the shock will receive and propagate waves of sound, small forced waves of water, and the large swell which ultimately becomes the great earthquake wave, all of which will reach the observer on the land at different moments, depending on their respective velocities. The disturbance having passed through the ocean upward to the atmosphere must communicate to it the three sorts of waves already existing in the water, but of these the sound wave is the only one that is perceived. This completes the entire phenomena of an earthquake so far as relates to the shocks and sounds. When the impulse originates under the land, there is wanting from the preceding enumeration of six classes of waves or pulses only the great sea wave; all the others may be present, but if the shock extends with severity to the shore of a sea, the small forced waves that will arise may be of considerable magnitude, while the vertical stroke that was in the former case expended in producing the great sea wave now expends itself on terrestrial objects. The preceding views, as elaborated by Mallet, and in part adopted by Hopkins in his report of 1847 to the British association, were very generally accepted, but partook somewhat of a hypothetical nature, because of the scarcity of accurate observations of actual earthquakes, till 1862, when Mallet published the details of the methods and results of his investigation of the Neapolitan earthquake of 1857, to the study of which he had devoted much time at the expense of the royal society. In this investigation, the great importance of which as well as its complete success justifies our detailed attention, Mallet has established the science of seismology upon an immutable basis of accurate observation. By using the fissures in buildings, the disturbances of heavy objects, &c., as natural seismometers, and by proper selections of representative cases, he was able, with the mathematical assistance of the Rev. Samuel Haughton, to fix from 177 determinations the position of the seismic focus or origin of the disturbance as being a cavity beneath the village of Caggiora near Potenza. From 26 determinations of the angle of emergence he found the mean depth of the cavity to be $5\frac{1}{2}$ m. beneath the sea. Lines of equal seismic disturbance being drawn, he showed the earthquake to have desolated a region larger than any of which we have exact knowledge. The refractions and reflections of the wave of shock in encountering various strata were clearly shown. From the number and directions of the sounds and shocks he deduced the general form and position of the focal cavity, and showed that it must have been of the nature of a curved fissure whose height was 3 m., length 9 m., and

thickness very small. The amplitude of the vibrations of the particles at the surface of the earth near the seismic vertical was deduced as 2.5 in.: at a greater distance it was found to be somewhat greater, and Mallet remarks that it thus becomes evident that the earthquake is itself not an agent capable of directly producing any considerable permanent elevation of the land, but that it occurs along with and as part of a train of circumstances that do occasionally produce such elevations. The velocity with which the shock is propagated along the surface, or the velocity of transit, was found from seven determinations to vary between 989 and 658 ft. per second, depending on the nature of the strata concerned. This agrees well with other determinations made by Mallet in England and Schweitz in Hungary; but the velocities are 300 ft. less than those found by Nöggerath in southern Germany, where however different strata come into consideration, and Mallet has shown that owing to discontinuity and other causes the actual velocity of translation may be so low as one tenth of that which would take place were the rock continuous. These velocities refer to the surface of the ground, and require a slight increase in order to obtain the true velocity normal to the front of the wave. The maximum velocity of the wave particle in its orbit, or the velocity of the shock itself, was determined in 13 cases; the results vary from 9.8 to 21.2 ft. per second, their mean being 12.4 ft., and only three of the determinations materially differ from this. There were strong indications of a diminution of wave velocity with increase of distance from the focus. It is therefore evident that the velocity of the shock that causes the destruction during an earthquake is far less than the rapidity with which it is propagated. It is not necessary to presume that a similar velocity prevails in all other earthquakes; indeed, in the case of the tremendous shock at Riobamba in 1797, Mallet shows that the velocity of the shock must have been about 80 ft. per second, and this is very probably one of the most violent on record. Owing to the imperfect elasticity of the earth, the return movement in the orbit of each particle is not so great or rapid as the forward movement; in two cases Mallet was able to determine the existence of a slight difference of this kind. A definite idea of the severity of the maximum shock experienced during this earthquake may be formed by considering that it was such as would have been given to an obstacle run into by a locomotive moving at the rate of 10 m. per hour. The nature of the fleeting earthquake forces that instantaneously desolate the earth having been thus most successfully investigated by Mallet, the same path has been followed by Oldham in an equally successful and instructive manner in reference to the earthquake of Cachar, India, on Jan. 10, 1869; but the details of this work have as yet been only partially published.—*The Origin of Earthquakes*. If our ideas as to the true nature of

earthquakes have but recently come into some degree of accordance with the truth, still more is this the case with our views as to their ultimate cause and origin. On this difficult subject it might still be hazardous to offer any conjectures, were it not that the many unsuccessful attempts of the past have resulted to a certain degree in limiting our views to one or two causes that are not improbably in continual and effective operation. The theories relative to the origin of earthquakes may be divided into two classes: first, those that relate to the immediate active cause of all classes of earthquake motions; second, those that relate to the origin of the internal heat of the earth. The views of the first class have already been incidentally partially indicated in the preceding section. Considering them chronologically, we come first to the ancient indefinite notion of a blow or concussion somewhere within the earth, which was more definitely explained by Fromondi (1527) and by Travagini (1679). In 1693 Flamsteed suggested that explosions of gas communicated tremblings to the air and thus to the earth; in which view he was followed by Amontons (1703), who invoked heated air as the exploding gas. Lister regarded lightning and earthquakes as the results of the firing of "the inflammable breath of pyrites," i. e., sulphur; and Lémery (1700) considered earthquakes to be due to the explosions of any chemical mixtures containing sulphur and iron. Bouguer also invokes the inflammation and explosion of gases. Stukely (1750) finds their origin in electrical discharges within the earth, in which he is followed by Beccaria, Donati, Percival, and Priestley; and even Humboldt and Poey do not deny the possibility of some connection with electricity. Buffon held that caverns exist in the interior of the earth, and that the falling of their ceilings down upon their floors produced the initial concussions and noises; Humboldt, Darwin, and others, have shown that such caverns may have some connection with earthquakes, though not necessarily in the manner indicated by Buffon. The theory of the Rev. J. Michell (1760) demanded the sudden formation or condensation of aqueous vapor between the crust and the molten interior of the earth, and the passage of waves of this vapor in between the sedimentary strata of the crust, lifting the upper strata in waves like those of a carpet when it is gently shaken on the floor. In 1785 Dolomieu explained how water penetrating into the interior of *Ætna* might flash into steam, producing eruptions and earthquakes; this idea, extended by Bakewell (1813), has since become a favorite with many, and in some shape or other probably has been the prevailing one of the past 30 years. To meet certain very serious objections to Dolomieu's theory, Serape (in 1825 and 1872) considers that the water is already in place, being confined in cavities within the earth, long before a given earthquake, but that it is exploded into steam by

the heat conducted from some source perhaps at a great horizontal distance; he thinks that no concussion in the proper sense of the word takes place, but that when the expansive power of the water and vapor overcomes the adhesion of the rock and splits it, then the sudden tearing is accompanied by a reaction, giving rise to waves of shock, sound, &c. The idea of the formation of fissures as the result of protracted increasing tension seems also to have been adopted by Hopkins, Darwin, and others. In 1834 Keferstein, and in 1836 Sir John Herschel, independently of each other, advocated certain views that have been more elaborately treated by many geologists, such as Hunt (1858-72), Sorby (1863), Deville, Naumann, Forbes, and Daubrée. Starting with a suggestion of Scrope and Babbage that the heat slowly conducted from the solid interior of the earth would be concentrated near the surface under the increasing accumulation of sedimentary deposits that are poor conductors of heat, these chemical geologists show that such heat would probably slowly bring about chemical changes, metamorphism, evolution of gases, the transformation of the strata into a pasty mass of lava, and the explosion of the confined water, if such existed or were formed by the chemical changes. In 1854 Zantedeschi maintained that the fluid nucleus of the earth and the exterior thin crust are subject to solar and lunar tides, the crust being flexible like a thin sheet of iron; and that the upward pressure against the crust of a high tide in the interior ocean of lava elevates and cracks the solid strata, causing earthquakes and volcanoes. These hypothetical tides have been rendered quite improbable by the researches of Hopkins and Thomson. Lamont (1862), Varley (1870), and Sumichrast (1871) have connected together the phenomena of terrestrial magnetism and earthquakes, and have expressed the belief that the latter are due to magnetic action. The earlier papers of Mallet (1846 and 1862) made highly probable the general truth of the theory that the sudden expansion of steam under high tension is the immediate cause of the earthquake; he showed that the phenomena of the earthquake of 1857 may be thus explained in a very reasonable manner; but in 1873 he concludes that more causes than one may and probably do produce these concussions, as will be seen in our next section.—The second class of theories of the origin of earthquakes includes those that seek for the source of the internal heat of the globe. Passing by the ancient idea of internal fire, we come to Lémery (1700), Lister, Boyer, Breislak, Sir William Hamilton, Sir Humphry Davy, Daubeny, and many others, who attributed the heat to some form or other of internal chemical changes. Stukely (1750) and his followers sought its origin in electric currents. The nebular hypothesis of Laplace (1780) afforded Poisson, Scrope, Hopkins, Lyell, Phillips, and others, a base for the idea,

now widely accepted, that the present internal heat is but the remnant of that which prevailed when the earth was in its original condition of entire fluidity, and which it has slowly lost by radiation. Finally, when the mathematical investigations of Sir William Thomson had confirmed the idea of Hopkins that the earth must be in general solid, perhaps even to the centre, and when the ideas of permanent internal lakes of lava and of areas of special heat were beginning to be looked upon as too purely hypothetical, Mallet (1873) has with great success undertaken to solve the problem, and his views, covering as they do the whole field of vulcanicity, seem to meet with universal approbation. He shows that the secular cooling of the earth, supposing it to have been once a hot fluid globe, gave rise at first to a thin crust, whose contraction while thin was more rapid than that of the interior, thus causing it to be torn into segments by forces of tension; but that as the crust thickened it became subject to strains of the nature of tangential pressures as soon as the interior began to contract more rapidly than the exterior (the existence of such pressures was first pointed out by Prévost in 1835); the bending and crushing consequent upon these crushing pressures formed the chief mountain chains and ocean beds, as urged by Prévost, Dana, and others; the nucleus shrinking more than the shell, and the latter not being able to resist the strain upon it, it must crush and sink down upon the shrinking nucleus, the crushing being more or less paroxysmal; this crushing is accompanied by an immense evolution of heat, the quantity of which may be calculated by means of the theorems of the mechanical theory of heat, in connection with experiments instituted by Mallet (the heat resulting from crushing is a reality; that which Vose in 1866 suggested as resulting from pressure only cannot exist unless the pressure produce crushing or sudden compression); this heat, acting on the already heated interior, abundantly suffices to melt the adjacent portions thereof, producing lava, or to convert water into the steam that produces both earthquakes and volcanic eruptions. Mallet has made such experiments on the crushing of rocks and such calculations for all the volcanoes of the earth as prove that of the telluric heat known by the observations of the temperature of the earth to be annually dissipated into space, one fourth part is sufficient to account for the annual volcanic energy. He discerns therefore in the secular cooling of the earth and crushing of its shell a true physical cause for the earthquake; the crushing goes on *per saltum*, and is attended with either partial permanent elevations or with heat sufficient to melt rock and produce volcanoes and earthquakes. The function of the earthquake and volcano is thus seen to be preservative and not destructive; these are the instruments by means of which the solid crust of the globe

is kept in a state to follow down after the shrinking nucleus; little by little they accomplish in each locality a work that would otherwise be accomplished by sudden and terrible paroxysms overspreading the whole earth.—*Earthquake-proof Buildings*. The views of Mallet as to the nature of the movement of the surface of the earth during an earthquake shock have enabled him to define certain principles according to which buildings may be constructed so that they shall be able to resist any shock that is likely to visit them. These principles have been already applied by Mallet and Stevenson in the construction of light-houses for the Japanese government, and by Mr. W. Lloyd in the construction of the new custom house at Valparaiso.

EARTHS, the oxides of the metals aluminum, glucinum, thorium, zirconium, lanthanum, erbium, and yttrium, called alumina, glucina, &c. They are often called the earths proper, to distinguish them from the alkaline earths, baryta, strontia, lime, and magnesia, the oxides of the metals barium, strontium, calcium, and magnesium. Before the decomposition of some of them by Sir Humphry Davy they were thought to be elements. Silica was formerly regarded as an earth; but on account of its forming definite compounds with the earths in which they act the part of bases, it must be classed as an acid. The earths generally exist in nature in combination with silica; although in the varieties of corundum, such as the gems sapphire, ruby, oriental topaz, and oriental amethyst, alumina exists principally as oxide, the Indian sapphire having the composition Al_2O_3 , 97.5 per cent.; magnesia, 1.9; silica, .8 per cent.; and the Indian ruby containing barely more than 1 per cent. of silica. In feldspar alumina is found combined with silica, sometimes with silicate of soda, but more frequently with silicate of potash. The gem hyacinth is composed of silicate of zircon. The silicate of glucina is found in the beryl and erbium. Associated yttrium is found, combined with silica, in the mineral gadolinite.

EARTH WORM (*Lumbricus terrestris*, Linn.), an articulate animal belonging to the abranthiate division of the class of annelids. (See ANNELIDA.) This well known worm has a long, cylindrical, contractile body, divided into many apparent rings (sometimes 150) by transverse wrinklings; the internal surface of the muscular envelope sends off annular septa, dividing the cavity of the body into as many chambers as there are segments, the partitions having openings which allow the passage of the contents of the general cavity from one chamber to the others. Each segment is provided with setæ or bristles, beginning at the 14th ring from the head, four on each side, united in pairs, forming eight longitudinal rows, of which four are lateral and four inferior; they are short and rough, and are used as fulcra during creeping or climbing in the

ground. The sense of touch is very acute, as is shown by the quickness with which they retire into the ground when touched, or at the jar produced by an approaching footstep; the sense is believed to be most acute toward the head, especially in the first segment. The eyes are wanting. The mouth is near the anterior extremity of the body, without teeth, with two somewhat prominent lips; the pharynx is simple, short, and muscular, the œsophagus narrow, the stomach very muscular, and the intestine short, straight, constricted by the muscular septa, and opening at the posterior extremity of the body. The blood is red, and the circulation is complete and closed; the several pairs of simple, transverse canals, situated above the stomach, whose pulsations may be distinctly seen, may be considered the heart. The dorsal vessel lies upon the intestinal canal enveloped in the hepatic tissue. The blood, though red, is quite different from that of the vertebrates; according to Siebold, it contains colorless, spherical, unequal-sized granular globules; these, Quatrefages says, are not part of the blood, but belong to the fluid of the general cavity; the latter maintains that the coloring matter is in simple solution. There is no apparent external organ of respiration, and the peculiar canals in the abdominal

Earth Worm (*Lumbricus terrestris*).

cavity are regarded by some as internal branchiæ or aquiferous vessels. The structure of these organs is little understood; but in all genera of the division there are at the commencement of the intestine very tortuous canals, opening generally on the ventral surface; these canals are lined with ciliæ, which have an undulatory movement always in one direction; they never contain air, according to Siebold, but circulate an aqueous respiratory fluid by means of the ciliæ; even the terrestrial earth worms can live only in damp earth, from which they obtain the necessary aqueous fluid. In the *lumbricus* these canals are surrounded by a distinct vascular network; they appear to end in loops, and their external orifices have not been satisfactorily ascertained. The most probable opinion is that the respiration is carried on principally by the general integument, and partly by the vascular system on the walls of the intestine; the ciliated canals described by Siebold are believed by Quatrefages to be organs for the secretion of the mucus which invests the body; but Dr. Williams, in his "Report on the British Annelida" (1851), considers them as utero-ovaria. The *lumbrici* reproduce by sexual organs; their eggs are spherical and present nothing

remarkable; the sexes are united in the same individual. During the breeding season, from six to nine of the segments (from the 26th to the 37th, as generally described) are developed into a kind of collar, nearly surrounding the body, by which these animals seize each other during coition; its component glandular follicles secrete a whitish viscid fluid, probably used for the formation of their cocoons or egg cases. According to Dufour, these cocoons have a long narrow neck, each, in the largest species, containing from one to six eggs; the statement of Montègre that the young are born alive seems to be confirmed by the observations of Dr. Williams, who says that they escape from the egg before leaving the body of the parent. It seems certain from the experiments of Dufour (*Annales des sciences naturelles*, t. v. p. 17, and t. xiv. p. 216, 1st series) that the earth worm reproduces by means of eggs; he describes them as an inch in length, of a corneo-membraneous consistence, deposited in the earth at a depth of from 6 in. to 6 ft., in localities where the soil is neither inundated nor too dry, isolated, and each egg containing one or two young. Earth worms live in moist earth, in which they make galleries in all directions, swallowing the earth as they proceed; their food is principally soft and decaying vegetables, as may be proved by any one who chooses to watch a garden walk by the light of a lantern on a damp evening, when they may be seen creeping out of their holes, elongating their first tactile segment, feeling in all directions for food, and, seizing upon any suitable substance that presents itself with their projected proboscis, retiring backward into the ground; their constant presence in situations where there is decaying vegetable matter proves that their food is principally derived from such substances; they also, as Montègre observed, feed on animal matters; it seems more reasonable to believe, with De Blainville, that they swallow earth for the purpose of making progress in their galleries, than that they do this to extract humus or any other nutritious substance from it. They seek each other chiefly at night and in the latter part of spring, though some species have been noticed together at all times of the day, and during all the warm months; it is well known that they are most abundant on the surface of the ground during and after nocturnal rains. It has long been believed that this animal possesses a remarkable power of reproducing parts lost by accident or design, even to the extent of forming perfect individuals from separated portions; the experiments of Dugès prove that very important parts may be reproduced, and it may easily be believed that in a worm divided into two, the anterior portion might produce an anus by the simple contraction of the wound; but that the posterior portion should be able to reproduce cerebral ganglia, mouth, stomach, cardiac and sexual organs, cannot be admitted; the anterior may survive a long time, but the

posterior division gradually dries up and dies. —Though occasionally marring the beauty of the garden walks by little hillocks of earth, they not only do not injure vegetation, but are useful in permitting air and water to penetrate the ground through the channels which they pierce in every direction, manuring the fields, and throwing up fine dirt around the roots of grass; a field in which no worms exist can be safely put down as of little value to the agriculturist; they are most active in spring, when most needed, and retire during winter deep into the ground; according to Mr. Darwin, they perform under ground that which the plough and the spade do on the surface, and have covered a field manured with marl, in the course of 80 years, with a bed of earth 13 inches thick. Worms also furnish food for birds, moles, frogs, and other small animals, and are used as bait for many kinds of fish. The rapid ascent and descent of worms in the ground are easily understood from the action of their numerous setæ; they have often been seen high up on perpendicular surfaces, and in situations which they could not have reached without climbing perpendicularly. In their movements they display great muscular force, each seta being moved by its appropriate system of muscles, and being capable of penetrating a deal board; in ascending perpendicular surfaces of glass or other impenetrable material, they must retain their hold by means of the tenacious mucus with which their skin is covered. —There is no question that many species have been confounded under *L. terrestris* (Linn.). The largest European species is called *L. gigas*, and is 18 in. long, and as large as the little finger; other common and smaller species are *L. anatomicus* and *L. trapezoides*. Whether all the American species are distinct has not been sufficiently demonstrated. Those who wish to pursue this subject into its details are referred to the writings of Dufour, Dugès, Milne-Edwards, Blanchard, and especially Quatrefages in the *Annales des sciences naturelles* since 1828; to the article "Annelids," in the "Cyclopædia of Anatomy and Physiology;" to the report of Dr. Williams, above quoted; and to Siebold's "Comparative Anatomy."

EAR TRUMPET, an instrument intended to aid the hearing of persons partially deaf, although sometimes used by ordinary persons to intensify distant sounds. We have no means of ascertaining at what period or by whom ear trumpets were invented. The practice of putting the hand to the ear in a trumpet shape probably first suggested it, and from occasional allusions to the use of the trumpet in old writers it would seem to have been of very early origin. The earliest form of which we have any knowledge was a rude imitation on an exaggerated scale of the form of the external ear; but as this was found inconvenient from the difficulty of retaining it in place, a form more nearly resembling a speaking trumpet was substituted. This was modified by bend-

ing the tube and applying the mouth, turned forward and given an elliptical form, close against the ear. Another modification was a flat tube passing over the head and applied to each ear, while in front and immediately over the forehead was an opening to receive the sound. One inventor, having observed that in listening intently people opened their mouths, contrived a sort of plectrum or vibrating body to be held between the teeth, and thus to convey sounds by the Eustachian tube. After the introduction of caoutchouc and gutta percha into the arts, a long tube of one or other of these materials, with a bell-shaped trumpet at the end, took the place of the metallic trumpet, and for many purposes is very convenient. In England in some of the churches pews are constructed with tubes to conduct the sound, opening in convenient positions for the ear of the listener. Among the more recent inventions for facilitating hearing are the auricle, a small tube of silver with a semi-globular expansion, intended to be inserted into the meatus of the ear; and the tympanum, a small thin disk of rubber, having a silver wire passing through it to transmit the sound wave. In a few cases the latter has been of considerable service. In total deafness such means are of no advantage.

EARWIG, an orthopterous insect, of the family *cursoria* or runners, which also includes the cockroach; it belongs to the genus *forficula* (Linn.). All the six feet are formed for running; the wings are four, the upper pair very short, coriaceous like the elytra of coleoptera, without veins, enclosing the under wings, which are folded both longitudinally and transversely; the mouth is formed for mastication; the body is long and somewhat flattened, and armed at the hinder end with a pair of curved blades shutting like scissors or nippers; there are three joints to the tarsus; the antennæ are filiform. These insects undergo a partial metamorphosis. They seem to form the connecting link between coleoptera and orthoptera, resembling the former in their elytra, and the latter in the shape of the wings and mouth, and the metamorphosis; for these reasons most English entomologists adopt for them the order *dermaptera* of Mr. Kirby and Dr. Leach, considering them coleoptera with

greenhouse plants, and to pinks, dahlias, and other favorites of the flower garden. The full-grown insect, including its caudal forceps, is not quite an inch long, and its width is one sixth of an inch; the color is light brown. Being nocturnal, they creep in the daytime into any crevice or hole, and this has given rise to the popular belief that they enter the human ear; they might attempt this, but the waxy bitter secretion of the ear would probably prevent their entrance; there are no well authenticated instances of their doing this, and no harm could result if they did, as the drum of the ear would arrest them, and a drop or two of oil would soon destroy them by stopping up their respiratory tracheæ. The common way of catching them in England is by hanging up any convenient vessel or tube for them to crawl into in the morning, from which they are shaken and killed. In the larvæ there are no wings or elytra, but the skin is changed several times; the nymph differs little from the perfect insect; in both these conditions they are voracious, even devouring each other. In this country there are several species, rather uncommon, and never injurious to vegetation.—The many-footed creeping animal erroneously called earwig in America (genus *lithobius*) is not an insect, but a myriapodous crustacean, equally innocent of entering the human ear.

EASDALE, or **Eisdale**, an island on the W. coast of Argyleshire, Scotland, in the frith of Lorn, nearly adjoining the island of Seil, about $\frac{1}{2}$ m. long and of nearly the same width, noted for its slate quarries, which have been worked for nearly two centuries, and furnish annually more than 4,000,000 slates. The island consists entirely of slate, and has been so much cut away that a large part of it is now even with or below the level of the sea.

EASEMENT, a privilege which the owner of one tenement, called the dominant tenement, has in respect to another, called the servient tenement, by which he may require the owner of the latter to permit something to be done thereon, or to refrain from doing something, which otherwise as owner he would be entitled to do. It must be defined and limited in extent, and it must in some way be for the benefit of the dominant tenement, and not for some general benefit to the owner. Among the principal easements are rights of way, the right to carry water or to obtain light or air over the adjoining lands, the right to support of land or buildings by adjacent land or buildings, the right to have party walls and fences kept in repair, &c. In general, they must be created by deed or established by prescription, though every man has a natural right to the support of his land by the adjacent land of another, but not to the support of the artificial structures he may rear upon the land. Easements are lost by release, by abandonment, or by the dominant and servient tenements becoming united in the same ownership. Public rights

the metamorphosis and caudal appendages of orthoptera. They are common in moist earth, under stones, in decayed wood, and in similar damp and dark places; they are considered in Europe injurious to peaches, pears, apples, to

over the lands of private individuals, for purposes of travel and the like, are often spoken of as public easements.

EAST (Anglo-Saxon, *East*; the corresponding word in many other languages having a similar etymological significance), the quarter in which the heavenly bodies rise. Due east is the direction toward the east precisely at right angles to each meridian line; the reverse direction is due west. An object is said to bear due east when it is seen exactly in this direction, but it is said to be due east when it is on the same parallel of latitude as the observer. An object that is due east will in northern latitudes bear N. of E., unless it be very near the observer, because a line perpendicular to a meridian in any latitude, if continued in one direction as a great circle, would depart from the parallel of latitude and intersect the equator at a distance of one fourth of a circle. A column of smoke, for example, over New York city, could it be seen at Nauvoo, would bear 53° N. of E., and smoke rising from Nauvoo would bear from New York 53° N. of W. The bearing is the direction in which a great circle from the observer through the object starts from the observer; while the course or actual direction is the direction of a line to the object cutting every meridian at the same angle.

EAST BATON ROUGE, a S. E. parish of Louisiana, bounded E. by the Amite river and W. by the Mississippi; area, about 450 sq. m.; pop. in 1870, 17,816, of whom 11,343 were colored. The surface is level in the north and gently undulating in the south; the soil is moderately fertile. There are extensive forests of live oak, cypress, and magnolia. The chief productions in 1870 were 185,133 bushels of Indian corn, 3,163 of Irish and 32,075 of sweet potatoes, 8,967 bales of cotton, 833 hogsheds of sugar, and 59,497 gallons of molasses. There were 1,296 horses, 1,275 mules and asses, 3,203 milch cows, 5,936 other cattle, 3,470 sheep, and 7,819 swine; 1 manufactory of agricultural implements, 1 of boots and shoes, 2 of carriages, 1 of barrels and casks, 1 of cotton goods, 1 of gas, 10 of molasses and sugar, 1 of woollens, and 1 saw mill. Capital, Baton Rouge.

EAST BIRMINGHAM, Pa. See BIRMINGHAM.

EASTBURN. **I.** James Wallis, an American author, born in England in 1797, died at sea, Dec. 2, 1819. He graduated at Columbia college, New York, in 1816, and studied theology under Bishop Griswold at Bristol, R. I., with a view of taking orders in the Protestant Episcopal church. While thus employed he undertook a new metrical version of the Psalms, which he did not live to complete. In conjunction with Robert C. Sands he published in 1818 "Yannoyden," a romantic poem founded on the history of King Philip, the sachem of the Wampanoags. He also wrote several fugitive poems, some of which are very gracefully versified. In 1818 he was ordained, and was about to take charge of a parish in Accomac, Va. He sailed for Santa Cruz to restore his health,

but died a few days after embarking. **II.** Manton, an American bishop, brother of the preceding, born in Leeds, England, Feb. 9, 1801, died in Boston, Sept. 11, 1872. He came to America with his parents while a child, graduated at Columbia college in 1817, studied at the Episcopal theological seminary in New York, and was ordained deacon in 1822, and priest in 1825. He was for five years assistant minister in Christ church, and in 1827 became rector of the church of the Ascension, New York. At the close of 1842 he was consecrated assistant bishop of the diocese of Massachusetts; and in February, 1843, on the death of Bishop Griswold, he became bishop of the diocese. His principal works were: "Four Lectures on Hebrew, Latin, and English Poetry" (1825); two essays in a volume entitled "Essays and Dissertations in Biblical Literature" (1829); "Lectures on the Epistle to the Philippians" (1833); "Oration on the Semi-centennial Anniversary of Columbia College" (1837); and many sermons and pastoral charges. He also edited, with notes, "Thornton's Family Prayers" (1836). He bequeathed his property to the domestic missions in Massachusetts, to the Episcopal theological seminary in Massachusetts, to the American Bible society, and for other benevolent objects.

EAST BRIDGEWATER. See BRIDGEWATER.

EASTER (Germ. *Ostern*, old Saxon *oster*, *osten*, rising), the Christian passover and festival of the resurrection of Christ. The English name is probably derived from that of the Teutonic goddess of spring, Ostera or Eostre, whose festival occurred about the same time of the year as the celebration of Easter. The Hebrew-Greek word *πάσχα* has passed into the name given to this feast by most Christian nations. The French call it *Pâques*, the Scotch *Pasch*, the Dutch *Paschen*, the Danes *Paaske*, and the Swedes *Påsk*. St. Paul calls Christ "our Pasch;" and both the eastern and western churches from the beginning distinguished a twofold event in the Easter commemoration, the slaying of "the Lamb of God" and his resurrection; hence the terms in their liturgies, *pascha crucifixionis* and *pascha resurrectionis*. And the distinction between the day on which Christ died and that on which he rose again had not a little to do with the Easter controversy in the early church, originating in a difference of custom with regard to the day of the week and the day of the month on which Easter should be celebrated. As the Christians held that Christ, the true paschal lamb, had been slain on the very day when the Jews in celebration of their passover immolated the figurative lamb, so, both in the West and in the East, those who believed the Christian passover to be a commemoration of Christ's death adhered to the custom of holding the Easter festivity on the day prescribed for the Jewish pasch. Now, as the Jews celebrated their passover on the 14th day of the first month, that is to say,

the lunar month of which the 14th day either falls on or next follows the day of the vernal equinox, all Christians who persisted in following this custom in the celebration of Easter came to be called quartodecimans or "fourteenth-day men," or, still more opprobriously, Judaizing Christians. The great majority of Christian churches, attaching most importance to the day of Christ's resurrection, which was the first day of the week (hence called the Lord's day, our Sunday), held to Easter's being celebrated on that day, and on the Sunday which followed the 14th day of the moon of March, the day on which Christ suffered. This question, one of custom and local discipline in the beginning, had given so much trouble that about 158 Polycarp, disciple of St. John the Evangelist and bishop of Smyrna, went to Rome to consult with Pope Anicetus on the means of healing the difference. In the council held in Rome on this occasion, the western or present manner of celebrating Easter was affirmed; but Polycarp departed with the full friendship of the pope and in the communion of the church of Rome. Gradually, however, the question of the Easter celebration from one of discipline became one of dogma. In 182 a priest called Blastus made himself very obnoxious in Rome by endeavoring to have the Jewish rule of celebrating Easter on the 14th day of the moon of March adopted as a rule of faith. The discussion throughout the Christian world had become so angry that Polycrates, bishop of Ephesus, appealed to Victor, bishop of Rome, asking to have this matter decided once and for all. Councils were at once assembled in Gaul, Pontus, Osroene, Achaia, and other countries, as well as in Rome. The result was a decision fixing the feast of Easter, or the resurrection, on the Sunday immediately following the 14th day of the March moon. Polycrates refused to acquiesce in this decision, because it involved an abandonment of the customs of his fathers. The decree of excommunication pronounced against the quartodecimans by the council of Rome was held in abeyance, at the prayer of Irenæus of Lyons; and a schism was thus averted. After this the contending parties agreed to maintain their respective customs and practices in this respect without censuring one another. Constantine had the subject brought before the council of Nice, in 325. The question was fully discussed, and finally settled for the whole church by adopting the rule which makes Easter day to be always the first Sunday after the full moon which happens upon or next after March 21; and if the full moon happen on a Sunday, Easter day is the Sunday after. By this arrangement Easter may come as early as March 22, or as late as April 25. In France the year began with Easter from the 12th century till 1564, for which year Charles IX. fixed Jan. 1 as the first day.—This sacred festival has been termed the queen of festivals; it has been observed from the very beginning,

and is celebrated in every part of the Christian world with great solemnity and devotion. Formerly the churches were ornamented with large wax candles, and the Christians saluted each other with a kiss and the words "Christ is risen," to which the response was made, "He is risen indeed." This custom is still retained in the Greek church, particularly in Russia. The day before Easter Sunday, or Holy Saturday, has ever been set apart as a day for specially solemnizing baptism. Courts of justice were closed, alms were distributed, slaves were freed, and the people gave themselves up to enjoyment and feasting. In nearly all Christian countries the recurrence of Easter has been celebrated with various ceremonies and popular sports and observances. Among the best known is the custom of making presents of colored eggs, called pasch or pace eggs, which were often elaborately ornamented; and in a royal roll of the time of Edward I., preserved in the tower, appears an entry of 18*l.* for 400 eggs to be used for this purpose. Colored eggs were used by children at Easter in a sort of game which consists in testing the strength of the egg shells, and this practice is still continued in most Christian countries. In some parts of Ireland the legend is current that the sun dances in the sky on Easter Sunday morning. This was once a prevailing superstition in England also, which Sir Thomas Browne, in his "Inquiry into Vulgar Errors," thought it not superfluous to declare unfounded. The game of ball was a favorite Easter sport, in which municipal corporations formerly engaged with due parade and dignity; and at Bury St. Edmund's within a few years the game was kept up with great spirit by twelve old women. In the northern counties of England the men parade the streets on Easter Sunday, and claim the privilege of lifting every woman three times from the ground, receiving in payment a kiss or a silver sixpence. The same is done by the women to the men on the next day.

EASTER ISLAND, an island in the eastern part of the Pacific, lat. 27° 6' S., lon. 109° 17' W., distant about 2,300 m. from the coast of South America. From its solitary position it has been but seldom visited. It was discovered in 1722 by Roggeween, a Dutch navigator, and was visited in 1774 and described by Cook. It is about 11 m. long and 6 broad, and contains three extinct volcanoes of large size, rising to the height of 1,200 ft. above the sea. The land in the valleys is fertile and well cultivated; but the island is deficient in water. The natives, who number about 1,000, are tall and robust, with regular features and dark complexion. They belong to the Polynesian race, and until lately were fiercely hostile to the whites. In 1865 some French missionaries landed among them, and, though at first treated with great rudeness, finally succeeded in converting them to Christianity, which is now professed by the entire population.—The remarkable feature of the island is that it con-

tains several hundred gigantic stone statues, tolerably well chiselled. The largest of these are 40 ft. high, and measure 9 ft. across the shoulders. Many of them stand in the crater of the great volcano, while others are scattered about the island, generally prostrate. They were cut from the common rock of the island, and many unfinished statues are yet to be seen in the quarries. Nothing is known of the origin of these statues. They were certainly not made by the present race of inhabitants, who have no tools adequate to their sculpture, nor any means of moving such huge masses. The native traditions about them are puerile, and seem to ascribe them to a supernatural origin. The conjecture has recently been advanced that the island is the remnant of a submerged continent, and that the statues were made by an extinct people who worshipped their idols in high places, and to whom the craters of volcanoes were peculiarly sacred.

EASTERN EMPIRE. See **BYZANTINE EMPIRE.**

EAST FELICIANA, a S. E. parish of Louisiana, bounded N. by Mississippi, E. by the Amite river, S. W. by the Mississippi, and W. by Thompson's creek; area, about 500 sq. m.; pop. in 1870, 13,499, of whom 9,393 were colored. The Clinton and Port Hudson railroad extends from the capital to the Mississippi river. The surface is moderately uneven, and the soil is well watered, fertile, and easily tilled. There are forests of pine, oak, and bay. The chief productions in 1870 were 167,262 bushels of Indian corn, 26,263 of sweet potatoes, 10,252 bales of cotton, and 5,900 lbs. of rice. There were 1,147 horses, 890 mules and asses, 2,155 milch cows, 3,954 other cattle, 2,284 sheep, and 5,637 swine. Capital, Clinton.

EAST INDIA COMPANIES, associations formed to conduct trade between Europe and the Indies. The overland trade, in which the Italian republics were foremost, was terminated by the Turkish conquest of Constantinople and Egypt. The necessity of a new route to India then became the problem of western Europe, and Vasco da Gama rounded the Cape of Good Hope and reached the Malabar coast in 1498. The Portuguese then established themselves in India, and for nearly a century monopolized its trade. Portugal being united with Spain in 1580 and its ports closed to British vessels, the English bought their Indian supplies of the Dutch. But when on the revolt of the Netherlands Dutch vessels also were excluded from the port of Lisbon, both Dutch and English established direct trade with the Indies. In 1587 a charter was granted to a Portuguese company, in consideration of an annual tribute. On the breaking out of the war between England, Holland, and Spain, which struck a disastrous blow at the India trade, the Portuguese company became unable to pay its annual tribute to the government, and was abolished in 1640. In 1595 a "Company for Remote Parts" was formed at Amsterdam, which in 1602, having been united with other

companies, received a charter from the states general conferring on them the exclusive privilege of trade to the East Indies for 21 years, with the necessary civil and military powers. They began with a capital of 6,500,000 guilders, and in 20 years their dividends amounted to 30,000,000 guilders, besides vast amounts of property in colonies, fortifications, and vessels. The charter was extended to 1644; Batavia was founded; the commerce with Japan, which returned silver and copper for commodities, was extended; in 1641 Malacca, capital of the then neglected Portuguese East India possessions, was acquired by the Dutch; and from 34 to 41 freighted vessels were sent out annually, of which from 25 to 34 returned loaded. Yet so rapidly did the English and French commerce increase during these years, that in 1644 the Dutch East India company could scarcely command the 1,600,000 guilders required as a subsidy to the government, on again renewing its charter for 21 years. The peace of Westphalia, which secured the independence of the republic of the United Provinces, once more gave the company life. In 1665 the charter was with much opposition renewed till 1700. At this time the company held the principal seats of commerce in Ceylon, Sumatra, Java, Borneo, and in fact throughout the Indian archipelago, and had large colonies in South Africa. They commanded the trade with Pegu, Siam, Tonquin, Japan, the Banda and Molucca isles, Amboyna, &c. Batavia was then in all its glory, and the straits of Sunda on which it is situated had become, instead of those of Malacca, the channel to the further Indies. The charter was renewed in 1701, in 1741, and in 1776, the last time for 30 years, and on condition of paying down 2,000,000 guilders, with 360,000 annually. Turning their hands against every one in the East, and seeking, by oppression of natives, exclusion of Europeans, and the forced production of some spices with prohibition of the cultivation of others, to rule the markets of the world and to extend and consolidate their dominion and wealth, the company was yet so exhausted by war with England and political expenses, that in 1781 the states general were obliged to assist it with a loan. In the first French revolution it lost nearly all its possessions. The establishment of the Batavian republic in 1795 terminated its existence, and the affairs of the company passed into the hands of the government. A new company was established in 1824, called the *Handel Maatschappij* or trading association. This company became the agent for the sale of the government produce in Europe, and the carrier of this produce, and farmed some branches of the public revenue of Java and the other Dutch East India colonies.—A French East India company, founded in 1664 by Colbert, was broken up in 1770.—A Danish East India company, founded in 1618, was dissolved in 1634; it was reconstituted in 1670, and again dissolved in 1729. A new company, formed

in 1732 under the name of the Danish Asiatic company, was prosperous during the 18th century, but afterward declined.—The English endeavored to open commercial intercourse with India as early as 1553, during the reign of Edward VI., but without success. In 1599 a company of London merchants was formed, representing a capital of £30,133, which received a charter from Queen Elizabeth, Dec. 31, 1600, under the title of "The Governor and Company of Merchants of London trading with the East Indies." The charter was for 15 years, and granted the exclusive right of trading to all countries from the cape of Good Hope eastward to the straits of Magellan, excepting those which were possessed by friendly European powers. The first governor was Thomas Smythe, who was assisted by 24 directors named in the charter, which empowered them to elect a governor and directors and other office-bearers; to make by-laws for their government; to inflict punishments, corporal or pecuniary, on those in their employ, provided such punishments be within the laws of Great Britain; to export all goods duty free for four years, and to export foreign coins as bullion to the amount of £30,000 a year, £6,000 of the same being previously recoined at the mint; with the proviso that they must import within six months from the conclusion of every voyage after the first an amount of specie equal to that before exported. It was also provided that should the company not be found to the public advantage, its charter might be cancelled after two years' notice. The first expedition to India sailed under command of Capt. Lancaster, Feb. 15, 1601, from Torbay. It consisted of five ships, varying in size from 130 to 600 tons, having cargoes of bullion, iron, tin, broadcloths, cutlery, glass, &c. The entire venture, ships and all, was valued, at £69,091. It arrived at Acheen, Sumatra, June 5, 1602. Lancaster made treaties with the kings of Acheen and Bantam, and returned to the Downs Sept. 11, 1603, with cargoes of pepper and other produce. For several years the expeditions were not increased in size or value, but were generally fortunate in their results. In 1607 Capt. Hawkins was sent out to establish commercial intercourse with the dominions of the Great Mogul, but his mission proved of no avail. In 1612 Capt. Beal obtained from the court at Delhi several important privileges, among which was that of establishing a factory at Surat, which city continued to be the chief British station in India until the organization of Bombay. Factories were depots for goods, fortified, to protect the lives and property of resident representatives of the company. In 1613 the capital of the company was united; the largest stockholders took the management of affairs, and these were so prosperous that in four years the shares of the company rose to the value of 203 per cent., while its factories were extended to Java, Sumatra, Borneo, the Banda islands, Celebes, Malacca, Siam, the Coromandel and

Malabar coasts, but chiefly to the dominions of the Great Mogul, whose favor the company had finally secured. From the beginning of the company's trade to July, 1620, it had sent 79 ships to India, of which 34 had come safely home richly laden, 4 had been worn out in India, and 20 had been lost—2 by careening, 6 by sea perils, and 12 captured by the Dutch. At that time (1620) the capital of the company in ships, goods in India, &c., amounted to £400,000; it had exported from England to India the value of £840,376; had imported what cost £356,288 in India, which brought £1,914,600 in England; and finally quarrels with the Dutch, their most energetic rivals, had occasioned losses to the amount of £84,088. In 1616 a new stock subscription had been opened, and £1,629,040 were raised. But in 1627 complaints were made of abuses and bad management; during the reign of the Stuarts there was much murmuring against the monopoly, and Charles I. in 1635 gave to Sir William Courten and several private individuals the right to trade to India. In 1645 permission was given by the natives to the company to build Fort St. George at Madras. In 1655 Cromwell vainly attempted to make the East India trade free. In 1657 he renewed the company's charter, which was confirmed by Charles II. in 1661, who at the same time conferred on it authority to make peace or war with any power not of the Christian religion; to establish fortifications, garrisons, and colonies; to export ammunition and stores to its settlements duty free; to exercise civil and criminal jurisdiction in its settlements according to English law; and to seize and send to England all Englishmen found trading on their private account. In 1667-'8 the tea trade was begun, a branch of commerce which in a few years proved to be of vast importance to the company. In 1669 the island of Bombay was granted to the company by Charles II., who had received it as part of the marriage portion of the princess Catharine of Portugal. In 1676 a factory was established on the Hoogly in Bengal, which led to the foundation of Calcutta; and other factories were shortly started in that region. In 1677 the company received a renewal of its charter, with indemnity for past misuses, and permission to establish a mint at Bombay. In 1681, by a report of the governor, the company had 35 ships, of from 100 to 700 tons, trading between India and England, or coastwise in India; and the exports from England of lead, tin, cloth, stuffs, &c., amounted to from £60,000 to £70,000 a year. The trade was astonishingly small; the affairs of the company were not prosperous, and in 1688 the validity of its charter was questioned, but in 1693, after a heavy struggle, it was renewed. In 1694 a vote of the house of commons threw open the trade to all England. In 1698 a new company received a charter, conferring much the same privileges as those of the old one, for the consideration of a loan of £2,000,000 to the

state. The two companies were united in 1702 under the title of "The United Company of Merchants trading to the East Indies." They advanced a further sum to the state, making in all a loan of £3,200,000, at 3 per cent., in consideration of which their charter was extended until the expiration of a notice of three years, which could not be given sooner than March, 1726, nor until the money borrowed by government should be repaid. The act ratifying this was passed in 1708. By it the local affairs of the company were intrusted to the three councils of Madras, Bombay, and Calcutta, while the general direction was retained in England. Meanwhile, in 1698, a grant of Calcutta and two adjoining villages had been acquired, with the right of jurisdiction over the inhabitants, and leave to erect fortifications, which was immediately done; and in 1715 this jurisdiction was largely extended by grant from the emperor Ferokshere. In 1701 an act prohibited the importation into England of manufactured Indian goods. In 1732 the renewal of the charter was obtained with much difficulty; and in 1744 the company bought its extension to 1780 by a loan of £1,000,000 at 3 per cent. The territorial conquests of the company were inaugurated by the expulsion, in 1749, and ultimate protection of the rajah of Tanjore, he making some concessions of territory on each occasion of the British exercise of protection. In 1757 they deposed Surajah Dowlah, nabob of Bengal, gaining thereby several large and rich provinces. In 1761 the defeat of the French left the English free to pursue their schemes of aggrandizement in India. In 1792 Tippoo Sahib was compelled by Cornwallis to give up half his dominions, and £3,500,000 in bullion. In 1799 Seringapatam was taken, Tippoo slain, and some more territory annexed. Subsequently, by war with the Pindarees, with Burmah, Nepaul, and the Afghans, and by judicious protection, interference, and annexation, the company mastered the whole of Hindostan, with small exceptions. The sudden increase of territory and power in India threw everything into confusion. Corruption reigned everywhere. The revenues fell short of expenses, and in 1772 the company, notwithstanding its immense possessions and privileges, was obliged to raise a loan of £6,000,000 from the bank of England, and of £1,400,000 from government for current expenses. In 1773 reform was called for, but was only incompletely effected. In 1781 the privileges of the company were extended to 1791, with three years' notice; the dividend on its stock was fixed at 8 per cent.; £400,000 was to be paid as an annual subsidy to the government, and three fourths of the surplus revenue was to go to the government, one fourth to the company's use. Yet in 1780 the East India trade formed only $\frac{1}{3}$ part of the entire foreign trade of the empire. In 1783 the company was again so involved, on account

of wars, &c., as to be unable to pay the subsidy. In the following year, on the proposition of Mr. Pitt, a board of control was appointed, consisting of such members of the British privy council as the sovereign of England chose to appoint, the two principal secretaries of state and the chancellor of the exchequer being three of the members. The president was usually a cabinet minister. In 1793 the charter was prolonged to 1814. From that date the charter was again prolonged 20 years, but the trade to India was substantially thrown open, though the monopoly of the trade to China was continued, and did not cease till 1834. Parliament in 1833 granted a new charter, by which—1, the company ceased to be a trading association; 2, it was continued in the government of India until 1854, subject to the authority of the board of control; 3, India was thrown open to the independent enterprise of British subjects; 4, all the property, real and personal, in possession of the company on April 22, 1834, was vested in the crown, and was to be held and managed by the company in trust for the crown, the stockholders being assured by government an annual dividend of $10\frac{1}{2}$ per cent. on the stock; 5, of the treasure of the company, valued in 1834 at £21,103,000, £2,000,000 were formed into a sinking fund, with the proceeds of which, in or after 1874, to buy out the stockholders at 200 per cent. valuation, £8,423,000 were consumed in the payment of the company's debts, and the balance was appropriated to various improvements in India; 6, the stock might be bought in by parliament at the rate of £200 for £100 at any time after 1874, with the further condition that if at any time after 1854 the company were deprived by parliament of the government of India, stockholders might demand of parliament to purchase their stock, after three years' notice given. When in 1854 the last charter of the company expired, it was determined by act of parliament to renew it, but not for any given time.—The capital stock, originally £2,000,000, had been increased at various times, till in 1793 it amounted, to £6,000,000. At this it remained by law. This stock was owned in 1835 by 3,579 persons. As it was marketable, of course the number of stockholders continually changed. The ownership of stock to the amount of £1,000 (worth in 1835 £2,540) gave the privilege of one vote at the stockholders' meetings. The owner of £3,000 had two votes, of £6,000 three, of £10,000 and over, four. Women as well as men, and foreigners as well as Britons, if owning the requisite amount of stock, and present in London in person or by proxy, had the privilege of debating and voting. Stock must, however, have been held 12 months before the owner was entitled to a vote. In 1852 there were 2,583 voters, of whom 372 were women, 20 were peers of the realm, 10 members of parliament, 50 ex-directors, 86 clergymen, 19 physicians, 222 army officers, and 28

naval officers. Before 1836 the majority of the stockholders were merchants and bankers, but the changes in the constitution, which extinguished the company as a trading association, caused a material decrease of this class. The court of directors was originally composed of 24 stockholders, qualified by the ownership of at least £2,000 of stock. By the act of 1853 the court consisted of 18 members, of whom 12 were elected by the stockholders, and 6 were chosen by the crown from men who had served in India. For expediting business, the members were annually divided into three committees: one on finance, and interior and marine interests connected therewith; the second on politics and war; and the third on the judicial and legislative interests. The most important part of the court of directors, however, was the secret committee. To this, composed of the chairman, deputy chairman, and the senior director, were referred all confidential communications between the board of control and the court. The despatches of the board as to political matters were transmitted through the secret committee, and might be sent on by them without being submitted to the court. The chief privilege of directorship was that of making appointments; the directors filled all vacancies, not only in the English branch of the company's service, but in all the subordinate functions in India. The board of control, the governing power in the company, consisted at first of six members, but afterward the sovereign had the privilege of appointing a suitable number, of whom the lord president of the council, the lord privy seal, the first lord of the treasury, the two principal secretaries of state, and the chancellor of the exchequer must form part. The powers of the board increased until long before its abolition in 1858 it had become a court from whose decisions there was no appeal.—The expense of the company's military force in the East Indies in 1856 was £10,229,584. The debts of the Indian government in England on May 1, 1857, amounted to £9,377,401, and the credits to £5,488,467, leaving a surplus of debts of £3,888,934. The Indian revolt of 1857-'8 called public attention more forcibly than at any previous period to the management of Indian affairs by the company, and led to the passing (Aug. 2, 1858) of the act "for the better government of India," by which "all the territories heretofore under the government of the East India company are vested in the British queen, and all its powers are to be exercised in her name, one of the principal secretaries of state to have all the powers hitherto exercised by the company or by the board of control. The military and naval forces of the East India company are to be deemed the forces of the queen, and all persons holding any office, employment, or commission in India are transferred to the service of the crown. All functions and powers of the courts of directors and proprietors are to cease, to-

gether with the salaries paid, and the board of control is likewise abolished." This act, although depriving the East India company of all its power and importance, did not abolish it, and provided for the manner in which the directors should thereafter be appointed; but its functions are by it almost exclusively confined to the administration of the stock and the distribution of the fixed interest or dividends upon the old share capital of the company.

EAST INDIES, a vague geographical term applied to southern Asia east of the Indus, and to the adjacent islands. (See **INDIA**.) The name India was unknown to the earlier Greeks, and the later ones used it to signify an indefinite extent of country lying beyond the Indus, of which they had a very imperfect knowledge. The modern Europeans applied it in much the same way until after the discovery of America. Columbus supposed that he had reached India by sailing westward, and the lands discovered, by him and the other Spanish navigators in the western hemisphere were for a time collectively known as India. The king of Spain assumed the title of king of the Indies, and the council for the colonies was styled the supreme council of the Indies. When the mistake was discovered, the distinctive term West Indies was applied to America, and that of East Indies to Asiatic India. In process of time the term West Indies became restricted to the islands lying between North and South America, and the term India to the two peninsulas of Hither and Further India. The latter country is also called Chin-India or Indo-China, and in its most restricted sense the term India now includes only the western of the two peninsulas, or Hindostan in the wider sense. The term East Indies, as vaguely and popularly used, comprises Hindostan, Burmah, Siam, Laos, Anam, Malacca, Ceylon, Sumatra, Java, Borneo, Celebes, the Sunda and Banda islands, the Moluccas, the Philippines, and the rest of that vast archipelago, and is sometimes extended even to China and Japan.

EASTLAKE, Sir Charles Lock, an English painter, born in Plymouth in 1793, died in Pisa, Italy, Dec. 23, 1865. He commenced the study of art at the royal academy, under the direction of Fuseli, and continued it at the Louvre in Paris. He was compelled to leave France by the return of Napoleon from Elba, of whom he painted soon after a portrait, as he appeared at Plymouth on board the *Bellevue* on his way to St. Helena. In 1817 he went to Rome, and remained there for many years, with the exception of visits to Greece, Sicily, &c. Among his most celebrated paintings are one in illustration of a passage in Byron's "Dream," "Christ weeping over Jerusalem," "Escape of Francesco di Carrara," "Pilgrims arriving in sight of Rome," "Christ blessing little Children," "Hagar and Ishmael," and the "Raising of Jairus' daughter." In 1841 he was appointed secretary to the royal commission on fine arts; from 1843 to

1847 he was keeper of the national gallery; and in 1850 he was knighted, made president of the royal academy, and director of the national gallery. He was the author of notes to Kugler's "Handbook of Painting," which was translated by Lady Eastlake, and of "Materials for a History of Oil Painting."—Lady Eastlake, whom he married in 1849, had acquired before her marriage, while Miss Elizabeth Rigby, literary reputation by the publication of "Letters from the Shores of the Baltic" (1841), "Livonian Tales" (1846), and other writings. She is also an artist of considerable ability. Eastlake's life was published by Lady Eastlake (London, 1870), who also edited his posthumous "Contributions to the Literature of the Fine Arts."

EASTLAND, a N. W. county of Texas intersected by Leon river; area, 900 sq. m.; pop. in 1870, 88. The central portion is hilly, the E. part is covered with post oak, &c., and some fertile prairies exist in the west. In 1870 there were 14,041 cattle.

EAST LIVERPOOL, a village of Columbiana co., Ohio, on the right bank of the Ohio river, and on the Cleveland and Pittsburgh railroad, about 35 m. N. W. of Pittsburgh; pop. in 1870, 2,105. It is famous for its potteries. The manufacture of china and parian ware has been recently commenced. It contains 16 manufactories of earthen ware, 2 of red brick, 2 of terra cotta, 1 of barrels, 2 flour mills, 2 planing mills, an iron foundery, 2 weekly newspapers, and several schools and churches.

EASTMAN, Charles Gamage, an American poet, born in Fryeburg, Me., June 1, 1816, died in Burlington, Vt., in 1861. He early went with his parents to Barnard, Vt.; was editor of the Burlington "Sentinel" in 1835-'6; commenced the "Lamoille River Express" newspaper at Johnson, Vt., in 1838; established the "Spirit of the Age" at Woodstock, Vt., in 1840; and purchased the "Vermont Patriot" and removed to Montpelier in 1846. He was postmaster at Woodstock and Montpelier for several years, and senator for Washington county in 1851-'2. He published a volume of poems in 1848, was a contributor of poetry to reviews and magazines, and pronounced poems at the university of Vermont, and at Dartmouth and other colleges.

EASTMAN, Mary Henderson, an American authoress, born in Warrenton, Fauquier co., Va., about 1817. In 1835 she married Capt. Seth Eastman of the U. S. army (author of a "Treatise on Topographical Drawing," and of the illustrations to national publications on the Indians, 1850-'57), with whom she resided for many years at Fort Snelling, Min., and at other frontier stations. She has published "Dacotah, or Life and Legends of the Sioux" (New York, 1849); "Romance of Indian Life" (Philadelphia, 1852); "Aunt Phillis's Cabin," a reply to Mrs. Stowe's "Uncle Tom's Cabin" (1852); "American Aboriginal Portfolio"

(1853); and "Chicora and other Regions of the Conquerors and the Conquered" (1854).

EAST NEW YORK, a post village of the town of New Lotts, Kings co., New York, joining the S. E. extremity of Brooklyn; pop. about 5,000. It is built on elevated land, fanned by the sea breezes, and is very healthy. Most of the residents are employed in New York or Brooklyn. Cypress Hills cemetery and the cemetery of the Evergreens are near its borders. The village is at the terminus of a branch of the Long Island railroad from Jamaica, and is connected by horse cars with the Brooklyn ferries. It contains a few manufactories, several schools, two weekly newspapers, and five churches. An unsuccessful attempt was made in 1873 to annex it, with the rest of Kings co., to Brooklyn.

EASTON, a borough, and the capital of Northampton co., Pennsylvania, on the right bank of the Delaware river, between the mouths of the Lehigh river and Bushkill creek, opposite Phillipsburg, N. J., and 54 m. N. of Philadelphia; pop. in 1850, 7,250; in 1860, 8,944; in 1870, 10,987. Excepting the eastern part of the town, the site is hilly, but the plot is nevertheless very regular, and the streets are wide and at right angles. The town has a public square, is lighted with gas, and supplied with water from the Lehigh river. The height of reservoirs on the surrounding hills is so great that a large portion of the town fires are extinguished without the aid of engines. A handsome cemetery of 40 acres has been laid out on picturesque and broken ground overhanging the Bushkill creek. There is a farmers' and mechanics' institute, whose buildings and grounds cover 30 acres, where fairs are annually held. The rivers are each spanned by several bridges, and the town is connected with the anthracite region, and with New York, Philadelphia, and the west, by means of the Lehigh, the Morris, and the Delaware canals, and the Lehigh Valley, the Lehigh and Susquehanna, the Central New Jersey, the Morris and Essex, the Belvidere Delaware, and the Delaware, Lackawanna, and Western railroads. Being the outlet of a rich agricultural region, Easton formerly manufactured and exported a large amount of agricultural products. The surrounding country contains inexhaustible deposits of the best iron ore, which is largely manufactured here; and within 12 miles are found large deposits of the best zinc ore, which is manufactured near the mines. The borough contains 3 lager-beer breweries and 4 bottling establishments, 3 tanneries, extensive paint works, 3 carriage factories, 3 machine shops and founderies, 3 manufactories of cabinet ware, a pottery, 2 sash and blind factories, an extensive rope walk, an oil refinery, and 3 banks, with an aggregate capital of \$987,600. In South Easton, a borough on the opposite bank of the Lehigh (pop. in 1870, 3,167), are a cotton factory, a blast furnace, a large wire and

rolling mill, and the machine shops of the Lehigh Valley railroad. Easton is the seat of Lafayette college (Presbyterian), organized in 1831, which in 1872 had 25 professors and instructors, 259 students, and a library of 9,000 volumes. A scientific department was organized in 1865. There are 35 public schools, with 90 teachers. The Easton library association has 6,000 volumes. There are 2 daily and 4 weekly newspapers, a free reading room, and 14 churches.—The borough was laid out in 1738 and incorporated in 1789. The Six Nations and seven other Indian tribes met here in council in 1758 with the governors of Pennsylvania and New Jersey and Sir William Johnston. Gen. Washington made it in the revolution a rendezvous for numbers of British prisoners.

EASTPORT, a town of Washington co., Maine, and the port of entry of Passamaquoddy district, situated on the boundary line between the United States and New Brunswick, about 90 m. E. of Bangor; pop. in 1870, 3,736. Its area is little more than 3 sq. m., comprising Moose island and several smaller islands in Passamaquoddy bay. It was incorporated in 1798. The village is compactly built on the S. E. shore of Moose island, and communicates with the mainland by a covered bridge 1,200 ft. long to Perry, and by ferries to Lubec and other places. The town has a spacious harbor, in which the tides rise more than 25 ft., and which is never blocked up by ice. In the season of navigation regular lines of steamers run up the river St. Croix to St. Andrew's and Calais, and also to Boston, Portland, and St. John, N. B. The harbor is defended by Fort Sullivan, which stands on a hill in the midst of the village. The custom house is a fine building of brick and stone, erected in 1850 at a cost of \$36,500. The trade with the neighboring British provinces is large, and lumber is exported in considerable quantities. Eastport is also the seat of a considerable fishing business. Large quantities of herring are taken in weirs about the shores of the bay. The value of imports from foreign countries for the year ending June 30, 1872, was \$933,536; exports to foreign ports, \$1,036,350. The town contains a national bank, a savings institution, a fire insurance company, a weekly newspaper, six school houses, which have an average attendance of about 450 pupils, and seven churches.—Eastport was captured by a British force July 11, 1814. It was claimed as included in the original limits of the province of New Brunswick, and the British commissioners at Ghent refused to agree to the surrender of the island in Passamaquoddy bay. The matter was referred to another commission, and on June 30, 1818, the place was surrendered to the United States. During the four years of military occupation it was governed by martial law.

EAST RIVER, a strait connecting New York bay with Long Island sound, about 18 m. long,

and between New York and Brooklyn about three fourths of a mile wide. It leaves the sound at a point called Throg's neck, where there is a lighthouse with a fixed light, and where Fort Schuyler defends the N. E. approach to New York; and it enters the bay S. E. of Manhattan island, between the metropolis and Brooklyn. It also communicates with the Hudson by a narrow channel called Harlem river and Spuyten Duyvel creek, which separate Manhattan island from the mainland. It has a rapid current caused by the tide from the Atlantic, which, gathering force as it flows W. into the narrowest part of the sound, reaches its greatest height in the East river, arrives at New York three quarters of an hour earlier than that which rises in the bay, and drives upward along the E. shore of the Hudson many miles in advance of the tide on the W. shore. The East river is navigable by vessels of the largest size, and is crossed by numerous steam ferries. It contains several islands, and has a pass called Hellgate, 7 m. from New York bay, the navigation of which is attended with considerable danger; but extensive blasting operations are now (1874) in progress at the expense of the United States government to remove all the obstacles to navigation. (See **BLASTING**.)

EAST RIVER BRIDGE. See **BRIDGE**, and **BROOKLYN**.

EAST SAGINAW, a city of Saginaw co., Michigan, on the E. bank of Saginaw river, about 16 m. above the bay of the same name, opposite and a little below the city of Saginaw, 57 m. N. N. E. of Lansing, and 90 m. N. N. W. of Detroit; pop. in 1860, 3,001; in 1870, 11,350, of whom 5,066 were foreigners. The city extends along the river, nearly N. and S., about 3 m., and is built up for about a mile back. The business portions are constructed chiefly of brick, and several of the schools and churches are handsome edifices. Three swing bridges cross the Saginaw at this point, and there are two street railroads. The Flint and Père Marquette railroad passes through the city, from which radiate a branch to Bay City and another (in progress) to Caro, Tuscola co. It is also the terminus of the Saginaw Valley and St. Louis railroad, while the Jackson, Lansing, and Saginaw line runs along the opposite bank of the river. It is the principal depot of the lumber and salt trade of the Saginaw valley, and is largely engaged in furnishing provisions and supplies to the lumber regions in the vicinity. It contains 5 founderies and machine shops, 2 boiler shops, 5 saw mills, a shingle and stove mill, and 4 salt manufactories, producing 102,752 barrels of salt in 1872. There are also several shingle and saw mills on the opposite side of the river. The car and repair shops of the Flint and Père Marquette railroad employ about 500 men. There are 3 national banks, with an aggregate capital of \$500,000, and a savings bank, with \$100,000 capital. The city is divided into six

wards, and has more than a mile of paved streets, and an extensive system of sewers in progress. Water works are also in process of construction. An excellent system of public schools is in operation, embracing in 1872 1 high, 8 grammar, and 22 primary schools, with 34 teachers and 1,628 pupils. The expenditures for school purposes during the year were \$46,375, of which \$20,350 were for permanent improvements, and \$15,859 for teachers' wages. There are 2 daily and 4 weekly (1 German) newspapers, and 10 churches.—East Saginaw was laid out in 1850; about 1855 it was incorporated as a village, and in 1859 a city charter was granted.

EATON, a S. county of Michigan, intersected by Grand river; area, 576 sq. m.; pop. in 1870, 25,171. The surface is undulating. In the N. and middle part are forests, and in the S. plains with scattered trees. The soil is productive. The Peninsula railroad and the Grand River Valley division of the Michigan Central railroad pass through it. The chief productions in 1870 were 326,377 bushels of wheat, 231,955 of Indian corn, 300,308 of oats, 16,876 of barley, 177,313 of potatoes, 31,212 tons of hay, 749,464 lbs. of butter, 221,732 of wool, 204,028 of maple sugar, and 213,611 of hops. There were 5,526 horses, 6,423 milch cows, 8,932 other cattle, 49,733 sheep, and 10,243 swine; 6 manufactories of agricultural implements, 9 of carriages and wagons, 5 of furniture, 5 of iron castings, 5 of saddlery and harness, 3 of sashes, doors, and blinds, 4 flour mills, 4 planing mills, 36 saw mills, 1 wool-carding and cloth-dressing, and 5 wood-turning and carving establishments. Capital, Charlotte.

EATON, Amos, an American physicist, born in Chatham, N. Y., May 17, 1776, died in Troy, May 6, 1842. He was early employed as a surveyor, graduated at Williams college in 1799, was admitted to the bar in 1802, and settled in Catskill as a lawyer and land agent. For several years he devoted his leisure to the study of the natural sciences, in 1810 delivered at Catskill a popular course of lectures on botany, and in 1817 he lectured at Williams college on chemistry, geology, and mineralogy. His lectures were repeated in several New England towns and cities, and in 1818, by the invitation of Gov. Clinton, before the legislature of New York. While in Albany he made suggestions which ultimately resulted in the publication of "The Natural History of New York." In 1820–21, in connection with Drs. T. Romeyn Beck and Lewis C. Beck, and at the expense of Stephen Van Rensselaer, he made geological and agricultural surveys of Albany and Rensselaer counties, the beginning of such surveys in the United States, reports of which were published. In 1820 he was made professor of natural history in the medical college at Castleton, Vt. Van Rensselaer subsequently employed him to make a geological survey of the district adjoining

the Erie canal, and the result was published in 1824, together with a profile section of rock formations from the Atlantic ocean across Massachusetts and New York to Lake Erie. In 1824 the Rensselaer school of science (now polytechnic institute) was established at Troy, and Eaton was placed at its head as senior professor. His works, of which several editions have been published, are: "Elementary Treatise on Botany" (1810); "Manual of Botany" (1817); "Botanical Dictionary" (1817); "Botanical Exercises" (1820); "Botanical Grammar and Dictionary" (1828); "Chemical Note Book" (1821); "Chemical Instructor" (1822); "Zoological Syllabus" (1822); "Cuvier's Grand Division" (1822); "Philosophical Instructor" (1824); "Directions for Surveying and Engineering" (1838); "Geological Text Book" (1830); "Geological Note Book" (1841); and extended reports of several geological and agricultural surveys.

EATON, George W., an American clergyman and educator, born near Huntingdon, Pa., July 3, 1804, died at Hamilton, N. Y., Aug. 3, 1872. He graduated at Union college in 1829, and was appointed a tutor. From 1831 to 1833 he was professor of ancient languages in Georgetown college, Ky. In 1833 he became connected with the Hamilton literary and theological institution (Baptist), incorporated in 1846 as Madison university, where he was successively professor of mathematics and natural philosophy, of civil and ecclesiastical history, and of systematic theology. He was president of the university from 1856 to 1868, and president of the theological seminary and professor of homiletics from 1861 to 1871.

EATON, William, an American soldier, born in Woodstock, Conn., Feb. 23, 1764, died in Brimfield, Mass., June 1, 1811. At the age of 16 he enlisted in the revolutionary army, from which he was discharged in 1783. In 1790 he graduated at Dartmouth college, and two years later received a captain's commission in the army. In the summer of 1797 he was appointed American consul at Tunis, arrived there in March, 1799, and for several years was engaged in a series of negotiations and altercations with the bey, having reference to the annual payment of tribute money. In this he acted with a boldness and tact which secured to the commerce of his country an immunity from the attacks of Tunisian cruisers. In 1803 he returned to the United States, received the appointment of navy agent of the United States for the Barbary states, and accompanied the American fleet to the Mediterranean in the summer of 1804. Learning that Hamet Caramelli, rightful bey of Tripoli, with which the United States were then at war, had taken refuge in Egypt, he sought him out, and in the early part of 1805 assisted him in assembling a force of about 500 men, four fifths of whom were Arabs, the remainder being Christian adventurers, principally Greeks, with nine Americans. Having secured the coöperation of the

American fleet, the little army, under the command of Eaton, took up its march across the Libyan desert for Derne, the capital of the richest province of Tripoli, a distance of about 600 miles. On several occasions the mutinous disposition of the Arab sheiks and the irresolution of Hamet imperilled the safety of the handful of Christians belonging to the expedition; but the forces were brought in safety to Bomba, on the coast, where the American ships Argus and Hornet were in waiting. On April 27, with the assistance of the ships of war, Eaton attacked and carried Derne after a furious assault, in which he was wounded. A few days later an army of several thousand Tripolitans, despatched by the reigning bey, approached the town, and for several weeks occasional sharp skirmishes took place between the opposing forces, Eaton's army having meanwhile been considerably augmented. On June 11 a general engagement was fought, and the enemy was totally routed and driven back to the mountains. At this moment, when Eaton was preparing by a rapid march to fall upon Tripoli, reinstate Hamet on the throne, and release the American captives detained there without ransom, intelligence arrived that a peace had been concluded by Col. Tobias Lear, the American consul general at Algiers, one of the conditions of which was that \$60,000 should be paid the bey for the ransom of the Americans. Eaton soon after returned to the United States, where he received many marks of popular favor, the legislature of Massachusetts voting him 10,000 acres of land. The remainder of his life was passed in Brimfield, Mass., which town he at one time represented in the state legislature. A memoir of him was published in Brookfield, Mass., in 1813; and another, by C. C. Felton, is contained in Sparks's "American Biography."

EAU CLAIRE, a W. county of Wisconsin, intersected by Chippewa and Eau Claire rivers; area, 648 sq. m.; pop. in 1870, 10,769. The surface is uneven, and the soil fertile. The West Wisconsin division of the Milwaukee and St. Paul railroad passes through it. The chief productions in 1870 were 205,827 bushels of wheat, 69,964 of Indian corn, 294,493 of oats, 18,336 of barley, 29,011 of potatoes, 5,760 tons of hay, and 124,365 lbs. of butter. There were 1,458 horses, 1,834 milch cows, 2,509 other cattle, 1,864 sheep, and 1,839 swine; 7 manufacturing of carriages and wagons, 4 of furniture, 3 of iron castings, 2 of machinery, 4 of sashes, doors, and blinds, 5 of bricks, 3 flour mills, 23 saw mills, and 4 breweries. Capital, Eau Claire.

EAU DE COLOGNE, or *Cologne Water*, alcohol perfumed with essential oils, named from the city of Cologne, in which its manufacture is extensively prosecuted, and from which several million bottles are annually exported. It was first made at Cologne in the 17th century by an Italian named Feminis, and after him, there as well as in Italy, by an Italian family

named Farina, the most famous of whom was Giovanni Maria Farina, who succeeded to the business in 1709. His name is now adopted by several of the manufacturers of Cologne, and in other countries it is attached to very different preparations, resembling the genuine only in the bottles and labels. Numerous recipes are given for this preparation, most of which are very complicated from the great number of ingredients. Purity of the volatile oils, and also of the alcohol, and freedom especially of the latter from fusel oil, are essential to the perfection of the perfume. It is also important that no one of the volatile oils should so predominate that its odor may be perceived above the rest. Distillation after mixing is recommended in some cases, and in others contemned, as the volatile oils do not distil over so readily as the spirit. When not distilled, the mixtures should stand for some weeks or months, that the oils may be thoroughly dissolved in the alcohol. The following is given as the process of Farina in the *Dictionnaire des arts et manufactures*: balm and mint of Notre Dame, each 350 grams; petals of roses and violets, each 120; lavender flowers, 60; absinth (wormwood), 30; sage and thyme, each 30; orange flowers, nutmegs, mace, cloves, and cinnamon, each 15; camphor and angelica root, each 8. These ingredients are digested in 660 lbs. avoirdupois of rectified alcohol for 24 hours, adding two lemons and two oranges cut into slices. The mixture is then distilled by heat of the sand bath until 440 lbs. have passed over. To this product are then added essences of lemon, of cedrat, of balm, and of lavender, each 45 grams; essences of neroli and of rosemary, each 15; essence of jasmine, 30; essence of bergamot, 350. The whole are thoroughly mixed and then filtered. It is also prepared without distillation, but the odor is never so fine. Several recipes are published for imitations which may be more cheaply prepared.

EAU DE LUCE (*aqua lucie*), a liquid soap made by mixing a little oil of amber and mastic or balm of Gilead with ammonia. It is a remedy for the bites of poisonous animals. The compound tincture of ammonia is substituted for it, made by dissolving 2 drachms of mastic in 9 fluid drachms of rectified spirit, pouring off, and adding a pint of strong ammonia, and 14 minims of oil of lavender.

EBAL AND GERIZIM, two mountains in Palestine, within 200 paces of each other, and separated by a deep valley, in which stood the old city of Shechem, now Nablus. They are much alike, being semicircular, about half a league long, and on the sides nearest Shechem nearly perpendicular. Ebal is 1,028 ft. above Nablus and 2,700 ft. above the sea; Gerizim about 100 ft. lower. They were made memorable by the solemn ratification of God's covenant with the Jews after they had passed over Jordan, when six tribes were placed on Gerizim and six on Ebal, the former to pronounce blessings on

those who should faithfully keep the divine law, and the latter to pronounce curses on those who should violate it; whence Gerizim was known as the mount of blessing and Ebal as the mount of cursing. According to the injunction of Moses, the Jews after obtaining possession of Canaan built an altar and celebrated a feast on Ebal. The Samaritans contended that this should have been done on Gerizim, and they built a temple on the latter, the ruins of which are still visible, and regarded it as the Jews regarded their temple at Jerusalem. They also held that Gerizim was the mountain upon which Abraham was directed to offer up Isaac. The remark of the Samaritan woman to Christ at Shechem (John iv. 20) is in allusion to this difference of opinion as to the proper place of worship. The Samaritans still have an annual sacrifice on Mt. Gerizim.

EBELING, Christoph Daniel, a German scholar, born near Hildesheim, Hanover, in 1741, died in Hamburg, June 30, 1817. He was noted for his extensive knowledge of oriental languages, of classic and foreign literature, and of history and geography. One of his publications was a history and geography of North America (7 vols., Hamburg, 1796-1816), forming a continuation of Büsching's general geography, for which he received a vote of thanks from the United States congress. He paid special attention to the geography of the new world, and collected about 10,000 maps and nearly 4,000 books, all relating to America. This library is now in Harvard college.

EBENEZER, the name of a place where the Israelites were defeated when the ark of God was taken (1 Sam. iv. 1), and also of a memorial stone or monument set up by Samuel to commemorate their victory over the Philistines at Mizpeh, when God interposed for their deliverance (1 Sam. vii. 5-12). The compound word signifies the stone of help. The monument was erected by the prophet, saying, "Hitherto hath the Lord helped us." The name of the place, though mentioned first, was probably of later use, being borrowed from that of the monument.

EBERHARD IM BART (Eberhard with the beard), the first duke of Württemberg, born Dec. 11, 1445, died Feb. 14, 1496. His father, Count Louis the Elder, dying while he was young, his education was neglected. Before he was 14 he wrested the government from his uncle Ulrich, who had been appointed regent. A pilgrimage to the Holy Land, and the influence of his wife, the princess Barbara of Mantua, had a happy effect upon his character. He became celebrated in German history as the founder of the undivided sovereignty and of the representative constitution of Württemberg. He devoted himself to study, promoted science and literature, and founded in 1477 the university of Tübingen. He improved the laws and the condition of the convents in his country, and was a friend of peace. The emperor Maximilian of Germany, who conferred

on him the title of duke (1495), declared at his grave several years afterward: "Here lies a prince who has left no equal in the German empire in princely virtues, and whose advice I have frequently followed with advantage."

EBERHARD, Johann August, a German philosopher, born in Halberstadt, Aug. 31, 1739, died Jan. 6, 1809. He was first a teacher, and then a pastor. In a work entitled *Neue Apologie des Sokrates* (3d ed., Berlin, 1788), he opposed the opinion which had been lately advanced that the virtues of the pagans were only splendid vices. A religious romance entitled *Amyntor* did not, as it was designed to do, cause the bold assertions of this apology to be forgotten. In 1778 he was appointed professor of philosophy in the university of Halle, and soon after a member of the academy of Berlin. He was attached to the philosophy of Leibnitz and Wolf, and combated the systems of Kant and Fichte. His writings on philosophical and æsthetical subjects are numerous.

EBERHARD, Konrad, a German sculptor and painter, born at Hindelang, Bavaria, Nov. 25, 1768, died in Munich, March 13, 1859. He studied at Munich and Rome, and in 1816 became professor of sculpture in the academy of fine arts at Munich. He painted many pictures illustrating the conflicts, progress, and triumphs of the Christian religion. Among his best works are the tomb of the princess Caroline in the *Theatinerkirche*, and the statues of St. George and St. Michael before the Isar gate in Munich.

EBERS, Georg Moritz, a German Egyptologist, born in Berlin, March 1, 1837. He studied at Göttingen and Berlin, and taught for several years at the university of Jena. After a visit to Egypt, Nubia, and Arabia, he received in 1870 a professorship at Leipsic. His first publication, *Eine ägyptische Königstochter* (3 vols., Stuttgart, 1864), which describes the subjugation of Egypt by the Persians in the style of a historical novel, has passed through numerous editions, and was translated in Holland, England, and America (New York, 1871). His subsequent works are more scientific; the most important are *Aegypten und die Bücher Mose's* (1st vol., Leipsic, 1868) and *Durch Gosen zum Sinai* (1872).

EBIONITES (Heb. *ebyonim*, poor people), a party in the early Christian church. The name was first assumed by such Christians as held to Jewish opinions and practices. After the Christianity which savored of Judaism had come to be regarded by the church as a heresy, the name, in its Greek form, was applied to the members of the party by their opponents, and they themselves adopted that of Nazarenes. The doctrine of the Ebionites was a mixture of Judaism and Christianity. While they accepted the Old Testament in its integrity, they rejected the New Testament, substituting a gospel based upon the facts in the Gospel of Matthew. This was known to the primitive Christians as the "Gospel of the Hebrews."

The Ebionites denied the divinity of Christ, retained the practice of circumcision while observing the rites of baptism and the Lord's supper, kept the seventh day of the week, and conformed in many things to the ascetic discipline of the Essenes. Their opinions were afterward somewhat modified, and they were divided particularly in their dogma concerning the birth of Jesus and the method of his union with God. As Epiphanius represents them, they believed that Jesus was the incarnation of an exalted superangelic spirit, who came to republish the law which Moses had published before, and which was the law of right and truth given to the original Adam. They were opposed to the doctrine of priestly and monastic celibacy. They interpreted literally the Hebrew prophecies in regard to the Messiah's kingdom, and expected that material reign of Christ which Isaiah describes. Ebionites were found in Palestine and Syria down to the end of the 4th century. They began about that time to come into frequent collision with the Catholics, and soon disappeared from history.

EBN. See BEN.

EBOLI, Anna de Mendoza, princess of, a Spanish lady of the 16th century, daughter of a viceroy of Peru. At an early age she was introduced at the court of Philip II. by her husband the prince of Eboli, a favorite of the king and preceptor of his son Don Carlos. Though one of her eyes was defective, her beauty attracted general attention, and she became noted for her amorous as well as political intrigues. Among her admirers were the king and his secretary of foreign affairs, Antonio Perez. She was implicated in the assassination of Escovedo, the envoy of Don John of Austria.

EBONY (*diospyros ebenum*, Willdenow), a tree with hard, heavy wood, native of the East Indies. The black ebony, the most highly prized, grows spontaneously in Ceylon, Madagascar, and Mauritius. There are other colors, such as green, red, yellow, and white and black striped. There is another kind called ironwood from its intense hardness. The heart wood of *D. reticulata*, a lofty tree in Mauritius, is also esteemed. The ebony of the Comandel coast is derived from *D. melanoxylon* (Roxburgh). Ebony is likewise procured from *D. tomentosa* and *D. Roylei* of the East Indies. The fruit of many of the ebony trees is considered edible by the natives, although it is generally astringent. The famous oblivion-producing fruit of the lotus is supposed to be that of *D. lotus* of Africa. The date plum and persimmon are representatives of this genus.

EBRO, a river of Spain, the Iberus of the Romans, which gave the name of Iberia to the country it waters. It rises in the mountains on the N. border of Spain, in the province of Santander, and flows S. E. at first between lofty and picturesque heights, separating Álava and Navarre from Old Castile, intersecting Aragon near its centre, and after a course of about 400 m. emptying into the Mediterranean through

a double embouchure at Cape Tortosa, near the S. extremity of Catalonia, in lat. 40° 42' N. At Mequinenza it passes through a defile where once was probably a barrier restraining its waters as a lake in the country of Aragon. Its principal tributaries are the Aragon, Gallego, and Segre, on the left or N. side, and the Oca, Jalon, and Guadalupe, on the right or S. It abounds with shoals and rapids, but boats may pass with difficulty as high as Tudela in Navarre. A canal has been cut parallel with its bank from Tudela to Sastago, about 40 m. below Saragossa. Improvements have also been made in the bed of the river lower down, and from a point near Amposta the San Carlos canal has been opened southerly across the delta to the harbor of Los Alfaques. The principal traffic is the transport of grain, and the floating of timber from the northern forests. The Ebro was the boundary between the possessions of Rome and Carthage, and afterward between those of Charlemagne and the Moors.

ÉCARTE, a game of cards, played by two persons with a piquet pack, or pack from which the twos, threes, fours, fives, and sixes have been taken, leaving 32 cards. These rank as follows: the king is the highest card, and queen, knave, ace, ten, nine, eight, and seven follow in succession, the only peculiar feature being the position of the ace below the court cards and above the rest. The pack having been shuffled as usual (the deal belonging to the player cutting the highest card by whist rules), five cards are dealt to each person, two and three or three and two at a time, as in the American game of euchre. The eleventh card is turned as in that game, and determines the trump, the rest of the pack being called the talon. If the non-dealer is satisfied with the hand he holds, he now plays, first naming the suit he intends leading. If his adversary has a higher card of the suit led, he is obliged to take the trick; but he is not obliged to trump, though of course permitted to do so. The holder of the king of trumps must declare, before playing at all, that he has it, by saying "I have the king." If he leads the king, he may declare it just after putting it down, but before it is covered by his adversary's card, else he cannot score it in that hand, *i. e.*, he cannot count the one point to which his holding or turning up the king would otherwise entitle him. The winning three tricks also counts one point; the winning all (called having the vole) counts two; five points make game. If the non-dealer, contrary to what has been thus far assumed, is not satisfied with the cards dealt to him, he says, before playing, "I propose;" and the dealer, if he also wishes other cards, assents. The non-dealer then throws aside such cards as he wishes to reject (called the discard), and the dealer gives him, from the top of the talon, a corresponding number to take their place. The dealer also exchanges his own cards in the same manner; but both must discard before the fresh cards

are seen. If both the players agree, they may continue discarding, and so changing their hands, until the talon is exhausted; but one cannot keep on after the other is satisfied; and if it is found, after several discards, that too few cards remain in the talon to supply the number required, this must be made up from the cards last discarded. If the dealer will not consent to allow his adversary an exchange after the first deal, he is obliged to win three tricks, or if he fails loses two points; and if the non-dealer plays without requesting a discard, he is subject to the same conditions. If either party looks at the discards, he must as penalty play all the rest of the game with his cards exposed to his opponent's view. If the dealer turn up a trump by mistake in dealing cards for the discard, he is not permitted to refuse his adversary an exchange of cards during that hand. The general rules concerning mistakes, misdeals, &c., are the same as in similar games at cards.—Écarté had its origin in Paris, and derives its name from the French verb *écarter*, to discard.

ECBATANA, an ancient city, capital of the Median empire, and the favorite summer residence of the kings of Persia. Its foundation was attributed to Semiramis; but Herodotus makes Deioeces its founder, and describes particularly its position on a conical hill, and its enclosure by seven concentric walls, each inner one being higher than the next outer one, which were painted with different colors, the innermost wall being gilded, and the next plated with silver. An account of the building of the city by Artaphaxad is given in the book of Judith, and it is mentioned by Ezra under the name of Achmetha. It is probable that this city was founded and flourished subsequently to Babylon and Nineveh, and that it occupied the position ascribed to it by Diodorus and others, near the site of the modern city of Hamadan. Its citadel was of enormous strength, and adjoining it was the royal palace, rivalling the noblest edifices of the East. The fragrant cedar and the cypress were the only kinds of wood that entered into its construction, and its columns, beams, and ceilings were covered with golden and silver plates. Its splendid architecture and spacious apartments, its fountains and gardens, and the mild climate of the place, attracted to it, even after the fall of the Median empire, the sovereigns of Persia, to repose during the summer months. Darius fled from his defeat at Arbela to Ecbatana, and Alexander the Great, having become master of the town, bore away a rich booty. Under the Seleucidæ its edifices and palaces were plundered, and its ramparts began to crumble away. It subsequently fell to the Parthians, and was the frequent residence of their kings; but its ruin was completed amid the revolutions which preceded the establishment of the new Persian empire. Of its former magnificence only a few broken columns, cuneiform inscriptions, medals, and fragments of sculpture, dug from the

earth in the vicinity of Hamadan, now remain. (See HAMADAN.)

ECCHELLENSIS, or *Echellensis*, Abraham, a learned Maronite, professor of the Syriac and Arabic languages in Paris and in Rome, born at Ekkel, Syria, died in Italy in 1664. He was educated at Rome, and took the degree of doctor of theology and of philosophy. In 1630 he was invited to Paris to assist in editing the polyglot Bible of Le Jay. He contributed to this work the book of Ruth in Syriac and Arabic, and the third book of Maccabees in the latter language. He was besides the author of several historical writings and translations from the Arabic. In 1642 he returned to Rome as professor of the oriental languages.

ECCLESIA (Gr. ἐκκλησία, from ἐκκαλεῖν, to call out or summon), in ancient Athens, a general assembly of the citizens summoned together to discuss and decide matters of public interest. The ordinary assemblies were held three times monthly on established days; the extraordinary were specially convened on any sudden and pressing emergency. When the occasion was of extreme importance, special messengers were despatched into the country to summon the people, and the assembly thus convened was termed a cataclesia. These assemblies were originally held in the Agora; but during the most flourishing periods of Athens, in the times of Themistocles, Pericles, and Demosthenes, they were usually held on the rock of the Pnyx, where a semicircular space, partially formed by excavation from the native rock, and containing 12,000 square yards, could accommodate all the Athenian citizens. There were neither seats nor awning, and the assembly met at daybreak. The *bema* on which the orators stood to address the people was carved from the rock, and yet remains. It was often called "the stone;" and as the destinies of Athens were swayed by the orators who stood upon it, it became a figure of speech for the existing government, and the phrase "master of the stone" indicated the ruling statesman of the day. At a later period the assemblies were often held in the great theatre of Dionysus, and also in the Piræus, and in the theatre at Munychia. The right of convening the citizens was vested in the *prytanes*, or presidents of the council of 500, but in times of war or sudden emergency the generals also had the power to call extraordinary assemblies. Any citizen refusing to obey the call was fined. The poorer classes received a small fee for their attendance as a recompense for their time. Before the assembly entered upon any business, a sacrifice, usually of a suckling pig, was offered, and incense was burned. Then the herald proclaimed silence and offered a prayer to the gods; after which, under the direction of the prytanes and the *proëdri*, or heads of tribes, the subjects to be discussed were stated, and permission was given to the speakers to address the people. No measure could be acted upon in the assembly which had not been passed

upon by the senate, but the decrees of the senate might here be approved, altered, or rejected; and a new proposition might be introduced on any subject which had already been discussed in the senate. According to the older regulations, persons above 50 years of age had the privilege of speaking first; but this distinction was obsolete in the days of Aristophanes. No new decree could be publicly proposed till it had been shown to the proëdri, that they might see whether it contained anything injurious to the state or contrary to existing laws. The people voted either by show of hands or occasionally by ballot. The assembly could make inquisition into the conduct of magistrates, and in turbulent times exercised a power resembling that of impeachment, as in the cases of Demosthenes and Phocion. It was sometimes suddenly broken up at the occurrence of an unfavorable omen, as thunder and lightning, sudden rain, or any unusual natural phenomenon.—In later Greek and Latin the name signified the church.

ECCLESIASTES, or *The Preacher* (Heb. *Koheleth*, assembler), one of the didactic books of the Old Testament canon, professing to be the words of the preacher, the son of David, king in Jerusalem. It contains allusions to the writer's riches, palaces, and parables, and its sententious style reminds one of the author of the Proverbs. Yet its diction is marked by Chaldaisms and linguistic usages which are thought not to have been introduced into the Hebrew language till about the period of the Babylonish captivity. The authorship of Ecclesiastes was attributed to Solomon by nearly all the rabbinic commentators and patristic writers; but in modern times this view has been relinquished by all the writers of the various liberal schools without exception, and even by theologians like Hengstenberg, Stuart, and Keil; in fact, no prominent theologian of the 19th century has defended it. According to Hengstenberg and Keil, the book was compiled in the time of Nehemiah; according to Hitzig, about 200 B. C.; and according to Grätz, not until the Herodian time. Some entertain the opinion that its original form must have been a dialogue in which the sage carries on a discussion with a skeptic and a libertine. Yet it is more commonly regarded as the monologue of a Hebrew moralizing on life and searching for the highest good, scanning the perversities and follies of man, and at length, after a review of the evidence, declaring the verdict that obedience to God is the only real and substantial good.—Among the best commentaries on this book are those of Knobel (1836), Hitzig (1847), Stuart (New York, 1851), Elster (1855), Vaihinger (1858), Hengstenberg (1859; English translation, 1860), Ginsburg (London, 1861), Ewald (2d ed., 1867), and Grätz (1871).

ECCLESIASTICUS, one of the apocryphal books of the Old Testament, called also "The Wisdom of Jesus, the Son of Sirach." The author

appears to have lived in the 3d and 2d centuries B. C., and wrote in Hebrew, though no copy of the Hebrew original has been preserved; and his work was subsequently (probably about 130 B. C.) translated into Greek by his grandson. The book contains—1, an anthology of moral and prudential precepts for the various circumstances of life; 2, a discourse which the author puts into the mouth of wisdom herself, inviting men to virtue; and 3, a panegyric in which the author celebrates the praises of God and eulogizes the great men of his nation. In the Roman Catholic church it has been held as canonical since the council of Carthage, whose decision was confirmed by the council of Trent. The best commentary on the book is by Fritzsche (1859).

ECHEVEIS. See SUCKING FISH.

ECHEVERRIA, Estéban, a South American poet, born in Buenos Ayres in 1809, died in Montevideo in 1851. He published his first poems in 1829, subsequently went to France, and on his return prepared several other volumes, after the style of Byron and Lamartine. *La cautiva* (1837), his best poem, contains exquisite descriptions of the pampas and the Argentine people. Rosas expelled him from Buenos Ayres, and he spent the latter part of his life in Montevideo, where in 1849 he published *La insurreccion del Sud*.

ECHIDNA. See PORCUPINE ANT-EATER.

ECHENADES, in ancient geography, a group of islands in the Ionian sea, off the coast of Acarnania, near the entrance of the gulf of Corinth. They were said to have been formed by the alluvial deposits of the river Achelous; and Herodotus says that many of them in his time had become reunited to the mainland. They took their name from the *echinus*, or sea urchin, in consequence of their sharp and prickly outlines. The largest of them was Dulichium, now a part of the mainland. Homer describes them as inhabited, but later writers speak of them as barren and deserted.—They are now called the Curzolari islands, and have five small villages, but their size is so small, and their productions so few, that they are of little importance. Lord Byron during his voyage from Cephalonia to Missolonghi, in January, 1824, took refuge among them, twice from storms and once from a Turkish cruiser. The great battle of Oct. 7, 1571, commonly called the battle of Lepanto, was fought off these islands instead of off the city of Naupactus, or Lepanto, and within the gulf, as the name implies.

ECHINODERMS, or *Echinodermata* (Gr. *ἐχίνορ*, a hedgehog, and *δέρμα*, skin), the highest class of radiated animals, so named from the spines with which many of the genera are covered. They all have a tough envelope, containing calcareous particles, or a kind of shell of movable pieces, provided with tubercles or spines; the oral or actinal region is beneath, the aboral or abactinal above, the parts radiating from the former and meeting above; along

certain of the rows of plates are perforations for the ambulacra or suckers used in locomotion, and between them the spine-bearing plates, when these exist. They have well developed muscles, and a nervous ring around the oesophagus, which sends off branches to the rays, which are generally five or a multiple of five. Respiration is by means of branchiæ, by organs performing other functions, and by water passing into the general cavity of the body. They reproduce by means of eggs, and abound in almost all seas; some of the lower orders were among the earliest created animals, and the class ranges from the Silurian to the present epoch. They embrace the five orders of crinoids or stone lilies, ophiurans or brittle stars, asterioids or star fishes, echinoids or sea urchins, and holothurians or sea cucumbers, the last being the highest, and seemingly a connecting link between radiates and articulates. There is a remarkable persistency of form in the class from the earliest to the present time, some of the oldest being referred by Goldfuss to existing genera. They are essentially carnivorous.

ECHINUS, a genus of echinoderms, the type of the order echinoids, represented by the sea urchins or sea eggs common on our coast.

Sea Urchin, top view.

They have globular cases with flat bases, formed of calcareous plates accurately fitted together in rows of larger alternating with smaller plates, the former covered on the outside with movable spines; in some species they are 5 or 6 in. long, exceeding the diameter of the body. These spines fit by a ball-and-socket joint into little depressions, which occupy the centre of tubercles that cover the larger or ambulacral plates, and by the movement of the muscles which are attached to them they admit of considerable motion. Besides these organs of motion, upon which the weight of the animal not buoyed up by the water is sustained, hundreds of tubular feet, or ambulacra, project through openings in the smaller interambulacral plates. These may be thrust out beyond the spines, and, having a little sucker at their ends, they serve to take hold of any object that comes in contact with them; and

thus the animal may cause the shell to roll slowly, the spines aiding the motion. The tubular feet also serve to seize their prey, one foot after another fastening to it and passing it around to the mouth, which is in the centre of the under portion of the shell. This being furnished with a powerful arrangement of teeth, small shellfish and crabs are easily masticated. —The echinoids are divided into regular and irregular. The former, containing the globular

Sea Urchin (*Toxopneustes drobachiensis*).

genera, have the mouth below and the vent above, both central, and the ambulacra in five pairs continuous from vent to mouth; the dental apparatus is complicated. They vary from 1 to 4 in. in diameter, with spines of equal length. The common sea urchin of the American coast (*toxopneustes drobachiensis*, Ag.) is generally about an inch in diameter, and will be easily recognized by the above general description and by the figures. Some of the

Rotula.

large species of tropical climates are used as food. In the *cidaris* family, which includes those best known, are more than 20 genera. The irregular echinoids have the mouth below, the vent sometimes below, sometimes at one side, and the ambulacra not continuous. In the family *clypeastridae*, in which the ambulacra resemble the petals of a flower, are the flat sea urchins, *echinarachnius parma* (Gray) and *mellita quinquefora* (Ag.), which are cov-

ered with soft velvety spines, living on sandy shores, where they lightly bury themselves, only discoverable after storms or in still days when they slowly change their places. In the globular forms the eye specks, which are at the end of the rays in the star fish, are drawn close together at the summit; at the same place is a curious little sieve or madreporic body, through which water is admitted to the five principal tubes of the interior. Sea urchins are able to bore holes in the hardest rocks, in which they lodge, enlarging the cavity as they increase in size, the opening remaining the same, so that they are prisoners for life. It is generally believed that they thus penetrate and excavate rocks by the constant motion of the microscopic vibratile cilia which cover their spines. The heart-shaped sea urchins, the spatangoids, bury themselves in mud

Mellita quinquefora.

and sand. Sea urchins are found from the upper Silurian to the present time; they were very abundant in the mesozoic age, especially in the chalk epoch.

ECHO (Gr. *ἠχώ*, from *ἠχέ*, a noise), a sound reflected by an opposing surface and repeated to the ear of a listener. The nature of those pulses that are propagated through the air to the ear and produce the sensation of sound is fully explained under the latter title, where also it is shown that the sound pulse is partly reflected when it encounters in its path a medium of different elasticity or density; if the reflected sound reach the observer so long after the original sound as to constitute a distinct noise, it is called an echo. Simple echoes, and even those that repeat several times in succession the words of the human voice or other sounds, are familiar to all. Of more remarkable cases we may instance the following. A writer in 1766 states that at the Simonetta palace near Milan there was an echo that repeated 60 times the sound of a pistol; this echo does not now exist. Sir John Herschel quotes the case of an echo at Woodstock park that repeats 17 syllables in the daytime and 20 at

night. Dr. Page (1839) notices one at Belvidere, Allegany co., N. Y., that repeats three syllables distinctly 11 times, the observer standing between two barns. Most remarkable, however, are the phenomena of harmonic echoes, or those that repeat in a different key the direct sound. Dr. Page observed such an echo in Fairfax co., Va., which repeats 13 syllables three times; and if 20 notes be played on a flute, they are returned with perfect distinctness, but some of them are raised in pitch by a third, a fifth, or an octave, the effects varying with the state of the atmosphere. Tyndall describes the echoes of the Alpine horn rebounding from the rocks of the Wetterhorn or Jungfrau as dying away in successive reflections, gradually becoming more soft and flute-like. Dr. Brewer in his work on "Sound and its Phenomena" (1864) instances the following cases: Not far from Coblenz an echo is found that makes 17 repetitions at unequal intervals, some loud, some soft; some to the right, others to the left of the observer; some in unison with the direct sound, others a third, fifth, or tenth of the fundamental. At the lake of Killarney is an echo that renders an excellent second to any simple air played on the bugle. Some distance from Glasgow there was formerly a remarkable case in which eight or ten notes of a trumpet were repeated a third lower, and again a second and third time, each time lower still. The Hon. J. W. Strutt, now Lord Rayleigh, observed ("Nature," 1873) the sound of a woman's voice echoed from a plantation of firs, but its pitch raised an octave; with a man's voice the phenomenon could not be produced.—The various interesting peculiarities of echoes depend upon the conditions under which the reflection takes place, and the position of the observer with respect to the reflecting surfaces; these conditions may be so varied as to more or less affect the intensity and the quality of the original sound, and we will separately consider these two peculiarities. The intensity of a sound varies, other things being equal, directly as the solid angle included at the origin of the sound between the extreme limits of the wave that enters the observer's ear. If the reflecting surface be plane and so small that it subtends a smaller angle than the tympanum of the ear, the intensity of the observed echo will be diminished in proportion to the size of the reflector. If the effective surface be larger than this limit, and nothing of intensity be lost in the act of reflection, the echoes will be as loud as the direct sounds that have passed over the same length of path. There is however always in the act of reflection an actual loss, depending on the relative density and elasticity of the air and the reflecting body; this principle is applied to deaden the echoes within a poorly contrived auditorium, by encasing the bare walls in wooden panels or draping them with any light material. Two planes may be so placed that the reflected sounds proceeding from each reach the ob-

server at the same instant; he will then perceive an echo of twice the intensity of that produced by either reflector separately. The curvature of an elliptical mirror is such that all the rays of sound, or to speak more properly the whole wave of sound, that starts from one focus will be reflected precisely to the other focus, so that the ear placed at this point perceives a sound as intense as that at the origin; this principle is applied in the construction of whispering galleries, where, however, circular or other curved surfaces frequently replace the ellipse. If a sound originate near the focus of a parabolic mirror, the reflected portion of the wave will be confined to a cylindrical or conical space in front of the mirror; a principle that finds application in the construction of speaking trumpets and tubes, ear trumpets, sounding boards for pulpits, &c. The louder portions of the rolling of artillery or of a clap of thunder are doubtless sometimes the effect of a concentration of several echoes reflected from objects properly placed with respect to the observer. On the other hand, a convex surface scatters the waves of sound and diminishes the intensity of the echo; a principle that finds frequent application in the construction of large halls, whose walls, ceilings, pillars, &c., are covered with protuberant convex ornaments. If the reflecting surfaces are arranged in a promiscuous manner, there will be heard a confused mixture of echoes, each perhaps so faint that the direct sound greatly preponderates; and in the case of many public halls it will be noticed that if empty the speaker's voice is unpleasantly reëchoed, while if filled by an audience the echoes become much subdued and often inappreciable. So also a wave of sound passing through a mixture of heterogeneous bodies (such as a forest, currents of hot and cold air, a glass full of champagne, a stratum of rock full of faults and fissures, &c.) is quite completely broken up into smaller pulses moving in every possible direction. Thus fog bells and whistles, and indeed all other sounds, are heard further during cloudy and foggy weather, and during the night, when the earth is shaded from the sun's heat; and balloonists testify that during the night they hear terrestrial sounds more distinctly. A mixture of rapid currents, even if the liquid be homogeneous, has the same effect; so that the attempts made in 1870 during the siege of Paris to send sound signals through the waters of the Seine were quite unsuccessful, the range of distinct hearing being far less than in the quiet waters of a lake.—The nature of a pulse of sound is such that if two or more pulses meet under certain conditions they will interfere with each other so as to produce silence instead of sound at the point of their intersection. The echoes within rooms of regular symmetrical proportions do thus interfere with each other, and to a slight extent with the direct waves of sound, so that the loudness of the sounds perceived by the ear varies greatly

with a change of position of a few feet. In order that reflected waves should thus produce silence, they must have travelled over paths differing in length by some odd multiple (3, 5, 101, &c.) of a half of the wave length peculiar to the pitch of the sound in question. Because of the variety in the length of the waves that issue from the vocal organs, it follows that a point in an auditorium may be unfavorable to the perception of certain notes in the speaker's voice or in the music of an orchestra, yet favorable to the perception of all others. In the study of the acoustic properties of public halls, Langhans (1810) and Orth (1871) have made valuable investigations. Some of their results are as follows: 1. The phenomena of interference are of minor importance as disturbing elements, while the principal evil to be avoided is the confusion and repetition of echoes. 2. It is less important to provide for the concentration of the sounds of the speaker's voice than for the suppression of all echoes. 3. A difference of path between the direct and the reflected sounds of from 15 to 22 ft. does not disturb and may even assist the hearing; a difference of from 185 to 215 ft. may be disregarded because of the comparative feebleness of the echo; a difference of 30 ft. is to be avoided, as being the most annoying. 4. Low roofs, as in theatres, are advantageous; high ceilings, as in Gothic churches, are of no decided advantage, and may help to produce undesirable echoes. 5. If wood panelling or plaster is introduced to deaden the echo, it is most important to attend to the backing by which the panels are fastened to the walls.—The pitch of an echo, like that of any sound, depends on the rapidity with which the individual pulses encounter the tympanum. When these pulses follow each other at the rate of from 10 to 16 per second, the ear ceases to be able to separate one from another, and the whole are merged in an apparently continuous humming noise or a musical note of low pitch; the pitch increases directly as the rapidity of the pulsation. If the pulses occur at irregular intervals, and with unequal intensities, a noise or a sense of confusion is produced. These principles find an application in the case of sound reflected from a series of plane reflecting surfaces, such as the palings of a fence, a row of square pillars, &c.; in these cases the original sound does not appear to be echoed, but instead thereof we hear a musical note, generally of high pitch, lasting for a second or two only, and rapidly diminishing in intensity; if the observer be in motion, the individual echoes reach his ear more or less rapidly than if he be stationary, thus producing a corresponding change in the pitch. Lord Rayleigh has shown that a group of bodies whose dimensions are quite small in comparison with the wave lengths of sound reflect the first harmonic or octave 16 times more powerfully than the fundamental tone; and in general the reflecting or diverting power of

small obstacles varies inversely as the fourth power of the wave length. When therefore a composite note, such as those of the human voice, is echoed back from such a group of objects, the notes of higher pitch will be returned in far greater proportion, and the general effect will be that the echo appears to be pitched in a higher key than the original. On the other hand, the direct wave, being shorn of its higher elements, will appear to be duller than the original, and may appear to have fallen an octave, since it is well known that pure tones are apt to be estimated too low. It is therefore evident that the sounds from any musical instrument, if echoed from a proper group of surfaces, will be shorn of the lower or fundamental tones and appear pitched a third, a fifth, &c., higher, as in the harmonic echoes above enumerated; while on the other hand, if echoed from a plane surface studded with small obstacles, they may be deprived of those higher rates of vibration that constitute the peculiarities of timbre or quality, and be reduced to their fundamental vibrations, whereby the notes from the various instruments are made to sound more like each other, as in the case quoted above from Tyndall. If, on the other hand, a pure tone be echoed from a sounding board or other elastic surface, there are induced in the latter such subordinate harmonic vibrations as it may be capable of, and these communicated to the air return to the ear along with the fundamental note, thus producing an effect as to quality of tone precisely the reverse of that observed by Tyndall.

ECHO, in Greek mythology, an oread nymph, daughter of the earth and air. While Jupiter waned with the other nymphs, she detained Juno with endless speech. As soon as Juno understood the device, she changed the nymph into an echo. Thus transformed, Echo withdrew to the banks of the Cephissus, not far from Athens, at the foot of Mt. Pentelicus, and became so desperately in love with Narcissus, son of the river god, that she followed him through the forests, in the chase, to the darkness of grottoes, and to the borders of fountains, and ever repeated in solitary places the name of her beloved. Narcissus disdained her passion; and she retreated into the depths of the woods, and pined away in secret. Only her plaintive voice was always heard in the distance, and it was said that her bones were changed into rocks, and her voice alone remained. She was avenged by Nemesis, who inspired Narcissus with a passion for himself.

ECHOLS, a S. county of Georgia, bordering on Florida and intersected by the Allapaha river; area, about 400 sq. m.; pop. in 1870, 1,978, of whom 465 were colored. The surface is level, the soil sandy. The chief productions in 1870 were 41,814 bushels of Indian corn, 7,947 of oats, 10,937 of sweet potatoes, and 457 bales of cotton. Capital, Statesville.

ÉCJA (anc. *Astigi*), a city of Andalusia, Spain, on the Genil, in the province and 47 m.

E. N. E. of the city of Seville; pop. about 30,000. There are several fine residences in the city, a pretty theatre, a handsome square, and a charming promenade outside the town. In the Plaza de Toros some of the best bull fights in Spain take place. From its excessive heat the town is called the *sartenilla* (frying pan) of Andalusia. Its industry consists chiefly in the manufacture of woollens, linen, silk, and oil, and tanning. Écija was for a long time in the middle ages an important border town between the Moors and Christians, and the scene of many romantic adventures. Inscriptions and relics of antiquity still exist here.

ECK, or **Eckins**, **Johann Mayr von**, a German theologian, born in Eck, Swabia, Nov. 13, 1486, died in Ingolstadt in 1543. The son of a peasant, he acquired, by a profound study of the Christian fathers and the scholastic philosophers, an erudition and skill in disputation which Luther and Melancthon much admired. He was doctor of theology, canon of Eichstädt, and vice chancellor of the university of Ingolstadt, when in 1518 he appeared as an adversary of Luther by his notes upon the theses of that reformer. He met Luther and Carlstadt in the conferences at Augsburg and Leipsic, but failing to convince them, he went to Rome to urge severe measures against them. He returned to Germany with a papal bull of condemnation, but at Leipsic the people had so warmly embraced the new doctrines that he saved himself from violence only by retreating to a convent. He subsequently labored fruitlessly to reunite the divided church.

ECKERMANN, **Johann Peter**, a German author, born at Winsen, Hanover, in 1792, died in Weimar, Dec. 3, 1854. He assisted Goethe in his last edition of his complete works, and was named in his will editor of his literary remains, which were published in 1832-'3. In 1839-'40 he edited Goethe's works complete in 40 volumes; but the work which won for him much reputation was his *Gespräche mit Goethe* (3 vols., Magdeburg, 1836-'48). Extracts of this work were translated into many foreign languages, including the Turkish. The first English translation was made by Margaret Fuller, and published at Boston in 1839. Another English translation by John Oxenford appeared in London in 1850.

ECKERSBERG, **Christoph Wilhelm**, a Danish historical, marine, and portrait painter, born near Apenrade, Jan. 2, 1783, died in Copenhagen, July 22, 1853. He studied at the Copenhagen academy, and in Italy and France. Rising rapidly to considerable distinction, he was in 1817 made an academician, and almost immediately a professor at the academy. Among his important works are his picture of Moses commanding the Red sea to close after the passage of the Israelites, "Death of Baldur," a scene from Oehlenschläger's "Axel and Walpurga," and "Roadstead of Helsingfors."

ECKFORD, **Henry**, an American ship builder, born in Irvine, Scotland, March 12, 1775, died

in Constantinople, Nov. 12, 1832. He served his apprenticeship in Quebec, and in 1796 removed to New York, where he introduced many important changes in the art of ship building. During the war of 1812 he built a fleet of vessels of war for the United States on the lakes with great rapidity, cutting the timber from the forests and transporting the equipments from the seaboard. After the war he constructed the Robert Fulton, which made in 1822 the first successful voyage by steam to New Orleans and Havana. He was for a time naval constructor at the navy yard in Brooklyn, and he also built war vessels for various European and South American powers. In 1831 he built a sloop of war for Sultan Mahmoud, and was invited to enter his services as naval constructor. He took up his residence in Constantinople, organized a navy yard there, and laid the keel of a ship of the line, but did not live to see it completed.

ECKHART, Meister (master), the father of German mysticism, born probably in Strasburg in the middle of the 13th century, died probably in Cologne about 1328. He studied theology and philosophy in Paris, became a Dominican friar in Rome, and afterward provincial of the order in Germany, vicar general for Bohemia, and prior in Frankfort-on-the-Main. His attempts to reform the Dominican convents and his exalted mysticism caused him to be suspected of heresy, and in 1327, while he was in Cologne, Archbishop Henry substantiated the charge before a tribunal of the inquisition. A papal bull was issued against his writings, March 27, 1329, which declared that he had recanted before his death. This alleged recantation merely consisted, according to a document of Feb. 13, 1327, still extant, in his protest against the malicious interpretation of garbled passages from his doctrines, which in his opinion had never transcended the bounds of orthodoxy. Tauler, Suso, and other eminent men were among his disciples, who cherished his memory as a profound thinker, a lucid expounder of the most abstruse speculation, and one of the best German prose writers. The second volume of Pfeiffer's *Die Deutschen Mystiker des 14. Jahrhunderts* (Leipsic, 1857) contains his preserved sermons and treatises. See also Bach's *Meister Eckhart, der Vater der deutschen Speculation* (Vienna, 1864).

ECKMÜHL, or **Eggmühl**, a village of Bavaria, on the river Grosse Laber, 13 m. S. S. E. of Ratisbon, memorable for the great victory gained there by Napoleon over the Austrians under the archduke Charles, April 22, 1809. Marshal Davoust, having especially signalized his valor during the engagement, was created prince of Eckmühl. This battle, and the minor actions of Abensberg (April 20), Landshut (21), and Ratisbon (23), which closely preceded or followed it, cost Austria 25,000 men, and obliged the archduke Charles to retire into Bohemia, and to leave open to Napoleon the highway to Vienna.

ECKSTEIN, Ferdinand, baron d', a French publicist, born of Jewish parents in Denmark in 1790, died in November, 1861. He became a convert to Catholicism, took part in the campaigns of 1812-'14, held various offices under the Bourbons in France, who conferred on him the title of baron, and retired from public life in 1830. From 1826 to 1829 he conducted a periodical, *Le Catholique*, in which he advocated the religious views of De Maistre and De Bonald. Among other works he published *De l'Espagne, Des Jésuites, De l'Europe, and Des sources de l'opinion publique en Europe*. He was an orientalist, and at his death was engaged on a *Histoire des origines de l'humanité*.

ECCLECTICS (Gr. ἐκλέγειν, to select), a class of ancient philosophers who professed to select whatever was good and true from all the other philosophical sects, that they might combine it in a new system. They held Plato in the highest esteem, but did not hesitate to add to his doctrines whatever they thought conformable to reason in the tenets of the other schools, or to reject whatever they disapproved. The eclectic system is supposed to have originated with Potamon of Alexandria, a Platonist; it flourished at Alexandria about the beginning of our era; and it reached its perfection under Ammonius Saccas, who blended Christianity with his views, and founded the Neo-Platonic sect of the Ammonians toward the end of the 2d century. The moral doctrine of the Eclectics was, that the mind of man, originally part of the Divine Being, having fallen into darkness and defilement through its connection with the body, is to be gradually emancipated from the influence of matter, and rise by contemplation to the knowledge and likeness of God; and that this result, which is the great end of philosophy, is to be attained through abstinence, voluntary mortification, and religious exercises. In the infancy of this school, not a few professors of Christianity were led to think that a coalition might advantageously be formed between its system and that of the gospel. The only consequence was the corruption of the doctrines of the New Testament, by their mixture with pagan ideas and opinions. One of the most eminent Eclectics was Proclus, an edition of whose works was prepared by Victor Cousin (6 vols., Paris, 1820-'27), who used the term Eclecticism in a different sense to represent his own philosophical system.

ECLIPSE (Gr. ἐκλείπειν, to fade away, vanish), the obscuration of one celestial body by another, whether by intercepting the light coming from it or the light illuminating it. Eclipses of the former kind are sometimes called eclipses, sometimes occultations, and sometimes transits. Thus when the moon hides the sun's face wholly or in part, the phenomenon is called an eclipse of the sun or a solar eclipse; but when the moon conceals a star, the phenomenon is called an occultation of the star. Again, when Jupiter or Saturn hides one of his satellites by intervening between the earth and that

satellite, the event is called an occultation of the satellite; but when a satellite of Jupiter hides a portion of the planet, a transit of the satellite is said to be in progress; and when Venus or Mercury hides a portion of the sun's face, a transit of Venus or Mercury is said to be in progress. Events of the second kind are called eclipses in nearly all cases, but occasionally the transit of a shadow. Thus if the earth's shadow falls upon the moon, so as to obscure her face either wholly or partially, the phenomenon is called an eclipse of the moon; so also if the shadow of Jupiter or Saturn obscures a satellite of either planet, the phenomenon is called an eclipse of the satellite; but when the shadow of a satellite of either planet falls upon the planet, a transit of the shadow is said to be in progress.—For the principal phenomena presented during a solar eclipse, see SUN. It is only necessary to mention here that, owing to the various distances of the sun and moon, a solar eclipse may be total or annular when central; that is, either the whole face of the sun may be concealed, or a ring of the sun's light may remain visible all round the disk of the moon. When the eclipse is not central, so that at the moment of greatest obscuration a crescent-shaped portion of the sun remains visible, the eclipse is said to be partial.—In lunar eclipses the shadow of the earth seldom falls very nearly centrally upon the moon; yet owing to its great breadth at the moon's distance, the moon is often totally immersed in the shadow. When this happens the phenomenon is called a total lunar eclipse. When the moon passes only in part into the earth's true shadow the phenomenon is called a partial lunar eclipse. As the earth's shadow is surrounded by a penumbra, it occasionally happens that the moon passes partly within the penumbra without reaching the true shadow. Such phenomena have been called penumbral lunar eclipses. It might be supposed that when the moon is totally immersed in the true shadow of the earth she is totally obliterated from view; but this seldom happens. Usually the moon in the heart of the earth's shadow presents a dark red or copper-colored disk. It is believed that the light which thus illuminates her is sunlight which has undergone refraction by the earth's atmosphere. Indeed, it is demonstrable that if the moon is centrally eclipsed, even when she is nearest to the earth, a visual line from any point of the moon tangential to the earth's globe would be so bent by refraction in its passage through the earth's atmosphere as to reach the sun's disk; so that an inhabitant of the moon would see a ring of reflected sunlight all round the earth's disk during one of these total eclipses. But this would not happen if all those parts of the terrestrial atmosphere which bordered on the earth's visible half were cloud-laden; and this is believed to be the reason why occasionally the moon disappears wholly from view when totally eclipsed.

ECLIPTIC, the great circle of the heavens along which the sun appears to travel in the course of a year. It is inclined at an angle of about $23^{\circ}28'$ to the celestial equator. The name is derived from the fact that the light of the sun or moon can only "pass away" when the moon is on or near the ecliptic. The ecliptic is divided by astronomers into 12 equal portions, each of 30° . These are called signs, and supply the means of indicating the annual progression of the sun. They commence with the point where the ecliptic crosses the equator passing from south to north. This point is called the first point of Aries, and is indicated by the sign φ ; and Aries extends 30° along the ecliptic eastwardly, that is, in the direction of the sun's motion, from this point. Then follow successively the signs Taurus τ , Gemini Π , Cancer \mathcal{C} , Leo Ω , Virgo mg , Libra \mathfrak{L} , Scorpio M , Sagittarius \downarrow , Capricornus V , Aquarius A , and Pisces X . These signs, whether regarded as ecliptical or zodiacal, are not identical with the corresponding zodiacal constellations, each of which, owing to precession, has been carried so far forward as to agree very nearly with the next sign. Thus the constellation Pisces corresponds very nearly with the sign Aries, the constellation Aries with the sign Taurus, and so on. The sun enters Aries at the vernal equinox, on or about March 21, Taurus on or about April 20, Gemini on or about May 21, Cancer on or about June 21 (the summer solstice), Leo on or about July 22, Virgo on or about Aug. 23, Libra on or about Sept. 23 (the autumnal equinox), Scorpio on or about Oct. 23, Sagittarius on or about Nov. 22, Capricornus on or about Dec. 21 (the winter solstice), Aquarius on or about Jan. 20, and Pisces on or about Feb. 19.

ECUADOR, a republic of South America, named from its situation under the equator. It lies between lat. $1^{\circ}50'$ N. and $5^{\circ}30'$ S., and lon. $69^{\circ}52'$ and $80^{\circ}35'$ W., and is bounded N. by the United States of Colombia and Brazil, E. by Brazil, S. by Peru, and W. by the Pacific. The Ecuadorians assert their right to the province of Mainas, S. of the Marañon; but most geographers assign that river as the greater portion of the southern boundary, adopting for the northern a right line drawn from the northernmost mouth of the river Mira E. by S. to the Caqueta or Japurá, some 30 m. below the confluence of the Mesai, the Caqueta itself forming the remainder of the boundary to lon. $69^{\circ}52'$ W. The extreme length of the republic would thus be about 740 m. from E. to W., and the greatest breadth 520 m. from N. to S. The area, according to the best estimates, is about 252,000 sq. m., and that of the Galápagos islands 2,951, making a total area of 254,951 sq. m.—The coast presents a sinuous convex line, about 700 m. long, with a general bearing from S. W. to N. E. Principal among the numerous indentations is that formed by the gulf of Guayaquil, 80 m. wide, at the mouth of the river of the same name. Further northward

are the bays of Santa Helena, Callo, Carácas, Mompiche, and Pailon. Mompiche bay is S. of Cape San Francisco, and Carácas S. of Cape Pasado. Point Santa Helena, a rocky promontory, is the most westerly land in the republic; and the whole coast from that point to Punta Galera, 350 m. northward, including the sinuosities, is of the same character as the promontory. Besides the Galápagos, which will be treated under that title, Ecuador possesses numerous islands, most of which are in the immediate vicinity of the coast. The principal of these are Puná, at the mouth of the Ría de Guayaquil (the landing place of Pizarro in 1531 when on his way to conquer Peru), Santa Clara, La Plata, and Tumaco. Of the three ports, that of Guayaquil, sheltered by the island of Puná, is the most important; it is one of the best on the Pacific, and monopolizes the maritime commerce of the republic. Esmeraldas, on the Río Esmeraldas, has anchorage for ships of small draft. Manta is now abandoned to coasters.—No country in the world presents a more varied surface than that of Ecuador; about nine tenths of it is composed of snow-clad mountains, dense forests, and vast *llanos* or savannas. To the east extend interminable forests and immense plains, intersected by rivers, lagoons, and marshes, and interrupted by mountain ranges stretching from the Andes obliquely to the banks of the Amazon. To the west the country is covered with extensive forests, with less lofty mountains, and cut by rivers of lesser magnitude. The centre swells into two Cordilleras separated by a valley 300 m. long, with snow-covered peaks, ranking among the loftiest of the earth. The valley is remarkable as being, next to the basin of Titicaca, the centre of the most ancient native civilization of America. The Andes enter the republic by the mountain knot of Loja, where they separate into two chains parallel to each other and to the coast, traversing the state in a N. N. E. direction, until the chains again unite in the mountain knot of Pasto, near the northern limit. At two points transverse ridges link the two parallel chains together, dividing the large valley into three smaller ones, named severally, commencing at the south, Cuenca, Alausí and Ambato, and Quito. The first of these cross ridges occurs about lat. $2^{\circ} 27' S.$, and takes its name from the trachytic range of Asuay, which attains an elevation of 15,440 ft.; and the second, the Alto de Chisinche, only 500 ft. above the surrounding plain, about lat. $0^{\circ} 40' S.$ This latter ridge forms the Ecuadorian watershed between the Atlantic and Pacific. The elevation of the valleys varies from 8,500 to 14,500 ft., that of Quito having a mean elevation of 9,540 ft. None of the mountains bordering the southern valley, Cuenca, reach the line of perpetual snow. The principal summits are comprised between lat. $2^{\circ} 27' S.$ and $1^{\circ} N.$, the eastern range, or Cordillera Oriental, maintaining the greatest general elevation, although

Chimborazo, the culminating point of the system, 21,422 ft. above the sea, is in the Cordillera Occidental or western range. The other noteworthy peaks in the Cordillera Occidental are: Iliniza (17,380 ft.), Pichincha (15,924), Carihuairazo (15,920), Chiles (15,960), and Cumbal, about 1,500 ft. above the snow line, which in Ecuador is a little above 14,000 ft. The principal summits of the Cordillera Oriental are Cayambi (19,813 ft.), the only volcano on the globe immediately under the equator; Sara Ureú or Supai Ureú (17,276 ft.), 35 m. E. of Quito, forming part of a ridge known by the name of Guamaní; Antisana, 35 m. S. E. of Quito (about 19,200 ft.), Cotopaxi (about 19,500), Llanganate (18,639), Tunguaragua (16,424), Altar (17,126), and Sangay (16,138). Nowhere in the whole system of the Andes are more colossal mountains than those on either side of the valleys of Quito and Ambato, $2^{\circ} S.$ and $0^{\circ} 15' N.$ of the equator. Many of these are volcanoes, a few being extinct, and the others in activity. The whole table land of Quito constitutes one vast volcanic hearth, the subterranean fire bursting sometimes from one and sometimes from another of the openings, which have generally been regarded as independent volcanoes. The country between the Andes and the Pacific is intersected by spurs detached from the western chain, and gradually sinking into low hills as they approach the coast, except the portion adjacent to the Ría de Guayaquil, which is a plain several miles in extent, and so low as to be inundated during the flood. Swamps prevail also in this region.—The Amazon, here called the Marañón, on the southern boundary, receives the waters of several tributaries taking their rise within the territory of Ecuador. The most important of these is the Napo, which, rising in the eastern declivities of Cotopaxi and Sincholagoa, holds a generally S. E. course through the plains of Oriente to its junction with the Amazon, a distance of about 600 m., receiving the Arajuno, Yasuní, Coca, Agnáríco, Curaray, and other tributaries. It is navigable by steamers from its mouth to the confluence of the Coca, about 400 m.; above that point the natives navigate it in canoes. Orellana, the first European who navigated the Amazon, embarked on the Coca, a few miles above its junction with the Napo. The Pastaza has a course of 540 m., about 270 of which are navigable by steamers, and 60 more by small craft; it takes its rise in the same region as the Napo, and joins the Amazon in lat. $4^{\circ} 35' S.$, lon. $76^{\circ} 35' W.$ The upper part of this river is called Patate. The Santiago, flowing from the lakes Quinuas, Cajas, and Culebrillas, in the valley of Cuenca, maintains first an easterly and afterward a southeasterly course, and falls into the Marañón near the town of its own name, and in the vicinity of the falls of Mauseriche; its length is 500 m., and it may be navigated by steam for 300 m.; it receives the waters of the Zamora and other important streams. Besides the foregoing,

there are the smaller rivers Chinchipe, Morona, Tigre, and a few others, navigable for greater or lesser distances. N. of the Napo are the Putumayo and the Caqueta or Japurá, both of considerable magnitude, but neither wholly within the territory of Ecuador. The first enters it near San Miguel, and after traversing the northern portion of Oriente in a generally S. E. direction, flows through the Brazilian forests to the Amazon. The second constitutes part of the N. boundary line of the state. All the rivers on the W. side of the Cordillera Occidental hurry by briefer courses to the Pacific. The Guayaquil is formed by the union of numerous streams issuing from the mountains adjacent to Chimborazo, and falls into the gulf of Guayaquil; it is navigable as far as Babahoyo, 75 m., and receives the waters of the Baba and the Daule. The Mira falls into the sea by several mouths at the northern extremity of the coast; the Esmeraldas into the Ancon de Sardineas; the Chones and the Charapotó into Carácas bay; and the Jubones and the Tumbez into the bay of Tumbez. All these, except the Guayaquil, are only navigable by boats, rafts, and small craft. Ecuador has no lakes properly so called; but there are many lagoons, some in connection with the various tributary streams of the Marañon, others in the elevated table land formed by the eastern and western Cordilleras, and a few in the high plains of the Cordilleras. The Yaguarcocha, in the plains of Imbabura, is one of the largest. In the province of Guayas numerous lagoons are formed in the rainy season, which dwindle into stagnant pools in the dry months.—Little has been done toward the examination of the special structure of the equatorial Andes. The characteristic syenitic rocks and porphyries occur here in as great abundance as elsewhere in the Andine system; yet several important ridges and peaks are observed to be of trachytic formation. Chimborazo, Asuay, and many other mountains of either Cordillera, present the last named character; and extensive tracts in the vicinity of Sangay and Cotopaxi are covered with lava, pumice stone, and cinders; while ruined temples and causeways, the work of the incas, constructed almost wholly of freestone, attest the existence of this last in considerable quantities. Gold, silver, copper, iron, lead, zinc, and sulphuret of mercury occur in various parts. Gold is said to be washed down by most of the rivers descending from the eastern declivities of the Andes; but the gold mines of the elevated mesas of the Cordilleras were, in common with those of silver and mercury, long ago abandoned. At present there are few gold mines, and these only in the mountains near the coast. Antimony, manganese, sulphur, salt, coal, and petroleum are found. But the only productive mining operations are those of iron and copper.—The climate of Ecuador is as varied as the face of the country. In the wooded and marshy regions E. of the Cordilleras and in the

lowlands on the west it is hot and moist; while in the great valley between the eastern and western chains, the climate and temperature vary with the elevation of the plains, or their proximity to the mountains. There are but two seasons, summer and winter. The former, commencing in June and lasting till November, is the season of winds; and the latter, beginning in December and ending in May, is the rainy season. This regular succession of the seasons, however, is known only in the table land between the mountains, and on the plateaus along the declivities of the western Cordillera. Hail and snow storms are common in the elevated plains of the Cordilleras, and frosts destroy the unripe cereals. The direction of the wind changes with the localities. In the great inter-alpine valley, the prevailing wind is from the south, with an occasional norther; but in the more elevated regions the wind currents are almost constantly from the east, sometimes increasing to terrible tempests. In the coast region the south wind prevails in summer and the north wind in winter. In the latter season the copious rains at the head waters of the rivers cause them to inundate the surrounding districts. After the floods subside, the region is for some time covered with a pestilential marsh, which sends forth myriads of noxious insects. Fevers are prevalent during the wet season in the low country, which consequently has few inhabitants of European descent. The climate on the whole is salubrious, particularly that of the valley between the Cordilleras. Intermittent and other fevers are frequent in the coast region; but they are unknown in the highlands, and pulmonary consumption is rarely heard of. Elephantiasis is common at Quito.—In consequence of the equatorial position of Ecuador and its varying elevation, it has in close proximity all the productions of the tropical and temperate zones. In the plains of Quito are produced sugar cane, cotton, and maize, and higher up European cereals and fruits. The low lands produce cacao, coffee, sugar cane, rice, cotton, pepper, tobacco, India rubber, copal gum, vanilla, sarsaparilla, and the tropical fruits, among which are chirimoyas, granadillas, aguacates, plantains, mameys, guavas, and a variety of melons. Besides cinchona (the original home of which is the southern frontier of Ecuador, and especially the region around Loja), there is an immense variety of medicinal roots and plants. The pita or American aloe, and the species of grass called *pajon*, from which are made the so-called Panama hats, are among the most useful productions of the country. The great forests present inexhaustible quantities of timber suitable for every purpose in ship building, house carpentry, and cabinet work. Among the woods are the guachapeli, which hardens in water or in contact with the humidity of the atmosphere, and the sindicampi, which burns freely when fresh cut. Agriculture is in a low condition; the imple-

ments of the husbandman of to-day differ little from those used by his forefathers at the time of the conquest.—Three species of *felida* infest the great forests at the east, the jaguar, puma, and a kind of wild cat. There are also bears, tapirs, several varieties of wild hogs, deer, hares, rabbits, squirrels, armadillos, and monkeys. Among the reptiles are caymans, lizards, adders, and vipers; the great boa, the rattlesnake, coral, equis, tayas, and tigre. Mosquitoes and other noxious insects infest the marshes and coast region. The shores abound in turtles. There are two or three species of condor. Of fishing birds, the principal are the albatross, sea gull, and kingfisher; and there are cranes and ducks of many kinds, pheasants, partridges, pigeons, and a host of others. In the forests are the nightingale, blackbird, thrush, corregidor, and a variety of parrots, parroquets, and other birds of brilliant plumage. The rivers afford an abundant supply of excellent fish. Salt-water fishing is carried on to a considerable extent. Horses, asses, and mules are abundant. The rearing of cattle and sheep forms an extensive industry; and numerous herds of llamas pasture on the páramos. —Manufacturing industry is not extensive in the interior, and still less so on the coast. The natives of the highlands make furniture, saddles, earthenware, and cotton and woollen goods. In Otabalo and elsewhere are factories for linen cloths, damasked quilts, carpets, and drapery for beds, highly esteemed for the delicacy and durability of their colors. About 6,000 ponchos are made monthly at Cotacache, Hatuntaqui, and Guano. There are a few silk-weaving establishments, for which the raw material is mostly imported from France; but some attempts have lately been made to acclimatize the silkworm, which are likely to prove successful. Gold lace is manufactured at Quito, where the women make fine embroidery, needlework, and lace. The manufacture of jipijapa hats constitutes an important industry; some of the hats bring \$40 on the spot where they are made. Large quantities of cheese are made for exportation. Numerous sugar mills are in operation, as also tanneries and iron founderies. Cuenca has many sugar refineries, and is celebrated for its hams and sweetmeats. In Esmeraldas and Guayas immense quantities of cacao are prepared, that of the latter province being among the most esteemed in America. Rum is made from the juice of the sugar cane, and chicha from the yuca and other plants. The production of indigo bids fair to become a source of wealth. Ropes, mats, sackcloth, hammocks, and other articles are made from the fibre of the pita or American aloe. Ship building is carried on to a limited extent at Guayaquil. The implements employed in the foregoing manufactures are for the most part very imperfect; but some of the factories, especially those for cotton, are fitted with American machinery.—The leading articles of export from Ecuador

are cacao, hats, tobacco, cascarilla, leather, India rubber, timber, cundurango, and precious metals and stones. The export trade has been steadily increasing for the last few years; and the value of the exports in 1871 was \$3,045,684, distributed as follows: cacao, \$1,707,400; cascarilla, \$92,102; hats, \$74,256; India rubber, \$693,376; cotton, &c., \$30,816. There were exported in the same year 1,700 quintals of cundurango; and in 1870 precious metals and stones to the value of \$681,280. The imports consist chiefly of manufactured goods, principally from Great Britain, the value of which in 1870 was \$285,040. Cotton fabrics from the same country to the value of \$64,505 were imported in 1871. The total value of the imports is about \$2,500,000 per annum. Some coarse cotton goods are imported from the United States; wines, liquors, cloths, fancy articles, glass, chinaware, hardware, cutlery, &c., from England and France; and, owing to bad mills and worse roads, flour from Chili, and lard from the United States, have to be imported, while wheat and lard are exported from the high lands. The number of vessels which entered the port of Guayaquil in 1870, inclusive of 66 British packets, was 125, with an aggregate of 55,310 tons. There is an important coasting trade between the ports of the republic and those of Chili, Peru, and Colombia.—Hitherto the roads of Ecuador have been among the rudest in South America, and especially those from the coast to the interior; the only one worthy of the name of highway being that from Quito to Bogotá in Colombia. Three roads lead from Quito to the Amazon, and several from the more important cities of the highlands to those on the coast. All are extremely bad, even in the dry season, and become impassable in the wet. The roads to Guayaquil are mule paths; but those to the other seaports have to be traversed on foot. The government has recently decided to build suitable roads, of which some are in process of construction. A cart road, the first in the republic, has been finished as far as Sibambe, where it will unite with the railway of Milagro, soon to be undertaken by the government. Other railways are projected. Steamers already ply between Guayaquil and Babahoyo. There are three joint-stock banks in Guayaquil, and many private banking houses. The national bank was abandoned in 1872 in consequence of an unfavorable banking law passed in 1871.—Ecuador is divided into 13 provinces, which with their respective capitals are as follows:

PROVINCES.	CAPITALS.	PROVINCES.	CAPITALS.
Asuay.....	Cuenca.	Loja.....	Loja.
Chimborazo.....	Riobamba.	Los Rios.....	Babahoyo.
Esmeraldas.....	Esmeraldas.	Manabi.....	Portoviejo.
Galapagos.....	Albemarle.	Oriente.....	Archidona.
Guayas.....	Guayaquil.	Pichincha.....	Quito.
Imbabura.....	Ibarra.	Tunguragua.....	Ambato.
Leon.....	Latacunga.		

The population, according to the census of 1854, was 1,065,500; to which may be added 517,824 for the increase during 18 years, at the

mean annual rate of 2 $\frac{7}{10}$ per cent., as computed by Villavicencio, and 200,000 savages inhabiting the province of Oriente; making a total population of 1,783,324 at the end of 1872. The chief towns are Quito, the capital (pop. about 70,000), Cuenca (32,000), Guayaquil (26,000), and Riobamba (20,000). The population consists of six classes: whites, Indians, cholos or mestizos, negroes, mulattoes, and zambos. The whites, who are the ruling class although comparatively very few, are almost exclusively descended from the early Spanish colonists, and constitute a species of aristocracy. As a rule they have preserved their European blood in tolerable purity, although here and there coarse black hair, particularly among the females, reveals the Indian element. They are shrewd, intelligent, generous, hospitable, and distinguished by extreme suavity of manner, but are averse to every species of manual labor. The few white creoles engaged in commerce or industrial pursuits are infected with a mutual distrust which damps or precludes all spirit of enterprise. The Indians are divided into 11 great families, each subdivided into numerous tribes. The Quitus, by far the most numerous, are the direct descendants of one of the most civilized aboriginal races of the continent. At the time of their subjugation by the Peruvian conqueror Huayna Capac, they constituted a powerful kingdom, and had attained a considerable degree of proficiency in some of the fine arts, such as architecture and painting. The victorious inca divided the kingdom of Quito into provinces, under the charge of military governors chosen from his own army. Many modern writers confound the Quitus with the Peruvians, deceived by the similarity between the two languages. The other families are the Cayapos, Colorados, Jivaros, Záparos, Anguteros, Encabellados, Orejones (or "Big Ears," so named from their habit of distending the lobes of the ears by inserting large disks of wood), Avijiras, Santa Marias, and Cofanes. Each of these families has a language of its own, though some of them speak the *lingua general*, or Quito, and Spanish. A few of them have fixed habitations, profess Christianity, and have fairly entered upon the career of civilization, although little attention has been paid to their education. The so-called free Indians are mule drivers, guides, and the like, a very small number being engaged in industries on their own account. Yet they may be said to be the husbandmen, herdsmen, miners, and even the manufacturers of Ecuador. They weave cotton and woollen stuffs, make the far-famed jipijapa or Panama hats, manufacture quilts and carpets esteemed for brilliancy and durability of color, and produce the best earthenware on the southern continent. Their skill as engineers is attested by their rope bridges, spanning rivers and chasms; and as mariners they are noted for their rafts or *balsas*, on which they navigate

the rivers, and not unfrequently perform long sea voyages. Their dwellings are hovels, made in the lowlands of a sort of wild cane, and covered with palm-leaf; and in the highlands, of mud thatched with rushes. Slavery no longer exists nominally; but the planters hire the Indians at insufficient wages, and then grant them advances in order to have the right to retain them in virtual bondage. These Indians are called *concertados* or *gañanes*. Some of the families are independent, roaming along the banks of the great rivers E. of the Andes, subsisting by hunting and fishing; while others cultivate maize and other plants, which, with meat and a poison used on arrows, they barter for tools, ornaments, and other commodities. The cholos, from the union of white and Indian, number about 900,000, and constitute the chief element of the population. Here, as elsewhere, they are more comely than the pure-blooded Indians. A large portion of the retail commerce is in their hands; they are also shoemakers, tailors, carpenters, and blacksmiths, and not a few of them acquire distinction in the various liberal professions. The negroes, whose number is small, live for the most part in the seaports and along the coast; their occupations are analogous to those of their class in other American countries. Almost the entire population of Esmeraldas is composed of mulattoes. The zambos, a mixture of Indian and negro, are chiefly found in the small seaports of the north. The Ecuadorians are all fond of music and amusement. The chief pastime of the whites and cholos is bull fighting; gambling is common to all classes, and drunkenness is the besetting vice of the Indians. —The present constitution of Ecuador was framed in 1845, and has twice undergone modifications: once by the national assembly at Guayaquil in 1852, and again by the regular legislative body in 1853. The form of government is republican, and the supreme power is divided into executive, legislative, and judicial. The executive power is vested in a president, elected for four years; the present executive, however, has been elected for six years. The legislature consists of a senate and a chamber of deputies, the first composed of 18 members and the second of 30, both elected by universal suffrage. The congress assembles annually on Sept. 15, at Quito. The nomination of the president takes place indirectly by 900 electors returned for that purpose by the people. At the same time the electors appoint a vice president, who in certain cases may be called upon by congress to take the place of the president before his term of office has expired. The president is assisted by three ministers (of the interior, of foreign affairs and finance, and of the army and navy), who, with the president and vice president, are responsible to the congress. The president has no power of veto, nor can he dissolve, shorten, or prorogue the sessions of congress. The judicial power rests in a supreme and superior courts, with parochial

judges, commercial judges, and municipal alcaldes. Criminal cases only are tried by jury. Capital punishment is inflicted by shooting. There being no penitentiary, offenders are condemned to labor on public works. In trials by jury, witnesses are examined, not by the attorneys, but by the judges; and if a witness fails to appear, his original deposition may be read even in criminal cases. A petit jury consists of nine members.—Nearly one half of the revenue is derived from the customs receipts. These were in 1865, \$417,697; in 1866, \$560,916; in 1867, \$565,382; in 1868, \$567,193; in 1869, \$663,356; in 1870, \$1,037,247; and in 1871, \$1,097,151. The total revenue in 1870 amounted to \$1,451,096, and the expenditure to \$1,119,737. Through increased imposts and the undertaking of public works, the revenue for the first half of 1872 was raised to \$1,510,072, and the expenditure to \$1,446,737. By a tariff law which took effect Jan. 1, 1872, excessive duties are laid upon many of the most indispensable articles of import. Articles for agricultural and educational purposes are admitted free of duty; firearms and all commodities of war are absolutely prohibited; and the publication, introduction, and sale of books and prints offensive to religion and good morals are prohibited. The foreign debt in 1865 was \$5,634,332; the home debt \$2,214,773. For some years past Ecuador has suspended payment of both debt and interest. English bondholders in 1873 complained of this, and were assured that one fourth of the customs receipts would at an early day be applied toward the liquidation of their claims. In 1863 there were a university and 310 schools, attended by 14,000 pupils. In 1873 the number of schools was nearly doubled. An academy of arts and sciences and a school of agriculture were to be established in Quito, and the advantages of the Guayaquil normal school were to be extended to Indian children. In 1872 prospectuses were issued for a school of obstetrics and one of sculpture to be opened in Quito under the direction of European professors. The course of teaching in the primary schools embraces reading, writing, arithmetic, and religion; in the higher schools, Latin and sometimes Greek. The university course comprises the Spanish language and literature, Latin, Greek, law, medicine, &c. The income is small and the salaries of the professors very low. The established religion is the Roman Catholic, and no other is tolerated in public. There is an archbishop at Quito, and bishops at Cuenca and at Guayaquil.—After the conquest of the inca dominions (see PERU, PIZARRO, and QUITO), the kingdom of Quito was made a presidency of the viceroyalty of Peru, and remained under Spanish rule from 1533 to 1822. It was one of the most productive of the Spanish colonies. In 1809 it revolted, and after many fruitless struggles achieved its independence by the battle of Pichincha, May 22, 1822. The ter-

ritory was incorporated into the republic of Colombia, on the disruption of which in 1831 it became an independent republic under the name of Ecuador. But a series of civil wars ensued, lasting almost without intermission for more than 20 years. In 1852 a quarrel arose with Peru, whose government was accused of openly favoring a revolutionary expedition under Gen. Flores against Ecuador. Desultory hostilities continued for six years, and in 1858 Guayaquil was blockaded by sea and land. The contest was terminated in August of that year. In September, 1859, President Robles was compelled to quit the country, and in the same year Guayaquil was almost totally destroyed by fire, and Quito laid in ruins (March 22) by an earthquake. In 1862 Guayaquil again suffered from a conflagration. Several important improvements were accomplished about this time, among which were the adoption of the French metrical system, the construction of a road and later of a telegraphic line from Guayaquil to Quito, and the paving of Guayaquil and supplying it with gas and water. In consequence of the interference of Mosquera, president of New Granada, who was endeavoring to bring about the reconstruction of the Colombian republic, Ecuador declared war against him, Nov. 20, 1863. The Ecuadorian army, under Flores, was completely routed, with the loss of all its baggage, 1,500 killed, and 2,000 prisoners; these, however, Mosquera released on their promise not to serve again in that war, and signing a petition in favor of the Colombian republic. Garcia Moreno, elected president in 1861, tendered his resignation March 23, 1864; but it was refused by the assembly. An unpopular measure of Moreno's was the concluding a concordat with the see of Rome, which gave the care of public education to the priests, and restricted the toleration of creeds hitherto enjoyed. He was forced to revise and modify the measure. He assumed the dictatorship Aug. 30, 1864, and perpetrated many cruelties in his efforts for the prevention of civil war. Don Geronimo Carrion was elected president in May, 1865, and was inaugurated in August following. In January, 1866, the government joined with Peru and Chili in an alliance against Spain, and banished all Spaniards. Carrion, whose administration had become unsatisfactory to the congress, was censured, and resigned in November, 1867. Congress in its next session revoked the power of the president to imprison persons regarded as dangerous to public order, set at liberty all who were in confinement, and recalled those who had been expatriated. By a decree of Oct. 25, 1867, Bolivians, Chilians, Peruvians, and Colombians may become naturalized without a previous term of residence. Ecuador was visited in August, 1868, by one of the most awful earthquakes on record. It was especially destructive in the province of Imbabura, completely overthrowing the capital, Ibarra; 30,000 persons are said to have perished.

About the beginning of 1869, Dr. Javier Espinosa being president, the government was overthrown by a revolutionary movement under Garcia Moreno, who succeeded in establishing himself as president. One of his first acts was to order all schools to be closed except those under the control of the Jesuits. Imprisonment for debt, unless under special circumstances, was abolished. Rafael Carvajal was elected president May 16, Moreno having resigned; but the latter was reelected for a term of six years before the end of 1869.

EDDA (Icelandic, ancestress), the name of two collections of ancient poems and legends of the Northmen, or early Scandinavians, from which is chiefly derived our knowledge of Scandinavian mythology. The Eddas, and in some instances the Sagas, were composed originally in Denmark, in Sweden, and doubtless also in Norway, where the language now known as Icelandic was longest preserved on the European continent. There is no doubt that the greater part of the Edda songs were in existence before the emigration to Iceland. They are generally assigned to the 8th, and a few of them to the 9th or 10th century. Judging from the unmixed pagan spirit that pervades them, it is probable that they belong to a much earlier age, and the primitive form of the language in which they have come down to us seems to warrant this opinion. The older Edda is well known under the title of *Edda Sæmundar hins Fróða*, "The Edda of Sæmund the Learned." What has been preserved of it consists of 39 poems, collected by Sæmund Sigfússon, an Icelandic priest, who died in 1133. A copy of this Edda on vellum, the best which is preserved, was found in Iceland by Bishop Brynjulf Sveinsson in 1643, and published under the above title (3 vols., Copenhagen, 1787-1828), with an excellent *Lexicon Mythologicum* by Finn Arni Magnusson, the editor of the last volume. This copy is believed to date from the 14th century, and all the other manuscripts are more or less directly related to it. There are editions by Afzelius in Swedish (Christiania, 1818), by Munch (Christiania, 1847), and by Studach (Nuremberg, 1829). The different poems may be classed, according to the nature of their subjects, as mythological and legendary. The most remarkable in the former classification is that which bears the title *Völuspá*, the oracle of the *vala* or prophetess. It is a rapid exposition of the cosmogony of the Scandinavians, from the creation to the destruction of the universe. The *Grógaldur*, or magical song of Groa, purports to be a response to her son calling her from the grave to teach him the terms of magic. The *Vafthrúdnis-mál* narrates that Odin, desiring to test the wisdom of Vafthrúdnir, the wisest of the giants, sought his hospitality, and proposed a contest in questions and answers, the wager agreed upon being the head of the vanquished disputant. The giant recognized his guest at a question which Odin alone could put

and answer. The *Grimnis-mál* describes the 12 homes of the gods (the 12 signs of the zodiac). In the *Alviss-mál*, the dwarf Alvis goes to Thor and claims his daughter for his bride. The god agrees to give him his daughter if he will answer his questions. Alvis complies, but failing to watch for the break of day is changed into a stone. The *Hyndlu-lið* tells of Freyja, who goes with Ottar to the vala Hyndla, that she may give him an account of his genealogy. The *Háva-mál*, the sublime discourse of Odin, is a collection of maxims, ending with a chapter wherein the god explains the mysterious power of the runes against various misfortunes. The *Hymiskviða*, or song of Hymir, describes a feast given by a sea god to his brother divinities. The *Hrafnagaldur-Öðins*, the song of the raven of Odin, describes the gods lamenting the approach of their last day. The class of legendary poems in the Edda is more abundant than the other. They narrate heroic days, and record the adventures of heroes who have been more or less truly identified with Dietrich, Sigfried, and Attila and his Huns, during their first inroads upon the provinces of Rome.—The peculiarity of the verse of the Edda songs consists in alliteration and in the number of rises and falls of the voice, without regard to the number of syllables. The peculiarity of the alliteration is that different vowels are considered to effect it, and that words beginning with *sk*, *st*, *sp*, must be harmonized with other words commencing with the same two letters. A stanza of the Edda song consists either of two equal parts of four half lines or two full lines, with two rises of the voice for each half line; or of two parts, each containing a proposition, and each formed of two half lines with two, and a longer line with two to four rises of the voice.—The younger or prose Edda, also called the *Snorra-Edda*, is ascribed to the celebrated Snorri Sturlason, who was born in 1178. It is a collection of the myths of the gods, and of explanations of the versification of the scalds or poets. It was gradually formed by the labors of several writers, although it usually bears the name of Snorri Sturlason alone. It was intended for the instruction of the young scalds, and shows that the old poetry of the Icelanders came to be cultivated as a learned art. The Edda of Snorri, obviously of less value than that of Sæmund, is principally worthy of attention in so far as it completes and aids the comprehension of the other. The first copy of it was found by Arngrim Jonsson in 1628, and the first complete edition was published in Stockholm in 1818, by Prof. Rask. The work had been imperfectly known in the edition of Resenius (Copenhagen, 1665), which made a careless use of the manuscript, often confounding the text with the notes of the scalds. The introduction, or *Formáli*, is a quaint compendium of Jewish, Christian, Greek, Roman, and Icelandic legend, illustrating the origin and chain of descent of the

Scandinavian race from the heroes of Troy. The *Gylfa-ginning* follows, and relates the visit of Gylfe, a Swedish king and magician, to Asgard, in order to observe at its fountain head the spirit of northern wisdom. An English translation of the first part of the prose Edda is contained in Mallet's "Northern Antiquities" (Bishop Percy's translation, new ed., London, 1847). The second part of the prose Edda, called *Bragar hättir*, represents Bragi, the god of poetry, at a feast given by Ægir, god of the sea, entertaining the celestial company with a narration of their own exploits. The epilogue, or *Eptimarli*, written by Snorri Sturíason or by a contemporary, is an attempted solution of the Edda fables by events of the Trojan war. At the end of the prose Edda we have the *Scalda*, a kind of *ars poetica*, or manual for the use of the young students of the art. The German song of the *Nibelungen* speaks of adventures and heroes like those of the Scandinavian poems; but while the German poem was probably written about the year 1207, the Scandinavian poems are known to have been earlier, probably by several centuries.—Among the several editions and translations of the older Edda prepared in modern times stands prominent for scientific accuracy and convenience of use, H. Lüning's *Edda, Umschrift mit Anmerkungen, Glossar und Einleitung* (Zürich, 1859). The best German translation of the two Eddas is by Karl Simrock (Stuttgart, 1851), which has passed through several editions. The best French translation is by Léouzou-Leduc (Paris, 1868). Baring-Gould's "Iceland, its Scenes and Sagas" (London, 1863), gives an entertaining account of the substance of the Eddas. Eiríkr Magnússon and William Morris assert that they give in their "Story of the Volsungs and Niblungs, with certain Songs from the Elder Edda" (London, 1870), the first translation into the English language.

EDDYSTONE ROCKS, a reef in the English channel, 600 or 700 ft. long, off the coast of Cornwall, about 10 m. S. of the Rame head, entrance of Plymouth sound. They consist of three principal ridges, which are entirely covered at high water. The celebrated lighthouse on one of these rocks was begun in 1756 and finished in 1759. Its tower is 68 ft. high, and is surmounted by a lantern which is furnished with 16 powerful argand burners, with parabolic reflectors of silvered copper. The first lighthouse on these rocks was built in 1696-9, of stone and timber. It was swept away in 1703, and another tower of wood was completed six years afterward. This was burned in 1755, and the present edifice was then commenced by the celebrated engineer John Smeaton. The material employed was Portland stone, encased in granite, partly quarried from the rock itself, into which the foundations were dovetailed. The violence of the swell at the lighthouse renders communication with the shore extremely difficult even in serene weather, and

the sea frequently rises above the light, the strong plate glass of the lantern having been more than once broken by the waves.—See

Eddystone Lighthouse (with section showing the interior arrangement).

"A Narrative of the Building of Eddystone Lighthouse," by Smeaton (4to, London, 1791).

EDEN (Heb., pleasure, delight; also *gan Eden*, garden of delight), the Scriptural name of the place where God placed Adam and Eve before the fall. In the Septuagint it is called Paradise, that is, a park or pleasure garden. It was watered by a river which, issuing forth, branched into four streams, named Pison, Gihon, Hiddekel (or Tigris), and Euphrates. No locality can now be fixed for the garden of Eden. The geographical indications in the book of Genesis are too vaguely expressed to enable us to determine with any approach to certainty which locality is meant. The most probable opinion seems to be that which assigns Eden a place somewhere among the mountainous regions of Armenia, where the rivers Tigris and Euphrates take their rise. Some writers, however, are of opinion that the garden of Eden is only a figurative expression, not intended to indicate any actual locality on earth. A few years ago Sir Henry Rawlinson, in a discourse before the royal society, asserted that he had deciphered the word "Eden" in cuneiform inscriptions among the ruins of Nineveh, and that it was a name given to Babylon.—Eden is also the Scriptural name of a territory, probably in the Euphrates valley, mentioned among the conquests of the Assyrians.

EDENTATA, a small group of mammals, elevated into an order by Cuvier, and associated rather by negative than positive characters; these are, a partial or total absence of teeth, the possession of very large claws embracing

the ends of the toes, and a general slowness of motion arising from the organization of the limbs. One group consists of strictly vegetable feeders, the *tardigrada* of Illiger, including the sloths (*Bradypus*, Linn.); the other group is principally insectivorous, including the ant-eater (*Myrmecophaga*, Linn.), the armadillo (*Dasypus*, Linn.), the pangolin (*Manis*, Linn.), the aard-vark (*Orycteropus*, Geoff.), and the gigantic fossil *Megatherium*. The term *edentata*, or toothless animals, is not properly applied to any of the group except the ant-eaters and the pangolins. The sloths are fitted for a life among the branches of trees, which they rarely leave unless in search of fresh food, and then in the slowest and most awkward manner; the ant-eaters dig up their insect food with their powerful claws, and entrap them on their glutinous tongues; the armadillos, with their hard external covering, pursue insects on the ground, dig after vegetables and roots, and eat even decaying carcasses. The skull in the sloth is very short and round, in the armadillo longer and pointed, and in the ant-eater much elongated; in the *Megatherium* there is a return to the short and solid skull of the sloth, and this animal seems in many respects intermediate between the *tardigrada* and the true *edentata*. The spine varies in the length and firmness of its parts, according to the habits of the animal; the neck is long and capable of great rotation in the sloth, the two upper dorsals being so modified that they perform the functions of cervicals, with rudimentary ribs; the dorsal portion is very long, and contains more vertebrae than in any other mammalian group, viz.: 16 in the great ant-eater, 14 in the three-toed and 23 in the two-toed sloth; the ribs are remarkably broad, overlapping each other near the spine in some of the ant-eaters, giving thus great solidity to the chest and the necessary support for the digging fore limbs; the lumber vertebrae are broad, with strong spinous, transverse, and articulating processes; the caudal vertebrae are 7 or 8 in the sloths, 40 in the great ant-eater, 45 in the long-tailed pangolin, and at least 18 in the *Megatherium*; the V-shaped bones on the inferior surface are well developed in the true *edentata*, and in the *Megatherium*; the anterior bone of the sternum is considerably developed in the whole group, especially in the ant-eaters and armadillos. The pelvis in the sloths and the *Megatherium* is wide and capacious, and the ilia very broad; in the true *edentates* it is elongated, with the acetabulum behind the middle, and the ilia are very long. In the latter the anterior limbs are formed for digging, and therefore the scapular arch is well developed, the humerus short and robust, with strongly marked processes for muscular attachments; a clavicle is present in the ant-eaters and armadillos, but absent in the pangolins; the forearm has so large an olecranon that the ulna is nearly or quite twice the length of the radius; the bones are robust,

and the hand is remarkable for the unequal size of the fingers, the middle one being in most of them much the largest; the peculiarities of the posterior limbs are less remarkable. Another reason for separating the *tardigrades* from the *edentates* is found in the digestive apparatus. In the former the teeth are simple, formed for bruising leaves and stems; the stomach is complicated, divided into numerous compartments by internal folds, somewhat like the stomach of ruminants; the large intestine is readily distinguished by its size from the small, and by their partial separation. In the *edentates*, the teeth when present are simple, more numerous, and formed for crushing insects; the stomach is far less complicated, and the division into small and large intestine is not well marked. The peculiar subdivision of the arteries of the limbs in the sloths is not required in the active and terrestrial *edentates*; and the investing armor of the armadillo and the pangolin would be equally unnecessary for the arboreal *tardigrades*. The *edentata* seem to establish the passage from the *unguiculata* to the *ungulata*, as the nails are greatly developed, and cover in a great degree the ends of the fingers. That which especially characterizes them is the absence of teeth in the anterior portion of the jaws, the dental apparatus being in most reduced to molars and canines.

EDESSA. I. An ancient city of northern Mesopotamia, the capital of the district of Osroene; now Urfa, 84 m. S. W. of Diarbekir. Tradition ascribes its foundation to Nimrod, and supposes it to be on or near the site of Ur of the Chaldees. Sabaism is supposed to have been the religion of the early inhabitants, and in particular the worship of the goddess Atargatis. Under the Seleucidae it was called Callirhoë, and under Antiochus IV. it took the name of Antiochia. In 137 B. C. it became the capital of an independent kingdom. The name or title Abgar or Agbar (the mighty) appears as that of its sovereigns, and its manufactures of arms were celebrated. Edessa was sacked by Trajan, on account of the equivocal conduct of its rulers during the wars of the empire against the Armenians and Parthians. In 216 it was made a Roman military colony by Caracalla, who was murdered there in the following year. It played an important part in the early Christian church, was the residence of St. Ephraem Syrus, had famous schools of theology and more than 300 monasteries, and was for many years the principal seat of oriental learning. It was taken by the Arabs shortly after the death of Mohammed, and in the time of the first crusade became a Christian principality under Baldwin I., brother of Godfrey de Bouillon. Baldwin ruled it from 1097 to 1100, purchased Samosata and several other places, and abandoned his fief for the crown of Jerusalem. Baldwin II., cousin of the preceding, reigned from 1100 to 1118, and was called in his turn to the throne of Jerusalem. Jocelin de Courtenay, the succes-

sor of Baldwin, was surnamed the Great by reason of his victories over the Saracens. Jocelin II., who reigned after him, was defeated by the sultan Nour ed-Din, who captured Edessa and exterminated the inhabitants. It was plundered by Tamerlane in 1393, subsequently annexed to Persia, and in 1637 fell into the

hands of the Turks, who changed its name to Urfa or Orfah. The modern town is large and well built, with a wall 7 m. in circuit, and 40,000 or 50,000 inhabitants, of whom about 4,000 are Armenians, 1,000 Jacobites, and the rest Turks, Arabs, Kurds, and Jews. Its grand mosque has considerable architectural merit; within it

The Castle of Edessa.

are several schools for the instruction of young men in religion and law. Among the antiquities are the ruins of a tower said to have been the palace of Nimrod, and the catacombs in the rock beneath. It derives great commercial importance from its position on the route between Aleppo and Kurdistan. II. The ancient capital of Macedonia (probably the same as *Ægæ*, now *Vodena*), situated on a branch of the river Ludias and on the Egnatian way, at the entrance of the pass leading from the mountain provinces into upper Macedonia, and also by another branch into Pelagonia and Lyncestis. The town was the cradle of the Macedonian dynasty, and even after the removal of the seat of government to Pella, in the plains below, Edessa was still the national sanctuary and the burial place of the kings. From its commanding position it continued to be of importance under the Roman and Byzantine emperors. Taken by Basil II., the conqueror of Bulgaria, it was strongly fortified under his reign (976-1025), and was called *Bodina*, whence the modern name. The modern town, which has few remains of antiquity, is 45 m. W. by N. of Salonica. The locality is still celebrated for its scenery.

EDFOO (Coptic, *Atbo*; anc. *Apollinopolis Magna*), a city of upper Egypt, about 2 m. from the left bank of the Nile, 50 m. S. S. E. of Thebes. It has about 2,000 inhabitants, and manufactories of earthenware. Here are remarkable ruins of two temples partly covered by sand, built by the Ptolemies after the ancient Pharaonic models. The entrance

Ruins at Edfoo.

to the larger temple was by a gateway 17 ft. wide and 50 ft. high, between two truncated pyramids, 134 ft. long, 37 ft. wide at the base, and 114 ft. high. This entrance leads to a court 161 ft. long and 140 ft. wide, surrounded by walls; on each side is a row of pillars at some distance from the wall, the

space between being roofed over with stone, forming a covered portico about 35 ft. high. From the entrance to the court there is a gradual ascent to the portico of the temple, which is supported by 18 pillars in three rows, the whole height being 56 ft. Within the temple are several chambers, the last of which was the sanctuary, 33 ft. by 17, in which was placed the image of the god Num or Kneph, to whom the temple is generally supposed to have been dedicated. Champollion, however, supposed that it was dedicated to the worship of a triad, answering to the Greek Apollo, Aphrodite, and Eros. The whole is enclosed by lofty walls, and is 414 ft. long and 154 ft. wide. Every part of the temple and walls is covered with hieroglyphics, representing the daily progress of the sun through the heavens. This great structure is the most perfect example remaining of an Egyptian temple. The smaller temple, it is supposed, was dedicated to Horus, the son of Kneph; but Champollion thinks it was an adjunct of the great temple, and marks the birthplace of the third person of the triad. About three miles from Edfoo are many grottoes, excavated in the hillside, which probably served as the cemetery of the city.

EDGAR, an E. county of Illinois, bordering on Indiana; area, about 600 sq. m.; pop. in 1870, 21,450. It is drained by a branch of the Embarras river, and by Brulette and Clear creeks, affluents of the Wabash. The surface is nearly level, and occupied partly by prairies and timber. The soil is fertile. The Indianapolis and St. Louis railroad passes through it. The chief productions in 1870 were 260,643 bushels of wheat, 37,508 of rye, 2,107,615 of Indian corn, 290,679 of oats, 88,508 of potatoes, 36,638 tons of hay, 457,104 lbs. of butter, and 164,105 of wool. There were 10,294 horses, 6,666 milch cows, 20,935 other cattle, 42,786 sheep, and 38,654 swine; 3 manufactories of boots and shoes, 15 of carriages and wagons, 5 of furniture, 10 of saddlery and harness, 1 of sashes, doors, and blinds, 4 flour mills, 1 planing mill, and 3 saw mills. Capital, Paris.

EDGAR, a king of the Anglo-Saxons, son of Edmund I., born about 943, died in 975. He succeeded his brother Edwy about the beginning of 959, and made Dunstan his chief counsellor, whose influence continued paramount throughout his reign. While he was king England was disturbed neither by foreign invasions nor by the attacks of the northern pirates, and he was consequently surnamed "the Peaceful." He favored the monasteries, and especially contributed to increase the power of the Benedictines, about 50 monasteries of that order having been established during his reign. Having carried off a young lady from the convent of Wilton and made her his mistress, he was ordered by Dunstan, as a penance, to abstain for seven years from wearing his crown. His first wife was Elfrida, and his second Elfrida, the daughter of Ordgar, earl of Devonshire. William of Malmesbury, on the authority of a

Saxon ballad, relates that Edgar, having heard of the great beauty of Elfrida, sent his minister Ethelwold to ascertain whether the reports were true. Ethelwold on seeing the lady was captivated by her charms, represented to the king that she was unworthy of his admiration, and married her himself. Edgar having discovered the deceit caused Ethelwold to be put to death and married Elfrida. The story has been made the theme of an English tragedy by William Mason, and of a French opera by Guillard. He was succeeded by his son Edward II.

EDGAR ATHELING (that is, Edgar the Noble), an Anglo-Saxon prince, in the second half of the 11th century. He was the grandson of Edmund Ironside by his exiled son Edward, and was born in Hungary. In 1057 he followed his father to England, after whose sudden death in 1066 he became heir to the crown, being the nearest relative to Edward the Confessor. Yet he was young and feeble, and presented no claim, while Harold and William of Normandy fought for the kingdom at Hastings. After that battle (1066) he was received at court by William, confirmed in the earldom of Oxford, which had been granted him by Harold, and treated with the greatest kindness. He accompanied the king in his visit to Normandy, but after his return, persuaded by the discontented Northumbrian lords, he took refuge with his followers in Scotland, and sought to lead a rebellion in Northumberland. Failing in this and in other enterprises, he returned to England in 1073, having previously rendered his submission to the king and received pardon. He was afterward engaged in a Scottish war to place a relative upon the throne of that country. The best result of his career was the introduction of the superior cultivation of the south into Scotland.

EDGARTOWN, the shire town and a port of entry of Dukes co., Mass., comprising Chappaquiddick island and the E. portion of Martha's Vineyard, about 75 m. S. S. E. of Boston; pop. in 1870, 1,516. The harbor is well sheltered, and has a depth of four or five fathoms. At the entrance is a lighthouse showing a fixed light 50 ft. above the sea, erected on a pier 1,000 ft. long. Steamers run daily to Wood's Hole, the terminus of the Falmouth branch of the Cape Cod railroad, and to New Bedford. In Edgartown is Wesleyan grove, the seat of a celebrated Methodist camp meeting, at which yearly in August about 20,000 visitors assemble. Near the camp ground, on bluffs 30 ft. high, overlooking the sea, the village of Oak Bluffs has recently been laid out, and has become a summer resort; it contains several hotels and numerous cottages of summer residents. The inhabitants are mostly engaged in navigation and fishing. For the year ending June 30, 1872, 25 vessels entered at the port and 16 cleared; 4 were engaged in the whale fishery, and there were 20 registered, enrolled, and licensed. The town contains the

county buildings, a town hall, a national bank, 8 schools (including a high school), a weekly newspaper, and Baptist, Congregational, and Methodist churches.

EDGECOMBE, a N. E. county of North Carolina, watered by Tar river, and by Fishing, Sandy, and Contentny creeks; area, about 600 sq. m.; pop. in 1870, 22,970 of whom 15,112 were colored. The soil is fertile and sandy. The surface is mostly level, and occupied in part by pine forests, from which quantities of turpentine are obtained. It is traversed by the Wilmington and Weldon railroad and the Tarboro branch. The chief productions in 1870 were 6,102 bushels of wheat, 488,800 of Indian corn, 48,573 of oats, 58,055 of sweet potatoes, 3,059 tons of hay, and 18,361 bales of cotton. There were 1,164 horses, 1,919 mules and asses, 1,403 milch cows, 3,339 other cattle, and 14,214 swine; 3 manufactories of carriages and wagons, 1 of cotton goods, 5 flour mills, and 7 saw mills. Capital, Tarboro.

EDGEFIELD, a W. county of South Carolina, separated from Georgia by the Savannah river, and bounded N. by the Saluda; area, 1,540 sq. m.; pop. in 1870, 42,486, of whom 25,417 were colored. It has a fertile soil and a moderately hilly surface. Water power is abundant, and there are numerous mills and factories. The Savannah river is navigable for steamboats to the S. part of the district, and by small boats a still greater distance. It is traversed by the South Carolina, the Charlotte, Columbia, and Augusta, and the Greenville and Columbia railroads. The chief productions in 1870 were 43,157 bushels of wheat, 412,259 of Indian corn, 77,370 of oats, 29,896 of sweet potatoes, and 17,553 bales of cotton. There were 3,134 horses, 3,459 mules and asses, 6,596 milch cows, 8,579 other cattle, 6,985 sheep, and 20,352 swine; 3 manufactories of carriages and wagons, 1 of cotton goods, 1 of printing paper, 1 of bricks, and 10 saw mills. Capital, Edgefield Court House.

EDGEHILL, a high ridge in Warwickshire, England, 12 m. S. S. E. of Warwick, noted as the scene of the first battle between Charles I. and the parliamentary forces, Oct. 23, 1642. On the side of the hill is cut the colossal figure of a horse, whence a valley below has been named the Vale of Red Horse.

EDGEWORTH. **I. Richard Lovell**, a British inventor and author, born in Bath in 1744, died at Edgeworthstown, county Longford, Ireland, June 13, 1817. He belonged to an ancient Irish family, and was educated at Trinity college, Dublin, and at Oxford. While at the latter university he ran away with a young lady of Oxford, married her, and settled near Reading. He had great mechanical ingenuity, and invented various contrivances, particularly a system of telegraphs, and a locomotive machine which carried with itself a movable railway. For these he was awarded two medals by the society of arts. In 1771 he went to France, and superintended part of

the works undertaken at Lyons to alter the course of the Rhône. In 1782 he took up his residence at Edgeworthstown and devoted himself to the cultivation of his estates. He was much interested in questions of education, and brought up his eldest son upon the principles inculcated in Rousseau's *Emile*. He was also interested in political economy, and labored for the improvement of the condition of his tenants. He took an active part in public affairs, was a member of the reform convention which assembled at Dublin in 1783, and entered the Irish parliament in 1798. He was opposed to the legislative union of England and Ireland, and when the Irish parliament gave its assent to that measure, he retired from political life. In 1804 he constructed for the government a telegraph between Dublin and Galway. He was placed upon commissions to revise the laws relating to education, and to investigate the best means of draining an extensive bog in Ireland. He was married four times, the last time to Honora Sneyd, who is supposed to have been affianced to Major André. Besides various parliamentary reports, he wrote, either alone or in conjunction with his daughter, among other things, "Professional Education," "Practical Education," and an "Essay on the Construction of Roads and Carriages."—See "Memoirs of Richard Lovell Edgeworth, Esq., begun by himself and concluded by his daughter" (2 vols. 8vo, London, 1820). **II. Maria**, an English authoress, daughter of the preceding, born at Hare Hatch, near Reading, England, Jan. 1, 1767, died at Edgeworthstown, Ireland (where she had resided since 1782), May 21, 1849. She was educated by her father, and became his assistant both in business affairs and in literary pursuits. The "Early Lessons," "Parent's Assistant," and "Essay on Irish Bulls" were the fruit of their joint labors. The views which she shared with him in regard to education were exemplified in "Harry and Lucy" and "Rosamond," commenced by him and completed by her after his death, and in "Frank," written by herself. The long series of excellent novels and tales for which she was celebrated began with "Castle Rackrent" (1801). Among the most noted of them are "Belinda," "Ennui," "The Absentee," "Patronage," "Harrington," "Helen," and "Ormond." All her writings are characterized by strong good sense, practical judgment, and high moral tone. Sir Walter Scott, whom she preceded as a novelist, was her warm friend and admirer, and she passed a fortnight with him at Abbotsford in 1823. A complete edition of her works was published in London in 1832, in 18 vols. 12mo, and they still continue to be reprinted.

EDGEWORTH DE FIRMONT, Henry Allen, abbé, the last confessor of King Louis XVI. of France, cousin of Maria Edgeworth, born in Edgeworthstown, Ireland, in 1745, died in Mitau, Russia, May 22, 1807. His father (Essex Edgeworth of Fairy Mount, whence Firmont)

having been converted to Catholicism, and removed to France, he received his education under the Jesuits at Toulouse and at the Sorbonne in Paris. He was the confessor of Madame Elizabeth, the sister of Louis XVI.; and at her suggestion he was invited by him at the time of his trial and condemnation to administer the consolations of religion. He attended the king during his last days, accompanied him to the scaffold, and was reported to have exclaimed at the moment of the execution, *Louis, fils de Saint Louis, montez au ciel*. The abbé himself always professed that he had no recollection of having uttered these words, and Lord Holland has shown that they were a royalist invention, made some time later. After the death of Madame Elizabeth he joined Louis XVIII. at Blankenburg in Germany, and went with him to Mitau. While caring for French prisoners at that place, he contracted a disease which occasioned his death. He left a volume of "Memoirs," edited in English by C. S. Edgeworth (London, 1815), and in French by Dupont (Paris, 1815). A collection of his "Letters" was also published at Paris in 1818.

EDINBURGH, a city of Scotland, capital of Edinburghshire, about 2 m. S. of the frith of Forth, 357 m. N. N. W. of London by road, and 399 m. by the Great Northern railway, in lat. 55° 57' N., lon. 3° 11' W.; pop. in 1871, 196,500. It is built principally on three parallel ridges running E. and W., the central one terminated on the west by a mass of rock seven acres in extent at the top, which is 443 ft. above the sea, and upon which stands Edinburgh castle. The palace of Holyrood is at the E. end of the same ridge. Along the top of the ridge runs the principal street of the old town for the distance of a mile, its successive parts being named Castle Hill, Lawn Market, the High street, Netherbow, and Canon-gate; it contains many public buildings, and is a fine street. Upon the sides of the ridge are the ancient houses, five, six, and sometimes ten and eleven stories high, laid out in flats, in which are concentrated a great part of the poor population. Steep lanes descend from the high ground on both sides, some not more than six feet wide, and others broad enough to admit the passage of a cart or carriage; the narrower ones are called closes, and the wider ones wynds. Along the valley into which these closes and wynds descend on the south runs Cowgate, which was once a fashionable street. At its W. extremity toward the castle is an open rectangular space called the Grass market. Near the E. end rises a belt of precipitous rocks called Salisbury crags, 547 ft. above the sea, behind which is a conical hill called Arthur's Seat, 822 ft. high. The S. portion of the city is connected with the old town by two bridges over the valley: South bridge, finished in 1788, and George the Fourth's bridge, finished in 1836. It is bounded S. by a large level park, called the Meadows. The ridge on which this part of the town stands is

more elevated than that occupied by the new town, but the latter is much more handsomely built. It is N. of the castle and the High street, and separated from them by a valley, crossed by the North bridge, which is opposite the South bridge, and was opened for use in 1768, and by a broad causeway, called the Earthen Mound, which has been a thoroughfare since the commencement of the century. This valley formed for centuries a lake called the North Loch, but it was drained in 1763, and has been laid out in gardens. The laying out of the new town beyond these gardens was begun in 1767. Its streets have a regularity and magnificence in strong contrast with those of the old town. The three principal ones are Queen, George, and Princes streets, parallel with each other and with the High street. George street runs along the middle of the ridge. Princes street is between it and the High street, and is one of the finest promenades in Europe; it is built up only on one side, and commands a fine view of the castle and the old town. Queen street is N. of George street, and fronts toward the north on the Queen street gardens. The new town is adorned by many fine open squares, among which are St. Andrew square, Charlotte square, Drummond place, Moray place, the Royal Circus, &c. East of the new town is a rocky eminence called Calton hill, the broad, verdant summit

Edinburgh Castle.

of which is studded with monuments and looks out upon the frith of Forth. The new town is bounded on the north by a small stream called the Water of Leith, which empties into

the frith at Leith, the port of Edinburgh, distant 2 m. Leith is connected with Edinburgh by a spacious street called the Leith Walk.—Edinburgh castle is one of the most remarkable public buildings of the city. In former times it was called *Castrum Puellarum*, because, as it is said, the daughters of the Pictish kings resided there before their marriage. Its position upon a rugged basaltic rock, perpendicular on all sides except that next the old town, is picturesque and romantic. Its construction is irregular, and it has no great value as a fortification. It can accommodate 2,000 soldiers, and has an armory with space for 30,000 stand of arms. On its summit is a huge cannon, Mons Meg, formed of staves of wrought iron surrounded by hoops, supposed to have been constructed at Mons, Hainaut, in 1468. The regalia of Scotland, consisting of the crown, sceptre, sword of state, and treasurer's mace, are deposited in the crown room of the castle, and on the ground floor is a small apartment in which Queen Mary gave birth to James VI. The palace of Holyrood, in the E. part of the town, was the ancient residence of the Scottish kings. A part of the present structure was built in 1528, in the reign of James V. The edifice is quadrangular, with an open square in the centre, the sides of which are 94 ft. long. This palace was the residence of Mary, queen of Scots, and was the scene of Rizzio's murder. The queen's bedchamber is still shown almost exactly in the same state as when she occupied it. The largest apartment in the palace is known as the picture gallery; it contains 106 pictures which purport to be portraits of the ancient kings of Scotland. Adjoining the palace are the ruins of the abbey of Holyrood, founded by David I. in 1128. Its precincts, including Salisbury crags and Arthur's Seat, are a sanctuary within which debtors are privileged from arrest. The royal institution, one of the finest buildings of Edinburgh, built between 1823 and 1836, stands at the termination of the Earthen Mound and fronts on Princes street. It has a range of Doric pillars on each side and one in front. It belongs to the board of trustees for manufactures in Scotland, and furnishes rooms for the accommodation of the royal institution for the encouragement of fine arts in Scotland, and for other institutions. The national gallery of painting and sculpture stands upon the Mound; it is a fine building of the Ionic order of architecture. At the E. end of Princes street is the register house, a costly building 200 ft. long and 120 ft. broad, designed for the accommodation of the records of the Scottish supreme court, &c. Victoria hall, for the use of the general assembly of the church of Scotland, with its spire 241 ft. high, occupies a conspicuous position upon Castle hill.—Edinburgh is remarkable for the number of its monuments erected in honor of distinguished men. The Scott monument in Princes street is 200 ft. high. A marble statue

of Sir Walter by Steell is in its centre, and it has niches for representations of the principal characters in his writings. On Calton hill are monuments in honor of Dugald Stewart, Playfair, Nelson, and the Scotch soldiers who fell at Waterloo. On the S. side of the hill is the Burns monument, with a statue by Flaxman. Within the city are monuments also to Hume, Lord Melville, George IV., William Pitt (by Chantrey), the duke of Wellington, and others.—Edinburgh formerly consisted of a single parish, of which John Knox was for a time minister. The parish church was St. Giles's in the High street, named after the tutelary saint of the city. It is an ancient cathedral, 206 ft. long, containing three separate places of wor-

The Scott Monument.

ship, and adorned with a square tower which is surmounted by arches. They unite in the centre and support a spire which rises to the height of 161 ft. from the ground. The Tron church, so named from the tron or weighing beam which was formerly on or near its site, is in the High street at the intersection of the South bridge. The city has several other noted churches, of which three are Roman Catholic.—Among the charitable institutions, the most noted is George Heriot's hospital, founded by George Heriot, goldsmith and jeweller to James VI.; it is a fine old Elizabethan structure, designed by Inigo Jones. It is near the Grass market, on what is called High Riggs. It has a revenue of more than £17,000,

which is appropriated for the maintenance and education of children at the hospital, and for the establishment of free schools in different parts of the city. The hospital for the maintenance of poor children, erected out of funds amounting to £210,000 bequeathed by James Donaldson, printer, in 1830, is a handsome building. There are also within the city George Watson's, John Watson's, Gillespie's, and the orphan hospitals, the asylum for the blind, the deaf and dumb institution, and many other similar establishments. Edinburgh is also noted for its educational institutions. The principal of these is the university, which was chartered by James VI. in 1582. The front of the college building, 356 ft. long, is in South Bridge street. The building is of Roman architecture, heavy in design and massive in execution. There are faculties of theology, law, medicine, and the arts, with over 30 professorships. The many eminent instructors who have been employed in the medical school have given it a rank among the first in Europe. The university derives a revenue of £1,172 from foundations or bursaries, which is applied in aid of 80 poor students. The total number of matriculated students in 1872-'3 was 1,906, including 728 in medicine. Students are not required to live within the college walls, and are not subjected to discipline except when in attendance at the college. The university library contains 120,000 printed volumes and 500 volumes of MSS. The high school was founded in 1519; its present building, on the S. slope of Calton hill, was opened for use in 1829, and cost £34,000. It has a rector and four Greek and Latin masters, and the average number of students is between 400 and 500. The college founded under the auspices of the Free church is at the S. end of the Mound, and has about 500 students. There are many private medical schools of celebrity in the city which are not connected with the university. Students who attend them may obtain degrees in surgery upon examination from the royal college of surgeons. Among the other schools are the Edinburgh academy, the naval and military academy, the normal schools, Dr. Bell's schools, the Lancasterian schools, and the school of arts. The royal association has spent since its foundation £130,000 for promoting the fine arts, besides £81,000 for pictures and sculptures, and £3,000 for works to be deposited in the Scott gallery. The corner stone of the Watt institution and school of art was laid in October, 1872.—Edinburgh is the seat of the supreme courts of Scotland. The court which has supreme jurisdiction in law and equity is called the court of session, and is composed of 13 judges or lords. The court of supreme criminal jurisdiction is called the high court of justiciary. The right of pleading in the court of session belongs exclusively to an association of barristers called the faculty of advocates, and the privilege of preparing such papers and warrants as require the royal seal or signet is vested exclusively in

the writers of the signet. The judges and members of the supreme courts, including the advocates and writers of the signet, form what is called the college of justice, an institution founded by James V. in 1532. The old parliament house of Scotland is appropriated to the use of this body. It is in the heart of the old town, separated from the High street by Parliament square and the cathedral of St. Giles. Connected with it are the libraries of the writers of the signet and the faculty of advocates, both of which are extremely valuable, the latter being the finest in Scotland, and containing 150,000 volumes.—Several railways centre in Edinburgh. The Edinburgh and Glasgow, the North British, and the Granton have their termini in the valley N. of the old town, near the North bridge. The terminus of the Caledonian is in the W. part of the city, and of the Dalkeith line in the E. Through the Union canal, which connects with the Forth and Clyde canal, Edinburgh has communication with Glasgow.—On the establishment of the "Edinburgh Review" (1802) and the publication of the earlier works of Sir Walter Scott, Edinburgh began to be the seat of a large publishing business. There are about 60 printing houses, which give employment to more than 1,000 workmen. About 500 are employed in bookbinding. The manufactures of the city are not very important, but ale, shawls, carriages, and linen are made, and iron founding is carried on to some extent. The city is governed by a council of 41 members, which elects from its own number a lord provost, and six bailies, who constitute the civic magistracy. It has two representatives in parliament.—The city is supposed to have received the name of Edwin's burgh early in the 7th century, from Edwin, king of Northumbria, who is said to have made it his place of residence. The name of the place in Gaelic was Dunedin. It became a walled town and the capital of Scotland in the 15th century, when, after the murder of James I., its castle was selected as the only sufficient stronghold for the royal family and the government offices. The necessity of keeping within the walls was the cause of the houses being extended to such unusual heights. In 1513 the city was desolated by the plague. In 1544 the earl of Hertford, landing at Leith with an English army, set fire to the town, but failed to take the castle. Many conflicts took place here during the minority of James V.; one of the most violent, in which 200 men were killed, was between the Hamiltons and Douglasses, and is known in history as "clear the causeway." While John Knox was minister of Edinburgh, his preaching in 1556 gave occasion to tumults which were followed by the triumph of Protestantism. Disturbances also arose on the marriage of Queen Mary with Bothwell, and on the accession of James VI. of Scotland to the throne of England, when the union of the two kingdoms was proposed. In 1650 Cromwell, after the battle of Dunbar, took posses-

sion of the city and castle. From 1663 to 1685 large numbers of Covenanters were executed here on account of their faith. In 1736 John Porteous, captain of the city guards, ordered his men to fire upon a mob, and 6 men were killed and 11 wounded; he was tried, convicted, and condemned to death. He was reprieved by Queen Caroline, then regent, and so much indignation was aroused thereby that he was forcibly taken out of prison by another mob and hanged. This prison, the Old Tolbooth, also called the Heart of Mid-Lothian, was taken down in 1817. Sir Walter Scott introduced the breaking open of the jail by the Porteous mob into the novel which he named after it.

EDINBURGHSHIRE (formerly MID-LOTHIAN), a maritime county of Scotland, extending about 36 m. from E. to W., and 18 m. from N. to S.; area, 367 sq. m.; pop. in 1871, 328,335. Its N. boundary is formed by the frith of Forth, and is studded with important towns and havens. The S. outline is very irregular, being deeply indented by Peeblesshire, from which it is partly separated by a continuation of the Moorfoot range. These hills, the highest of which is nearly 1,900 ft. above the sea, occupy an area of nearly 50 sq. m. in the S. E. part of Edinburghshire; but many fertile dales lie hidden among them, and a great part of their acclivities is under profitable cultivation. The Pentland hills, which extend from Peeblesshire N. E. through the centre of the county, are bleak and sterile, but afford some fine scenery. The soil, except in the valleys of the Forth and N. and S. Esk, is naturally inferior, and most of the land is used for pasturage, but the farms are skilfully worked. The chief crops are wheat, barley, oats, beans, peas, potatoes, and turnips. Good breeds of sheep and cattle are reared. The minerals comprise coal, limestone, sandstone, and porphyry. The chief streams are the N. and the S. Esk, Gala Water, and Water of Leith. The county has few important manufactures, but whiskey and the famous Edinburgh ale are largely produced. The Union canal and several lines of railway terminate at the capital. The principal towns are Edinburgh, Leith, Dalkeith, Musselburgh, and Portobello.

EDISON, Thomas Alva. See p. 804.

EDISTO, a river of South Carolina, formed by the union of the N. and the S. Edisto, the former rising in the W. part of Lexington county, and the latter in Edgefield. They unite a few miles W. of Branchville, whence the course of the main stream is S. E. and S. It enters the Atlantic by two channels, between which lies Edisto island, about 20 m. S. W. of Charleston. It is navigable 100 m. from the sea.

EDMONDS, John Worth, an American lawyer, born in Hudson, N. Y., March 13, 1799, died in New York, April 5, 1874. He graduated at Union college in 1816, was admitted to the bar in 1819, and commenced practice in Hudson. In 1831 he was a member of the lower branch

of the legislature of New York, and for the four years ensuing of the senate and the court of errors. Retiring from the legislature in 1836, he was sent on special missions by the federal government among the Indians. In 1837 he resumed practice in New York. In 1843 he became one of the inspectors of the state prisons, and with the sanction of the legislature substituted for corporal coercion the system of kindness. In 1845 he was appointed one of the circuit judges of the state of New York, in 1847 was elevated to the bench of the supreme court, and in 1852 became a member of the court of appeals. At the close of 1853 he retired from the bench, and was afterward engaged in the practice of his profession in New York. Early in 1851 he began to investigate the subject of alleged intercourse with the spirits of the departed, and in the summer of 1853 made a public avowal of his belief in the same. In connection with George T. Dexter, M. D., he published a work entitled "Spiritualism" (2 vols. 8vo, New York, 1853-'5; new ed., 1865). He also published "Reports of Select Law Cases" (1868).

EDMONDSON, a central county of Kentucky, drained by Green river and Bear creek; area, 225 sq. m.; pop. in 1870, 4,459, of whom 226 were colored. The surface is hilly or moderately uneven; the soil is fertile and suitable for grass and grain. Coal is abundant, and a considerable portion of the county is occupied by beds of cavernous limestone. The famous Mammoth cave is situated here. The Louisville and Nashville railroad passes through the S. E. part. The chief productions in 1870 were 11,098 bushels of wheat, 172,998 of Indian corn, 23,684 of oats, and 414,940 lbs. of tobacco. There were 1,602 horses, 1,246 milch cows, 2,246 other cattle, 6,852 sheep, and 11,892 swine. Capital, Brownsville.

EDMUND I., a king of the Anglo-Saxons, son of Edward the Elder, and successor of Athelstan, born about 922, ascended the throne Oct. 27, 941, and died May 26, 946. Immediately after his accession Aulaf, the Northumbrian prince, invaded Mercia, and was victorious at Tamworth and Leicester. Edmund concluded a peace with him, surrendering all England north of Watling street. Aulaf died the following year, and Edmund recovered Northumbria, and subsequently conquered Cumbria, and conferred it on Malcolm, king of Scotland, on condition that he should do homage for it, and protect the north from all future incursions of the Danes. As Edmund was celebrating a festival in Gloucestershire, he perceived Leof, a noted outlaw whom he had sentenced to banishment, enter the hall and seat himself at the royal table. Edmund turned to seize the ruffian, who stabbed him fatally in the breast. He was succeeded by his brother Edred.

EDMUND II., surnamed Ironside, a king of the Anglo-Saxons, son and successor of Ethelred II., born in 989, ascended the throne in 1016, and died the same year. Even before his

accession he was recognized as the champion of the English cause against the Danes under Canute, but his abilities and hardy valor were unable to prevent the subjugation of the kingdom. Canute was proclaimed at Southampton at the same time that Edmund was recognized by the burgesses of London, which was immediately besieged by the Danes. Edmund fled, raised an army in Wessex, and at Scoerston in Gloucestershire gave battle to Canute, who was assisted by many disaffected English nobles and prelates under Edric. The battle raged for two days, and fortune seemed to have declared for Edmund, when a stratagem of Edric made the victory undecided. He again met his enemies at Brentford and at Otford; but by the perfidy of Edric, who had joined Edmund, and fled with his division at the onset, he sustained a decisive discomfiture at Assington. Edmund was prepared to meet Canute with a new army, when both the Danish and English troops, wearied of the strife, obliged their kings to compromise by dividing the kingdom. Mercia and Northumbria were the portion of Canute, and the southern parts were left to Edmund, with the provision that on the death of either the survivor should succeed to the entire kingdom. He is believed to have been murdered at Oxford, thus making way for the accession of Canute.

EDMUNDS, a S. E. central county of Dakota, recently formed; area, about 900 sq. m. The E. portion is drained by branches of the Dakota or James river. The surface is mostly table land. The greater part of the county is occupied by the Plateau du Coteau du Missouri.

EDMUNDS, George Franklin. See p. 806.

EDOM, or *Idumæa*, the ancient name of a region intervening between Palestine and Egypt. The book of Genesis describes it as the field or land of Edom. The word signifies red, and probably refers to the color of the mountain range. It was previously called Mount Seir, signifying rugged. Most of the tract is a rocky desert; but there is a considerable amount of soil that admits of cultivation, and vegetation enough for the maintenance of numbers of camels, goats, and sheep. The plain rises gently from the Dead sea to an imperceptible watershed, about 14 m. from the wady Ghurundel. Adjoining the Arabah are low calcareous hills, which are succeeded by a range of igneous rocks, chiefly porphyry, overlaid with red sandstone, reaching the height of 2,000 ft. Further E. is a range of limestone, 1,000 ft. higher, which sinks down into the plateau of the Arabian desert. The principal part of the country was that situated between the Dead sea and the gulf of Akabah; the limits and extent of the whole, however, are not precisely ascertained.—According to the Biblical narrative, Esau took possession of this land immediately after the death of Isaac; and when his descendants increased they extirpated the Horites, the original inhabitants. (See *HORITES*.) Eliphaz, Esau's oldest son, was the father of Am-

alek, whose descendants took possession of the desert et-Tih, which was afterward absorbed by the Edomites. The Edomites were at first divided into ten tribes, and some of these adopted subsequently an elective monarchy, while those of Mount Seir preserved their patriarchal organization. The list of the kings given in Genesis contains but eight names, and therefore does not carry us back more than two centuries before the exodus. The king of Edom refused the Hebrews permission to pass through his territory, and forced Moses to march round the edge of the desert, and turn the kingdom of Moab, to arrive at the Jordan. The power of the kings was subsequently extended over all divisions of the Edomites, and after the time of Gideon even over the remnant of the Midianites. After the settlement of the Hebrews the Edomites were constantly at war with them. Saul fought against them successfully, and David defeated them completely, and placed garrisons in their towns. Hadad, an Edomite prince, excited a rebellion against Solomon, which was suppressed. The Edomites remained thereafter a dependency of Judah, and revolting with the Moabites under Jehoshaphat, they sustained great losses without gaining their object. They were more successful in the time of Joram, and were once more ruled by their own kings. Amaziah defeated them in the Salt valley and took the city of Sela (afterward called Petra by the Greeks), the capital of the new Edomite monarchy. The Edomites regained their independence during the reign of Ahaz by the help of Rezin, king of Syria, and Pekah, king of Israel, and laid waste the southern portion of Judah. The first king of the new monarchy is supposed to be the Kadumalka mentioned by the Assyrian king Tiglath-pileser II. as one of his tributaries. The Edomites continued dependent upon Assyria until the time of Nabopolassar, when Necho, king of Egypt, overran the whole of Syria, and took his share of the spoils of the Assyrian empire. After the defeat of the Egyptians by Nebuchadnezzar the Edomites were incorporated in the Chaldean empire. About this time the name Edomite begins gradually to disappear, and in its stead is found the hitherto unknown word Nabathean. This is ascribed by some to an internal revolution, a change of the royal race and of the dominant tribe, of which we have no record. The monuments of Asshur-bani-pal (about 660) are the first that speak of the "country of the Nabatheans." In 590 these Nabatheans, or Edomites, joined with the Moabites, Ammonites, and Tyrians in the revolt of Zedekiah, king of Judah, against Nebuchadnezzar, which proved fatal, and drew upon them a complete devastation of their country and their capital Sela or Petra. They soon recovered from its effects, and their trade regained even a greater activity, for the complete ruin of Tyre rendered Petra the chief station for caravans from southern Arabia and the great market of the produce

of India. Their prosperity increased under the Persian kings, whose supremacy they peaceably acknowledged, and long survived the fall of Persia. After the time of Alexander the Great the Nabatheans formed an independent kingdom, which was often at war with the Jews. The prince of the latter, John Hyrcanus, annexed most of Idumæa. The Romans absorbed it under Trajan. Herod, who reigned in the time of the emperor Augustus, and the emperor Philip, surnamed the Arab, were Idumæans. The country was overrun by the Arabs in the 7th century, and ceased to form a distinct political division.—Besides Petra, the principal inland town was Bozrah, their ancient capital; and on the sea were the ports of Elath and Eziongeber, both of which were captured by David, and Havara, afterward called Leucecome by the Greeks. The government was a kind of tribal system, each tribe having its chief, subject to the supreme authority of the king. In the inscriptions recently found, persons are designated as scholars, doctors, and poets, revealing that they possessed some intellectual and literary culture. The monuments show that the supreme deity was Al or El, with a feminine counterpart under the name of Alath; other gods were principally the various Baalim, Baal Samim, Yarhi Baal, &c. Religious pilgrimages were very frequent, and the most important were to Wady Feiran, to Mount Serbal, and especially to Tor on the shores of the Red sea.—The history and topography of ancient Edom have recently been made subjects of careful investigation, and much important information may be found in Palmer's "Desert of the Exodus" (2 vols., London, 1872), Tristram's "Land of Moab" (London, 1872), and in "The Ordnance Survey of Sinai, with Notes, Plans, &c." (London, 1872).

EDRED, a king of the Anglo-Saxons, son of Edward the Elder, successor of his brother Edmund I., ascended the throne in 946, and died Nov. 23, 955. The two sons of Edmund being children, Edred in an assembly of the prelates and thanes was chosen king, and consecrated, in the style of his charters, to the "government of the Anglo-Saxons, Northumbrians, pagans, and Britons." Though afflicted with a lingering disease, he marched into Northumbria and quelled the turbulent Danes. In this reign St. Dunstan rose to power, and important ecclesiastical and monastic reforms were undertaken. His nephew Edwy succeeded him.

EDRISI, an Arabian geographer, supposed to be the person mentioned by historians of his nation under the name of Abu Abdallah Mohammed ben Mohammed ben Abdallah ben Edris esh-Sherif, who was a descendant of the Mussulman Edriside princes who reigned at Fez before the Fatimites, born in Ceuta in 1099, died in Sicily about 1180. He studied at Cordova, where he distinguished himself by his knowledge of cosmography, geography, philosophy, medicine, and astrology, and by his skill as a poet. After visiting Constanti-

nople, Asia Minor, Egypt, Morocco, Andalusia, France, and England, he went to Sicily on the invitation of King Roger II. He made for that prince a terrestrial globe of silver, upon which he inscribed in Arabic characters all that he knew of the various countries of the earth. To explain the globe, he compiled from the reports of travellers a treatise on geography. The globe is lost, but a complete manuscript of the geography was discovered in the royal library at Paris in 1829, of which a French translation by Jaubert appeared in 1836-'40. Several portions and abridgments of the work had been published many years before. Edrisi divides the earth into seven climates or zones, and each of these into eleven regions; and in his descriptions he adheres strictly to his scheme, without considering whether his divisions resemble those which have been traced by natural features or society. His work represents the state of geographical knowledge among the Arabs in the 12th century, and although it contains nearly as many errors as there are in Strabo, it was the source from which the western geographers derived their notions prior to the Portuguese discoveries in the 15th century.

EDUCATION (Lat. *educare*, to bring up, to instruct), the development and cultivation of the various physical, intellectual, and moral faculties. In a general sense, it comprehends all the means which contribute to this result in an individual from infancy through manhood—the agencies by which the faculties of the mind are drawn out, its powers disciplined, and knowledge acquired; embracing the arrangements and contrivances for the better nursing, training, and rearing of children, their physical and mental development, their nourishment, cradles, nurseries, gardens, games, and amusements; schools of every grade, from the kindergarten to the university, including special, technical, and professional schools, together with school architecture and all apparatus, means, and methods of instruction, and institutions for the instruction of every class of society, the blind, deaf and dumb, insane, idiotic, vicious, criminal, &c.; besides the instruction afforded through literature, the pulpit, and educational societies. "Education," says Paley, "in the most extensive sense of the word, may comprehend every preparation that is made in our youth for the sequel of our lives." Without treating the subject in its broadest sense, or in its strictly metaphysical relations, and without dwelling upon the various theories and speculations that have been advanced concerning education by philosophers and educators, the aim of this article will be to treat generally of the system and condition of education in the principal countries of the world, as represented by their public schools and other institutions for instruction. Details and statistics will be found in the articles devoted to the separate countries, states, and institutions of learning, as

well as separate articles on the various subjects comprised under the general head of education, such as BLIND, COLLEGE, COMMON SCHOOLS, DEAF AND DUMB, GYMNASIUM, IDIOCY, INSANITY, INFANT SCHOOLS, MILITARY SCHOOLS, NORMAL SCHOOLS, and UNIVERSITY.—In the earliest ages the entire education and culture of the people were in the hands of priests, who were the first founders of institutions, the first savants, statesmen, judges, physicians, astronomers, and architects; and science has been separated from religion, and teaching has been a distinct profession, only in the most highly civilized communities. Even in these, learning and schools have often been to a greater or less extent, more or less directly, under the patronage and care of religious bodies, since religion has been esteemed by all nations the highest interest of society. Historians usually account the inhabitants of India the most highly educated of the ancient nations of the East. Yet Hindoo learning and science have always been almost exclusively in the hands of the caste of Brahmans, who are allowed to explain the Vedas or sacred books only to the two castes next in rank. The early culture of the Egyptians was such, that the Greeks derived from them their first lessons in science and philosophy. In Egypt, too, the Israelites obtained the knowledge which enabled them to measure and “divide the land.” Public education existed only in the castes of priests and warriors, until it became more general after the rise of the Persian and Greek dominion. While the mass of the people were trained to the mechanical arts, a few only were instructed in the mathematical sciences, and in the doctrines of morality and religion.—The theocratic constitution of the Hebrew nation, and the founding of its politics and ethics on religion, produced a mental cultivation as manifested in its literature very unlike that found among any other oriental people. The schools of the prophets are the only schools which are mentioned, but children were generally instructed by their parents in the law of Moses and the history of the nation. The obedience of children to the commands of their parents is a frequent injunction in the Scriptures. Girls were taught to sing, to play upon musical instruments, and to dance on solemn occasions; and many female poets and learned women figure in the history of the ancient Jews. After the exile the rabbis established schools to which children were sent from their 5th or 6th year, and in which, besides the teaching of the Scriptures, the commentaries and traditions, the Mishnah and Gemara, were taught and committed to memory. The instruction was oral, no student ever taking notes, and the Mishnah had long been transmitted from master to pupil before it was committed to writing. The most celebrated of the early rabbinical schools were those of Jamnia (long under the direction of Gamaliel, and at which Saint Paul studied), Tiberias,

Alexandria, Babylon, and Jerusalem. During the greater part of the middle ages Jewish astronomers, physicians, poets, and philosophers were scattered through the cities of northern Africa and western Asia, Spain, Italy, and France. Their greatest schools flourished in Babylonia, Egypt, Fez, Andalusia, and Languedoc.—The culture of the ancient Persians was the exclusive care of the magi, a priestly caste of Median origin, who were the savants of the empire, the legislators, judges, interpreters of dreams, astrologers, and highest functionaries at court. There was no general system of national education, but the instruction was simple for the people, learned and religious for the magi, and military and political for the warrior. According to Herodotus, “they instructed their boys from their 5th to their 20th year in three things alone, to ride, to draw the bow, and to speak the truth.”—In Greece, boys at the age of six years passed from the exclusive care of their mothers, who educated them till then along with the girls. At about their 8th year the boys were intrusted to the care of a pedagogue, who accompanied them to school, and kept them constantly under surveillance. The schools were under the supervision but not the patronage of the state, and the fees received from pupils constituted the schoolmaster's income. Instruction began in the early morning, and was in three branches: the letters (comprehending reading, writing, and arithmetic), music (including also literature and art), and gymnastic exercises. Having learned to read, the boy was made familiar with the works of the poets, and required to commit to memory long select passages. Attendance at school was continued till the 16th or 18th year, after which those who wished became disciples of teachers of a higher order, the philosophers, rhetoricians, and sophists. For girls there were neither educational institutions nor private teachers. It was in obedience to the principles of the code of Solon that Athens became the centre and mother of liberal culture. Though education, like religion, was recognized as a part of the political constitution, yet the state left it to parental interests and affection to educate the young, ordaining only certain general rules, chiefly in behalf of morality. Thus every citizen, under a severe penalty, was required to teach his son to read and to swim; he was also to fit him for some occupation, otherwise the son would not be obliged to support him in his old age. Intellectual and æsthetic culture was always prominent in Athenian education, and gymnastic training was encouraged as much in the interest of physical beauty as of physical strength.—The Hellenic methods of education were in most respects copied by the Romans, who, however, at first laid greater stress on vigorous corporeal exercises and the encouragement of patriotism. The ancient title of the schoolmaster was master of the games (*ludi*

magister), and instruction was entirely independent of the state till near the time of the emperors. Under the empire the Greek literature was taught to the sons of the wealthy as carefully as the Latin, and the education was completed by rhetoricians, who in the time of Quintilian often received a salary from the public treasury. Athens, where there was an academy with 10 professors, was much frequented by the young Romans, and a school of high repute was founded in Constantinople by Constantine and reorganized by Theodosius the Younger. Girls were often carefully educated during the latter period of the empire; and from about the close of the republic there appear to have been schools designed for them exclusively, where they were rarely visited by their fathers.—The early Christians, unable to found separate schools for the education of their children, either instructed them at home or sent them to pagan schools. The most flourishing of these schools in the 2d century was that of Alexandria, where a multitude of pagans, Jews, and Christians prosecuted their studies together. By the side of this ancient institution soon arose the Christian school of the catechists, said to have been founded by Pantaenus in 181, in which Christian theology assumed a regular and scientific form. Similar schools were soon established at Cæsarea, Antioch, Edessa, &c. In the West there were till the 5th century pagan schools in the largest cities, as Carthage, Rome, Milan, Treves, Marseilles, and Lyons; and owing to the paucity of the Christian institutions, it was common for distinguished doctors of the church to assemble around them the young men who purposed entering the priesthood, and to instruct them by their conversation rather than by regular lessons. Early in the 5th century learning found a refuge in the monasteries, which had been introduced in the East for purposes of solitude and contemplation, but in the West for quiet and union amid the disorders of society. In the 6th and 7th centuries the schools were of three classes, the parochial, the cathedral or episcopal, and the cloistral or conventual. The Irish monasteries at this time surpassed all others in maintaining the traditions of learning. The course of seven sciences or liberal arts, divided into the trivium (grammar, dialectics, and rhetoric) and the quadrivium (arithmetic, geometry, astronomy, and music), was introduced in the 6th century, and defined in two jargon hexameters:

Gramm. loquitur; Dia. vera docet; Rhet. verba colorat;
Mus. cantit; Ar. numerat; Geo. ponderat; Ast. colit astr.

The 7th century, says Hallam, was the nadir of the human mind in Europe, and its movement in advance began with Charlemagne before the close of the next. This monarch invited to his court Alcuin from the cloisters of York, Clement from Ireland, and Theodulf from Germany, and reestablished the palatial

school, in which the sons of some of the nobility were educated with his own children, and which accompanied him wherever he went. In this school (called the palatine academy), and afterward in those of Tours and Fulda, the course of instruction embraced all the learning of the age. He also founded schools in every bishopric and monastery, in which reading, singing, computation, grammar, and the learning of psalms by heart were the exercises. Less than a century after Charlemagne, King Alfred revived letters and schools in England, which had been almost extinguished by the Danish invasion, rich libraries having disappeared in the pillage of churches and convents. At his accession Wessex could not boast a single person able to translate a Latin book. He invited to his court the most celebrated scholars, established schools in different parts of his kingdom, and ordained that the children of every free man whose circumstances would allow it should acquire the arts of reading and writing, and that those designed for civil or ecclesiastical offices should be instructed in the Latin language. Yet his efforts in behalf of learning were as unfruitful after his death as those of Charlemagne had been in France, and were succeeded by the mental torpor of the 10th century, in which, it has been remarked, no heresies appeared. As learning in that age was chiefly contained in a dead language in all the countries of Europe, it did not reach the mass of the people; the art of writing was so rare among laymen even of the higher ranks, that it was called the clerical art. In the 10th century, the darkest period of Christian literature, the Arabs had flourishing schools of learning from Bagdad to Cordova. Of their 17 universities, that of Cordova enjoyed the highest reputation, and is said to have possessed a library of 600,000 volumes. Grammar, the art of versifying, history, geography, astronomy and astrology, chemistry and alchemy, mathematics, and medicine were all studied; and in the last two departments the Arabians made important improvements on their Greek masters. An elementary school was attached to every mosque, in which reading and writing were taught, the pupils at the same time learning many poems by heart. The universities were chiefly occupied with theology, jurisprudence, and speculative philosophy; and for the natural sciences there were special schools, while medicine was taught in hospitals. The rise of the scholastic philosophy and of the troubadour poetry, the institution of universities, and the return to a profound study of the Greek and Latin classics, were the literary steps during and after the 11th century which preceded the revival of learning in the 14th and 15th centuries.—From the 12th and 13th centuries, the era of the schoolmen, date 20 universities, including those of Paris, Montpellier, Oxford, Cambridge, Bologna, Padua, Rome, Salamanca, and Lisbon. That of Bologna was especially famous for its revival

of the civil law, and attracted lawyers and students in large numbers to northern Italy from remote parts of Europe. Paris was unrivalled in the department of theology, and Montpellier in that of medicine. During the period preceding the revival of learning female education declined. Only a few schools were maintained in the large cities for the instruction of girls in reading, and the inmates of convents were taught hardly more than to repeat their prayers and to practise embroidery and other needlework. When the Byzantine empire approached its fall, the Greek scholars who had there preserved some acquaintance with ancient learning took refuge in Italy, where the love of letters had been already awakened by the genius of Dante, Petrarch, and Boccaccio, and where industrious scholars under the patronage of princes were devoting their lives to the recovery of manuscripts and the revival of philology. From Italy the more profound study of classical authors passed to the other countries of Europe, and a contest was long maintained between the scholastic and the anti-scholastic studies; between the Aristotelians, who included the most learned ecclesiastics, and the Platonists, to whom were attached most of the cultivators of polite literature. Agricola in Germany, Valla in Italy, and above all Ramus in France, wrote against scholasticism. It was assailed by the reformers and defended by the Jesuits, and is still in honor in some of the Spanish universities. Purbach, Regiomontanus, and Nicholas Cusanus were the first to promote the study of the higher mathematics. Nicholas de Clemangis and Gregorius Tifernas revived the classical taste in France, Vitelli and Coilet in England, Lebriza in Spain, and Reuchlin in Germany. The pious "Brethren of the Common Life," whose first school was founded by Gerard Groot at Deventer in 1376, also exerted a wide influence. Their schools were extended throughout the Netherlands and Germany, were distinguished alike for piety and solid acquirements, and attracted students even from Italy. In Brabant the university of Louvain was the centre of a wide intellectual culture, and the *alma mater* of many celebrities. Its European reputation increased till in 1570 it had 8,000 students. The golden age of the literature of the Spanish Netherlands was that of Albert and Isabella in the first quarter of the 17th century, in which the triumph of the renaissance was completed.—Education and the doctrines concerning it played an important part in the movements of the Protestant reformers, and also in the reaction in favor of the papacy under the Jesuits. The revival of intellectual culture among the people was associated in the mind of Luther with religious reform, and in 1528 with the aid of Melancthon he drew up the plan of studies which was followed in the Protestant common schools of Germany till the close of the century. The first class learned to read, to repeat from memory a few distichs, to write, and to

sing, and began the study of Latin. The second class studied Latin, grammar, and music for an hour daily, read and interpreted the fables of Æsop, the *Pædologia* of Mosellanus, and the colloquies of Erasmus, and committed to memory parts of Terence and Plautus, and some of the psalms and other portions of Scripture. The third class advanced to the Latin poets, and to exercises in dialectics and rhetoric, and were required to speak in Latin, and to write an exercise in that language weekly. Luther also assailed the Aristotelianism and scholastic methods which prevailed in the universities, and recommended the establishment of libraries in every town. Education was in like manner encouraged by Zwingli and Calvin, the latter of whom caused the erection of a splendid edifice for the gymnasium of Geneva, to which eight distinguished professors of Hebrew, Greek, philosophy, and theology were invited. About this time the gymnasium of Strasburg under Johann Sturm became the most flourishing of the age, and in 1578 it had more than 1,000 students, 300 of whom were of noble or princely birth. The Protestants having awakened a zeal for learning, the Jesuits determined to avail themselves of this zeal in the interest of the Catholic church, and to combat the reformation with its own weapon. They cultivated to the highest possible degree all departments of science, and employed the authority of learning in favor of the pontifical power. From Cologne, Ingolstadt, and Vienna they spread between 1550 and 1560 throughout Germany. Opposed in France by the Sorbonne, the university, and the parliaments, they did not establish their first school in Paris till 1665; but in 1750 they had won from the ancient Benedictines their pedagogic laurels, and possessed in France 669 schools, which were attended by the children of the princes and nobles.—Between the latter part of the 17th and the close of the 18th century, four distinct theories and methods of the pedagogic art arose, which are usually named the pietistic school, the humanistic school, the philanthropic school, and the eclectic school. Jansenius in the Netherlands, the Wesleys in England, and especially Spener and Francke in Germany, were the first representatives of the pietistic tendency. Spener was the teacher of Francke, who established a school at Halle for children of both sexes, and another for teachers, on the principle that religious and moral instruction should be made more prominent than intellectual acquirements, that the end of education should be a living knowledge of God and of pure Christianity. It was succeeded by similar schools in many other cities. In Greek the New Testament was the only text book. Hebrew was one of the studies of the regular course, and a change of heart was declared essential to successful scholarship. The humanistic school maintained the principle that the ancient languages and literature, especially the Greek and Latin (which were termed the

humanities), should be the foundation of education, and should be exclusively studied till the pupil went to the university. Basedow, Campe, and Salzmann were the foremost representatives of the school which made philanthropy the aim of all education, and conformity to nature its basis. Under the name of eclectics are classed those who were the disciples of no exclusive school, but from truly philanthropic motives sought to instruct classes hitherto neglected. Such was the origin of the efforts for the instruction of deaf mutes by Heinicke, Braidwood, the abbé de l'Épée, and Sicard; the instruction of the blind by Valentin Haüy, Klein, and Lenne; the institution of Sunday schools by Robert Raikes, Oberlin, and others; the organization of reformatories by Odescalchi and Tata Giovanni in Rome, and by the philanthropic society in London; and many of the special schools of commerce, agriculture, mines, the arts of design, and other departments.—In Germany since the latter part of the last century the principles of education have been actively discussed, the most prominent writers on the subject, besides some who have been already mentioned, being Sulzer, Miller, Weisse, Ehlers, Büsch, Feder, Resewitz, Gurlitt, Funk, Heusinger, Niemeyer, Schwartz, and Beneke. But the man who for the last hundred years has exerted the greatest influence on education is the Swiss Pestalozzi. According to the principles developed by him in various writings, education must begin early, under the discipline of home and the direction of parental wisdom and power. It must proceed according to the laws of nature, slowly and uninterruptedly, the teacher exciting the child to activity and rendering him but a limited amount of assistance. Individuality must be held sacred, and carefully studied and encouraged. Verbal teaching is futile unless it be implanted on previous mental experiences and verified by the senses. A development by merely mental operations, which the Socratic method favors, is vain and harmful, for the child can only utter a judgment concerning an object when he has examined it experimentally, and learned precisely to distinguish its qualities and attributes by words. Form, number, and language are the elements of knowledge, the principles by which the mind must be developed; and a thorough acquaintance with them in the various departments of learning constitutes an education. Therefore mental arithmetic, geometry, and the arts of drawing and modelling objects of beauty, are as important exercises as the study of languages. The school should be a place of liveliness and activity, and the scholar should have opportunity to exercise and reveal his power. The system of Pestalozzi has been adopted in the Prussian schools with slight modifications, and has exerted a greater influence than any other on teachers in England, America, and the north of Europe. His system was modified by Fellenberg in his institution

at Hofwyl, by Jacotot in the university of Louvain, and by Felbiger, bishop of Sagan, in the schools which he organized. There were combined at Hofwyl an agricultural institute, theoretical and practical, a rural school for the poor, a superior school for the sons of the nobility, an intermediate school for those of the middle classes, and a normal school for the instruction of the teachers of the canton. To Fröbel, the founder of the kindergarten, also belongs high honor for his reform in the principles of education.—While secondary schools have a long history, public elementary schools for the poor are of modern origin. Although government regulations concerning schools had long existed in Prussia, the present system of that country may be said to date from 1794, when the general common law (*allgemeines Landrecht*), which was prepared by order of Frederick the Great and promulgated under his successor, declared all public schools and institutions of learning to be under the supervision of the state, and established regulations for their support, management, inspection, appointment of teachers, obligatory attendance of pupils, &c. By the same order it was declared that teachers in "the gymnasia and other higher schools have the character of state functionaries." The constitution of 1850 declared that "all public and private establishments are under the supervision of authorities named by the state." National education in France may be said to date from 1833. Prior to that time many institutions for secondary, superior, and the highest culture had been liberally supported, but the educational wants of the masses had been greatly neglected. In 1831, when Guizot was minister of public instruction, Victor Cousin was sent to Prussia to study and report upon the educational system of that country. As a result of this mission a new school law for France was passed in 1833, many features of which still remain. In England until recently the establishment and maintenance of schools have been left entirely to the people. In 1834 the government began to make grants in aid of schools, and in 1839 a committee of the privy council on education was constituted for the distribution of the money. The most important step toward governmental control of education was made in 1870, when grants were authorized for the maintenance of elementary schools and their partial supervision by the government. For a more detailed statement of the historical development of national education, see COMMON SCHOOLS.—In all civilized countries education has come to be regarded by the government as a leading force not only in producing the best results in public intelligence, virtue, and citizenship, but also in developing the physical strength, as seen in war, and the material prosperity of the nation, attended with a corresponding increase of the national wealth. This is attested by the advantage gained in agriculture, commerce, industry, and skilled

labor in general, by those nations in which schools of agriculture, commerce, the arts and trades, and other special schools have received their highest development. The superiority of the Prussian arms has been attributed not only to the military organization and discipline of that country, but also in a large measure to its magnificent system of civil education. On maps showing the distribution of wealth and illiteracy in the United States, the maximum of the former is generally found in those sections where the minimum of the latter exists. And so the wisest statesmen and publicists have found that the best way to diminish the crime and pauperism of a community is to lessen its ignorance. Dr. Wines reported in 1869 that 95 per cent. of the convicts in France were illiterate, 34 per cent. in the English county or borough prisons, 49 per cent. in Belgium, 83 per cent. in Switzerland, 40 per cent. in Italy, and 35 to 38 per cent. in the Netherlands; while in the United States the percentage is about 22 of the totally ignorant and about 50 of the very deficient. Mr. E. D. Mansfield, in discussing the relation between crime and education (in the report of the United States bureau of education for 1872), concludes: "First, that one third of all criminals are totally uneducated, and that four fifths are practically uneducated; secondly, that the proportion of criminals from the illiterate classes is at least tenfold as great as the proportion from those having some education." According to the same authority, about 60 per cent. of paupers in the United States are totally ignorant, and about 13 per cent. of illiterates are paupers. "In other words, the proportion of paupers among the illiterates is 16 times as great as among those of common education." Dr. Jarvis of Massachusetts has shown that an important relation exists between education and health. Dividing the marriages for a given period in England into classes, in the first of which from 20 to 30 per cent. of the women were illiterate and in the second from 60 to 70 per cent., he found that 14.65 per cent. of the children born in the first class died under one year old, and 24.87 per cent. of those in the second. These and other considerations have recently led to a fuller recognition of the right and duty of the state to provide for public education. Hence in France, Russia, Italy, Great Britain, the United States and other countries, radical reforms in the system of education have been introduced or agitated, and the plan of compulsory education for all children of school age has been widely extended and is still undergoing a rapid growth. In Prussia, as early as 1763, a decree of Frederick the Great required parents to send their children to school, a duty which is still enforced by admonitions, reprimands, and fines. Obligatory attendance is a prominent feature of the educational system of Austria, Italy, Switzerland (except in the four small cantons of Geneva, Schwytz, Uri, and

Unterwalden), Denmark, Norway, Sweden, and other European states. The new school law of England simply permits the school boards to enforce attendance of children between the ages of 5 and 13 years; while in France compulsory education is among the reforms agitated. In the United States provision is made for compulsory school attendance in the constitutions of several states. In some states laws to this effect are now in force, while in numerous others the highest officers of public instruction have urged the necessity of such laws. Educators have usually classified general education into three grades, primary, secondary, and superior; and the schools of all countries have been arranged correspondingly. The lines of separation, however, are not drawn with precision, and the classification varies in different countries. Thus in Europe the primary division embraces the lower grades of schools; the secondary, the colleges, gymnasia, and *Realschulen*; and the superior the universities. In the United States, the primary division embraces the lowest grade of schools; the secondary, the academies and high schools; and the superior, the higher institutions of learning, such as colleges. Some authorities regard colleges as within the second class, and assume that there is no provision for superior education in this country. Outside of these grades is the special education afforded in all countries by the professional and technical schools. Perhaps a more satisfactory classification would be: 1, elementary schools, including common schools, evening schools, and schools for the blind, deaf and dumb, and idiots; 2, middle schools, comprising colleges, gymnasia, realschulen, &c.; 3, professional and technical schools; 4, universities.—The plan of public instruction in Prussia, which also prevails generally throughout the German states, has long been preëminent as the most complete system of national education yet developed. The cardinal features of this system are: 1, the right and duty of the state to establish a sufficient number of elementary schools for all children of school age; 2, the obligatory attendance of every child between the ages of 7 and 14 years at some elementary school, public or private; 3, the special preparation of teachers, as far as practicable, for every grade of school, with opportunities for professional improvement and promotion, and guaranty of pecuniary aid when sick, infirm, or aged, and for their families in case of death; 4, a system of inspection, intelligent, frequent, constant, and responsible, reaching every school and every teacher. The superintendence over all institutions of instruction, private and public, belongs to the state. Formerly the supervision of the schools in the lower grade was held largely by the clergy, but in 1872 a new school law was passed looking to the entire separation of school and church, and withdrawing the direction of educational matters from the clergy as such, al-

though clergymen may be and are appointed by the state as school superintendents. For political purposes the state is divided into 11 provinces, which are subdivided into 35 regencies (*Regierungsbezirken*), and these again into districts (*Kreise*) and parishes (*Gemeinden*). These divisions are also adopted for educational purposes. The supreme authority in all matters relating to education is vested in a minister of public instruction, who is appointed by the crown. Local supervision is vested in the provincial authorities, who have general control of secondary education, including the gymnasia, realschulen, and primary normal schools. Each province has a *Consistorium*, which is divided into two sections, one for ecclesiastical purposes, and the other, the *Schulcollegium*, for educational affairs. The members of the latter receive their appointment and salary from the crown. As a general rule, the administration of the school fund provided by the state, and the management of the lower and elementary schools, are exercised by the civil government of the province, while the *Schulcollegium* supervises the higher schools, the general system of instruction and discipline, the selection of text books, the examination and appointment of masters, and the examination of those who leave school for the universities. Immediately below this is the church and school section of the supreme council of the regency, presided over by the school councillor (*Schulrath*), and charged with the examination and appointment of teachers in the primary schools, with keeping the schools in good condition, and with collecting and disbursing school funds. The educational affairs of a district are intrusted to the councillor of the district (*Landrath*) and the inspector. Finally, each commune or parish must have its school, and each school its committee of supervision (*Schulvorstand*), consisting of the curate, two magistrates, from two to four notable persons of the parish, and its inspector, usually the parish clergyman. In the larger towns and cities the general management of all the schools is intrusted to a board consisting of the burgomaster (mayor), members of the municipal council, pastors, and directors of the higher schools. There is also a committee of management for each school. A complete plan of inspection exists throughout the system. Each of the heads of council, from the highest to the lowest civil division, is appointed by the government, and has the power of veto over the acts of the council, board, or committee over which he presides. Thus the entire school system is completely under the control of the general government. In case the funds arising from endowment, tuition, &c., are insufficient, the deficit is made up by local taxation. The rate of tuition is low, generally one groschen (2½ cents) a week in the villages, and from 10 silver groschen to 2½ thalers a month in the towns. Children unable to pay this amount may have the benefit of a deduction,

or be admitted entirely free. Each parish or commune must maintain its own school; if it is unable to do so, the district, the province, and the state share the expense. Attendance upon the schools is obligatory during school age, 7 to 14, and is enforced by admonitions, reprimands, and fines. A close supervision over the examination and appointment of teachers is maintained by the government, and no teacher is appointed until his moral and educational qualifications have been proved. Private schools may be opened by individuals, but they must be under state supervision, and the teachers must be examined and receive permission to teach from the government authorities. The schools of Prussia may be divided into five general classes: 1, primary; 2, burgher; 3, *Realschule*; 4, gymnasium; 5, university. Besides these there are normal schools or teachers' seminaries of three grades, and a great variety of special and professional schools devoted to instruction in the practical arts, and the application of science to industry, the liberal professions, and the fine arts. In country or smaller towns the *Volksschulen* combine the American primary and grammar schools; children enter at six years of age, and remain till their school education is completed. In the burgher schools the course of instruction covers eight years, and embraces the ordinary elementary studies, prominence being given to religious instruction, music, drawing, and gymnastics. During the first three years the sexes are taught together; afterward in separate schools, except in villages where the population is small. Generally no opportunities are offered in the public schools for the higher education of girls, except that afforded by the burgher schools; but in several of the cities schools have been organized for this purpose. Instruction in household work, handiwork, or some branch of trade, is given in the regular course, or in separate departments. The burgher schools are of several grades, the highest ranking with the American high school. The realschule has a "realistic" course (*Realia*), which differs from that of the gymnasium mainly in being less classical, and which provides a broad course of education for those intending to pursue commercial or mechanical occupations, or prepare for any of the special schools without entering the university, their object being to "prepare by scientific education for those higher vocations of life for which academic studies are not required." Realschulen are classified into those of the first rank, those of the second rank, and higher burgher schools. The ordinary studies of the realschule are German, French, English, Latin, mathematics, geography and history, natural history, physics and chemistry, mechanics, drawing, religion, singing, and turning or gymnastics. Students are usually admitted at seven years of age, and complete their studies at 15 or 16. From 32 to 34 recitations, of 50 minutes each, are required each

week. The highest secondary institution is the gymnasium, which is intended to prepare students for the university. The general plan of instruction is fixed by the state, and great prominence is given to classical studies. The course covers nine years, students being usually received at 9 or 10 and graduated at 18 or 19. The number of recitations varies each year, and ranges from 25 to 32 a week, exclusive of singing and turning. The realgymnasium has a classical and a realistic course combined. On the completion of the course in the gymnasium, a thorough examination (*Abiturienten-Examen*) is held, which the student must pass satisfactorily before obtaining the certificate (*Maturitätszeugniss*) by which alone admission to the university is secured. A marked feature of the Prussian system is the governmental supervision of university education. The universities, of which Prussia has ten, were in most cases founded by the sovereign, who endowed them with lands and money. The government retains supreme authority over these institutions, and even appoints the professors; it also provides for deficiencies in their incomes. Special officials (*Curatores*) form the connecting link between the government and the universities. The German university comprises four schools called faculties: theology, law, medicine, and philosophy. The last named comprises language and literature, the mathematical, physical, and natural sciences; in short, the whole range of knowledge as considered independent of the professions. The course of study is commonly four years. Most thorough instruction is given by means of lectures, and examinations are held for degrees. The extent of the instruction provided may be inferred from the fact that nearly 400 distinct courses of lectures, covering the entire realm of science, letters, philosophy, and religion, are given during the year at the Frederick William university in Berlin. To be qualified for a learned profession, or for employment as a teacher in the higher schools and universities, it is necessary to have completed the university course and to have graduated. In the German empire in 1873 there were 21 universities, with 1,734 professors and 18,858 students.—The classification of schools in Austria is similar to that in Prussia. The school law of 1869 provides that in every common elementary school (*allgemeine Volksschule*) at least the following subjects shall be taught: religion, language, arithmetic, the most necessary elements of natural philosophy, geography and history, with particular regard to the country and its constitution, writing, geometrical forms, singing, and gymnastics. Girls shall also be instructed in needlework and housekeeping. The plan of instruction is determined by the minister of education, on the recommendation of the provincial school boards. Religious instruction is cared for and superintended by the respective church boards. The time required

to complete the course in these schools is eight years. The obligation to attend begins with the 7th year and lasts until the 14th is completed. Parents or their substitutes, as well as the owners of factories and industrial establishments, are responsible for the attendance of children, which may be enforced. The law provides that "the obligation to establish schools shall be regulated by the provincial legislature, on the principle that a school under any circumstances must be established in every locality, where, in a circuit of one hour's walk, on an average of five years, more than 40 children can be found who have now to attend a school more distant than one hour's walk. For children in manufacturing establishments who may be prevented from attending the common school, the proprietors of such factory, &c., shall establish, either by themselves or in connection with other manufactories, separate schools of the same grade as the public schools." All schools and educational institutions founded or supported wholly or entirely by the state, by a province, or by municipalities, are accessible to all citizens of the state, without regard to creed. A well organized system of inspection extends to every grade of instruction. The institutions for secondary and superior instruction are similar to those in Prussia. Austria has 4 universities, with (1873) 443 professors and 5,382 students. The institutions devoted to education in special branches comprise theological seminaries, schools of surgery, higher commercial colleges, polytechnic schools, nautical schools, schools of midwifery, of mining, of forestry, of agriculture and horticulture, military schools, conservatories of music, academies of fine arts, and a school of industrial art.—The rigid supervision exercised by the government over education in Germany is perhaps most marked in the measures adopted to secure efficient teachers. The teacher, being trained, examined, appointed, and paid by the government, is regarded as an officer of the government. He is virtually exempt from military service, and is entitled to a pension when no longer able to teach. No person is appointed as teacher who is not in good standing in the church, Lutheran, Catholic, or Jewish. The teachers' seminaries or normal schools are of two grades, designed for the training of teachers for the lower primary schools of the rural districts, and the burgher and other higher schools of the cities. There are separate schools for males and for females. Each one consists of the professional or normal school proper and a primary model school, or school of practice. The number of pupils in each school is limited to about 70, who are admitted by competitive examination, which is open to all over 17 (in some states 18) years of age, who possess certificates as to character, health, natural aptitude, &c. Before being admitted, the candidate must sign an agreement to teach for three years after completing the course in the seminary, or to pay the whole cost of his education therein. The course of

study is usually three years, and embraces religious, intellectual, and industrial instruction. Frequent examinations are held as a test of progress. The study of music and drawing and practice in the art of teaching are more prominent features perhaps than in any other country. For a more comprehensive education of teachers special courses are established in some of the universities and technical schools, and their improvement is further provided for by means of educational journals, libraries for teachers, periodical conferences for teachers, and special courses for professional improvement. In no other country has the kindergarten been so successfully established as in Germany. This institution, originated by Fröbel, provides for the education of infants between the nursery and the school by means of plays, games, stories, conversations, singing, and other simple exercises adapted to the nature of the child. Much importance is also attached to object teaching, which is a continuation of the kindergarten, and designed especially to develop the perceptive faculties. The kindergarten has also been introduced into Italy and other continental countries and the United States. Many of the seminaries of Germany for training female teachers have departments for the preparation of teachers for the kindergarten. Another important feature of the German system is the numerous schools open evenings and Sundays for adults who are unable to attend the ordinary schools.—In France, as in Germany, every grade of public instruction is under the direct control of the government, which acts through the minister and superior council of public instruction. This council under the late empire consisted of the minister, three senators, five bishops or archbishops, three councillors of state, three members of the court of appeals, eight inspectors general, three clergymen (Lutheran, Reformed, and Jewish), five members of the institute, and two heads of private educational establishments. The schools are classified as—1, primary, including all elementary and the lowest grade of normal schools; 2, secondary, comprising the communal colleges, lyceums, and the second grade of normal schools; 3, superior, comprising the academies. To insure a high standard of excellence in the schools of every grade, a rigid system of inspection prevails. Every commune is required to establish and maintain schools for primary instruction, and is aided by the government whenever the school fees and local taxes are insufficient. Instruction in religion is given in all public schools, but no pupil is obliged to receive instruction in any creed against the wish of his parents. Private schools are encouraged, but instructors in these must pass the examinations required of those serving in the public schools; and the proficiency of their pupils and their general management are subject to governmental supervision. The lyceums are founded and maintained by the state with the coöperation of the departments and

towns, while the communal colleges are founded and maintained by the communes. The arrangement of classes and studies is fixed by the government, and is the same in both. Superior education is provided for by the academies, of which there are 15 in France proper, each constituting the educational centre of an academy district and embracing several departments of the country. These institutions correspond to the universities of other countries, though many of them are inferior to the German universities. A complete academy embraces the five faculties of sciences, letters, theology, law, and medicine. Only the academy of Paris, however, includes all these faculties. All have faculties of letters and science, six of theology, ten of law, and two of medicine. The affairs of each academy, including all superior and secondary institutions of the district properly subordinate to the minister of public instruction, are managed by an academic council. Under the empire this consisted of the rector as president, the academy inspectors (one for each department in the academic district, except in Paris, where there were eight), the heads of faculties, known as deans, and seven additional members appointed triennially by the minister, and including an archbishop or bishop of the district, two ministers of the Catholic, Protestant, or Jewish church, two magisterial officers, and two public functionaries or other notable persons of the district. The degrees conferred by all the faculties are those of bachelor, licentiate, and doctor. Besides the academies, there are numerous institutions of great excellence in France for advanced education, among which may be mentioned the *collège de France* in Paris; the *école des chartes*; the museum of natural history; the school of living oriental languages, with chairs of learned Arabic, vulgar Arabic, Persian, Turkish, Armenian, modern Greek, Hindostanee, modern Chinese, Malay and Javanese, Algerian Arabic, Thibetan, and Japanese; the school of Athens, &c. All these institutions, with the chief public libraries of Paris, are under the supervision of the minister of public instruction. In like manner the special schools are under the supervision of the different ministries. Thus the minister of war has the supervision of the polytechnic school, the military school of Saint Cyr, and the cavalry school of Saumur; the minister of marine, of the naval school and the schools of hydrography; the minister of finance, of the school of woodcraft (*école forestière*); the minister of the household, of the school of fine arts; the minister of agriculture, commerce, and public works, of the schools of agriculture, veterinary science, arts and trades, arts and manufactures, commerce, mines and miners, &c. Applicants for the position of teacher in any of the public schools of France must prove their qualifications by rigid examinations regulated by the government. The educational

system of France has recently undergone some changes, and is now in a transitional state. In 1871 Jules Simon, minister of public instruction, brought before the assembly a new school law which had been approved by the council of ministers. It made attendance upon the schools obligatory, and provided for the disfranchisement after 1880 of those electors who have not attended school, or cannot read or write. Rules were laid down for the inspection of schools and the employment of teachers. The expenses for elementary education were, in the first place, to be met by the municipalities and the departments, and aid to be granted by the general government only in extraordinary cases. In every department a teachers' seminary for males and females was to be established, supported by the government. Jules Simon having been succeeded by M. Batbie, these reforms have not been realized.—The English system of public instruction has until recently, as before mentioned, been remarkable for its complete independence of the government and want of national organization. While in Germany the organization and entire control of all schools for general instruction is assumed by the government, and in the United States all the common schools are supported and controlled by the people under the supervision of the state, and open to all classes without charge for tuition, in England these important interests have been left to individuals and corporations. Except the pauper schools and those belonging to naval, military, and penal establishments, no schools have been organized by the government, nor has their management been vested in the government. It has, however, made conditional grants in aid of popular education. These grants were of two kinds: 1, to aid in establishing schools; 2, annual grants conditional upon the attendance and proficiency of the scholars, the qualifications of the teachers, and the state of the schools. All schools receiving grants were subject to yearly examination by government inspectors. In 1870 a new school system was established by the government, which, though far from being complete, was an important improvement upon the existing one, and may lead to a comprehensive system of national instruction. This measure provides for the annual grant by parliament of a sum of money to secure the establishment and maintenance, in every school district, of public schools sufficient for the elementary instruction of all the children resident therein whose education is not otherwise provided for. This fund is administered by the department of education, at the head of which is the lord president of the council on education. Two classes of schools come within the provisions of the act: 1, elementary schools, which comprise those where the principal part of the instruction is elementary, and not including any school or department where the tuition exceeds ninepence a week; 2, training schools to qualify teachers for the elementary schools. The grant

is given annually to managers of schools, and is intended to aid voluntary local action in the establishment of new schools and the maintenance of existing ones. It is made only on certain conditions, the chief of which are that no child shall be refused admission except on reasonable grounds; sectarian religious exercises shall not be required of any pupil; certificated teachers must be employed except in the evening schools; and the schools must be open to the government inspectors. School boards, composed of not less than 5 nor more than 15 members, intrusted with seeing that the provisions of the law are complied with, are elected in boroughs by the burgesses, and in parishes not within the metropolis by the rate payers. They are permitted to enforce the attendance of children between the ages of 5 and 13 years. Special provision is made for the election of school boards in London. All school expenses are paid out of the school fund, which consists of fees, parliamentary grants, loans, &c. All children whose parents are unable to pay for their education shall be admitted free to these elementary schools. Under the new law, schools which have met not less than 400 times in the morning and afternoon during the year may claim 6s. per student, according to the average number in attendance throughout the year; for every scholar present on the day of examination who has attended not less than 150 morning and afternoon meetings, if above 4 and under 7 years of age, 8s.; or 10s., if the infants are taught in a separate department; if more than 7 years of age, 12s., subject to passing an examination in reading, writing, and arithmetic. The managers of evening schools which have met not less than 80 times during the year may claim 4s. per student, according to the average number in attendance throughout the year, and 7s. 6d. for each one who has attended not less than 50 evening sessions, subject to a successful examination in reading, writing, and arithmetic. Provision is made for the individual examination of students upon certain standards clearly defined for each grade of schools. The parliamentary grant to popular education in Great Britain was £1,093,624 in 1871, and £1,551,560 in 1872. The importance of training schools for teachers is recognized in the new school law, and government aid is extended to this class of institutions on the same conditions as to the public elementary schools. Provision is also made for training and employing "pupil teachers." A training school includes a college for boarding, lodging, and instructing candidates for teachers in the elementary schools, and a practising department to afford training in the art of teaching. Admission is by competitive examination open to all who intend to adopt teaching as a profession, and have either served the apprenticeship of pupil-teachers or are over 18 years of age. The course of study is two years. To obtain certificates teachers must be examined and must undergo probation by actual service. It will

be noticed that the above described supervision by the government applies only to the lower grade of schools in England and Wales, and only to such as choose to comply with the conditions laid down. Higher instruction is afforded by the great body of endowed schools, including grammar schools and colleges, and by the universities. In the former, which are the middle schools of England, students are fitted for the universities. They are attended largely by the wealthier classes; and the studies are chiefly classical. In England there are the universities of Oxford, Cambridge, Durham, and London; there are four in Scotland, and two in Ireland. The most famous of these are Oxford and Cambridge, which have been richly endowed by the government and by individuals. Both are corporations comprising numerous colleges (Oxford 24, Cambridge 17), each college being a distinct organization with its own governing body. Instruction is administered by tutors, and examinations are held for degrees. In 1869 a bill was passed bringing all the educational endowments of England under the supervision of the department of education. The educational interests of Ireland are under the supervision of a board of commissioners for national education; but there is no educational division of the country, and no public tax for school purposes. Parliamentary grants are made in aid of popular education on certain conditions, and a vigorous system of inspection by government commissioners prevails. The parliamentary grants for popular education amounted in 1872 to £430,390.—The Swedish system embraces the usual classes of schools. A *folk skola*, or school for the common people, is required to be maintained in each *socken* or parish, of which there are more than 2,000. Instruction is gratuitous, the schools being supported by direct government grants and local taxation. Children between the ages of 9 and 15, who are not otherwise receiving instruction, must attend these schools, under penalty of separation from their parents; but this is seldom enforced. A prominent feature in the management of these schools is the power vested in the clergy. Educational matters in a parish are controlled by the church meeting (*kyrko-stämman*), which is presided over by the pastor and composed of tax-paying parishioners who belong to the established church. Inspectors are appointed by the ecclesiastical department, on the recommendation of the bishop of the diocese in which they are to act. In the selection of teachers special regard is paid to their religious sentiments. Where fixed schools are impracticable, "ambulatory" schools have been provided for, whose teachers travel from one farm to another, instructing the children of the peasants. In the folk schools prominence is given to religious instruction (Biblical history and the catechism), drawing, singing, military exercises, and gymnastics. There are 10 higher folk schools designed to afford a

somewhat more advanced course of study to children of the common classes. The studies are proposed by the parents and teachers, and determined by the bishop and rector. The state annually appropriates 1,000 rix dollars (\$265) for each school. Tuition is gratuitous. Between the folk school and the university are the higher elementary, the lower elementary, the pedagogical schools, and the normal schools. There are 31 schools for higher elementary instruction, one or more being established in every *stift* or diocese, sustained by appropriations out of the state treasury. These institutions afford complete preparation for the university, corresponding to the gymnasia of Germany and the grammar schools of England. There are two courses of study, the classical and the practical, and seven annual classes. The power of appointing all the teachers of these schools is virtually with the bishops. Each school has a principal called the rector, who is assisted by about five lecturers or teachers, who must at least have had the degree of master of arts before appointment; there are also from seven to fifteen assistants, who must be graduates of the university, besides three or more teachers of music, drawing, military tactics, and gymnastics. Each school has an inspector who is appointed by the bishop. The usual fee paid by each pupil is about 10 rix dollars (\$2 60) for the term of eight months. The lower elementary schools differ from those above described chiefly in the number of classes. Each school has an inspector, a rector, and from one to five assistant teachers, all appointed by the bishop. A small tuition fee is paid. The pedagogical schools are inferior to the lower elementary. These are in the smaller towns, are exclusively for boys, and are supported by appropriations out of the state treasury. There are nine normal schools, seven for males and two for females. Instruction is gratuitous; the course is three years. To each is attached a school for practising the art of teaching. The private schools of Sweden are under the same inspection that the government requires for elementary schools. With the exception of one seminary and two normal schools for the training of female teachers, no provision exists for the instruction of girls beyond what is afforded in the folk schools. Sweden has two ancient and famous universities: that of Upsal, with 100 professors and tutors and about 1,500 students, and that of Lund, with 75 professors and tutors and about 500 students. In the former the course of study varies from three to six years, the faculties being the same as in the German universities. All public lectures are free. The other educational institutions of Sweden embrace folk high schools for the instruction of children and adults in business, politics, and the duties of life; an institution for the deaf, dumb, and blind in Stockholm; agricultural institutes and schools, which receive some aid from the government, but are principally self-

sustaining; an institute and schools for instruction in maintaining and stocking forests; industrial and trade schools; schools for drawing and designing; navigation schools, and an institute for ship building. The government grants aid to numerous scientific and art academies, a medical school, two veterinary institutes, a military, and a naval school.—Since 1814, when Norway regained its independence, the system of education has received careful attention, and the various reforms in it attest the democratic spirit which pervades the Norwegian institutions and constitutes their strength. Its educational institutions may be divided into five classes: 1, common schools; 2, grammar and high schools; 3, Latin schools, and combined Latin and high schools; 4, the university; 5, schools for special branches. The first class comprise common schools in the country and those in towns. The former include "lower schools," in which children belonging to a circle of the district receive instruction either voluntary or compulsory, and "higher schools," comprehending several circles or districts, in which the children receive a more complete education. The law requires that wherever there are 30 children, legally bound to attend school, living so near each other as to be able to attend the same school daily, a common school shall be established. In districts where a small population is scattered over a surface of several miles, "ambulatory schools" have been established. Where even these are impracticable, the law requires that instruction shall be provided in some other manner. The school committee is empowered to establish schools for children under the school age, which may be conducted by female teachers, and also sewing schools and other industrial schools. Manufactories and other industrial establishments are obliged to provide a school for the children of their workmen. The establishment of lower common schools is obligatory on the school districts, but that of the higher schools is optional. It is provided that there shall be at least one common school in every town. The branches of instruction in these are almost the same as in the rural schools, and embrace reading, knowledge of the Christian religion, selected parts of the reading book (which is published by the government and is the same in all these schools), chiefly such as relate to history, geography, and knowledge of nature, singing, writing, arithmetic, gymnastics, and military exercises. Attendance on the common schools 12 weeks annually is obligatory for all children living in the country, from the 8th year (in the towns from the 7th year) till the time of their confirmation, unless otherwise instructed, under penalty of fine and separation from their parents. The school committee, however, may allow the child to leave school at the age of 13, if sufficiently advanced in instruction. Once a year a public examination of the pupils in the common schools is held, in the presence

of the pastor and other members of the school committee. All children above nine years of age who are bound to attend school must take part in it, even those receiving private instruction corresponding to that of the common schools. As a rule the primary instruction is free. Each municipal district forms a school district, and has a school fund common to the several circles into which a district may be divided. The municipal council grants the money in all school matters, determines the amount of school expenditures, and apportions the school tax, which is sometimes distributed among all the families of the district, but generally assessed on the residents in proportion to their fortune. All the school districts belonging to the same province form together a higher school district and have a common fund. A normal school has been established by the government in each of the six dioceses. They are under the supervision of the government, and their teachers are appointed by the king. Connected with each normal school is a children's school to exercise the normal pupils as teachers. In addition to these, there are smaller institutes for teachers, either as parallel classes of a higher common school, or as a higher class of a public common school. The so-called higher or civic schools differ chiefly from the best arranged common schools in the addition of modern foreign languages, and in giving a fuller instruction in other branches. Some of these schools also prepare pupils for the university. They are supported by the municipalities, or at least guaranteed by the towns in case the pupils pay for their tuition. Most of them are exclusively for boys; some for both boys and girls, and two are exclusively for girls. Many of these schools are under the inspection of the superintendents of the diocese, and some are supported by the educational fund, which now amounts to more than 3,000,000 specie dollars (\$3,335,000). This fund owes its origin to the sale of large estates formerly bequeathed to the clergy and churches. The Latin schools and combined Latin and high civic schools are in the principal towns and belong to the state. They afford a higher general education, intended to prepare students by classical studies for the university, or by the study of natural sciences for practical life. The greater part of these schools are partly supported by contributions from the state and the town. The pupils pay for tuition in all of them. Until quite recently particular attention has been paid to the study of the classics, but public opinion has compelled a reduction in those studies and a proportionate increase in the study of modern languages and natural science; and the old Norse tongue and English have been made obligatory studies. The highest instruction is afforded by the university in Christiania, which has the five faculties of theology, law, medicine, history and philosophy, and mathematics and natural science, with about 50 professors and 1,000

students. The lectures are gratuitous, and the students are not bound to any fixed term of study. The special educational establishments of Norway comprise asylums for very small children in the towns and Sunday schools (for secular instruction), which are chiefly supported through private liberality; the peasants' high schools, copied from the Danish system; agricultural schools in most of the provinces, supported by the state and the various districts; nautical schools established by the government in the towns along the coast to educate captains for the commercial marine; a military college for the training of army officers, a naval school, a military high school for the education of engineers and artillery officers, and a school for engineers recently founded by the government.—In Denmark popular education has been provided for and fostered by the government for more than 300 years. The general control of this interest is vested in a minister of public instruction and subordinate superintendents for the several departments of the kingdom. Each parish is obliged to furnish good primary-school buildings, with teachers for the instruction of children in reading, writing, arithmetic, the Lutheran catechism, grammar, history, and geography. There are normal schools for the training of teachers, which add to these primary branches studies in mathematics, the natural sciences, the art of teaching, gymnastics, drawing, and music. About six years are devoted to secondary instruction, the studies being similar to those of the German gymnasium. In the four lower classes choice of studies is given to students; in the two higher the instruction is divided into two coördinate divisions, one devoted to philological and historical studies, and the other to mathematics and natural science. Old Norse, Danish, French, English, and history are taught in both divisions. More than 70 farmers' high schools (*Folkehøiskoler*) have been founded for the purpose of elevating the standard of education among the rural population and making them acquainted with the national history and literature. They are supported by private means, aided by the government. These schools have also been introduced into Sweden and Norway, where they have attracted much attention. Superior education is afforded by the university of Copenhagen, founded in 1478, which has faculties of theology, law and political science, medicine, philosophy, and mathematics and natural science. Instruction is given to more than 1,000 students by about 80 professors and docents. —In the Netherlands the plan of education is threefold: primary, embracing the elementary schools of various grades, normal schools, evening schools, &c.; secondary, including the burgher schools, agricultural, polytechnic, and navigation schools, institutions for deaf mutes and blind, schools for nurses, and schools of veterinary surgery; superior, comprising the universities, atheneums, Latin schools, and

gymnasias. There are also schools and academies for the army and navy, prison schools, and infant schools. Educational matters are under the control of the minister of the interior. The 11 provinces are divided into 89 school districts, and these into communes, in each of which there must be a primary school under the charge of a local board; and each commune of 3,000 persons has a school commission. For each district there is an overseer, who is chairman of all the commissions within his jurisdiction. At the head of the districts of each province is a provincial inspector, salaried by the state, whose duty it is to superintend all the schools in his province, receive the reports of district overseers, and once a year to sit in the council of provincial inspectors under the presidency of the minister for the consideration of the general interests of primary schools throughout the kingdom. Each commune must support a sufficient number of primary schools, or, if it is unable, the province and the state must share equally the expense. Primary schools must be open throughout the year, excepting on holidays. Attendance is not obligatory, but parents are denied aid from charitable institutions if their children have not been instructed in the elements of a popular education. An educational society has been formed, with branches all over the country, whose object is to use all moral means possible to induce parents to send their children to school. It also aims to secure the enactment of a law prohibiting the employment in factories of children below the age of 12. A regular school fee is generally paid in the private and public day schools, but in the case of poor parents an exception is made. About one half of the children attending schools are instructed free. Numerous schools for adults are maintained. There are both public and private normal schools and normal classes. There are three government normal schools; the course of instruction occupies four years, with from 39 to 44 hours a week. In all the provinces of the Netherlands there is a large number of evening schools, kept partly for the benefit of pupils of the day schools who wish more extended opportunities for study, and partly for the benefit of young persons employed in stores and factories. The plan of instruction in the higher burgher schools embraces the following studies: natural philosophy, chemistry, natural history, mathematics, the Dutch, French, English, German, and Italian languages, political economy and statistics, bookkeeping, commercial law, knowledge of goods, commercial arithmetic and weights and measures, general history and history of commerce, general and commercial geography, constitution and laws of the Netherlands, history, geography, &c., of India, penmanship, and free-hand drawing. Among the other institutions for secondary instruction are two, one government at Leyden and one municipal at Delft, for the preparation of civil offi-

cers for Dutch India, affording instruction in the Javan and Malay languages, Mohammedan law, the institutions, religions, geography, history, ethnology, and statistics of Dutch India. Holland is rich in educational institutions for the army and navy. Provision is also made for instruction to the inmates of prisons; and there are special schools for the instruction of children between the ages of 4 and 6. Superior instruction is provided for by three universities, Utrecht, Leyden, and Groningen; two atheneums, Amsterdam and Deventer; and 55 gymnasia and Latin schools. The universities have five faculties each: theology, law, medicine, mathematics and natural sciences, and literature. The atheneums have the same faculties and the same course of instruction as the universities; the only difference between them is that the atheneum is not a government but a municipal institution, though under government supervision. The gymnasia and Latin schools afford a classical and mathematical education to students preparing for the universities and professional schools.—The Swiss system of popular education bears a general resemblance to that of the United States. There is, in fact, no national system, but each canton has its own system complete. The administration of educational affairs rests primarily in the cantonal minister of public instruction, aided by a board of three or more members elected from the communes or sections, which are the only school divisions known to the canton. The gradation of the schools and plan of inspection are essentially German. The communal inspectors report to the cantonal, and these to the minister, whatever relates to the fulfilment or evasion of the law and the general condition of the schools. Attendance is obligatory in all but four of the cantons, unless it be shown that children are receiving equally good instruction in private schools or at home; and even then, such children must undergo examinations. In some of the cantons the prescribed school age is from 7 to 14, in others from 6 to 16. The schools are maintained by taxation. Gymnastic and military exercises form a prominent feature, and to provide competent teachers young men are sent by the government to receive instruction in the great gymnastic establishment in Dresden. There are three Swiss universities, situated at Basel, Bern, and Zürich. These are cantonal rather than national, and are organized after the general plan of the German university, but are of inferior rank.—In Italy all matters pertaining to education are under the control of the ministry of public instruction, which has six divisions or bureaus. The first is the financial bureau, through which the payments to all the institutions dependent on the ministry are made; the second has the administration, and gathers the statistics of all the institutions for the fine arts and antiquities, the musical institutions, the libraries, archives, the scientific and literary academies; the third

has the superior instruction, universities, schools for engineers, schools for veterinary surgery, and astronomical observatories; the fourth the institutions for secondary instruction; the fifth the institutions for primary instruction; and the sixth is the auditor's office, through which also all communications to and from the royal court of accounts are transmitted. Elementary education in Italy has been very backward, but the whole system of public instruction is now undergoing a thorough reorganization. The new school law provides for elementary instruction to be given everywhere free of charge, for obligatory attendance upon the schools under penalty of fine, and that no one shall be appointed to any state, provincial, or communal office who cannot read and write.—In China, more than in any other country, with perhaps the exception of Prussia, a learned education is the means of official promotion. Instruction begins in the family, where the boys are taught to enumerate objects, to count to the number of 10,000, and to reverence their parents and ancestors by a minute ceremonial. At the age of 5 or 6 they are sent to school. For the sons of the nobles a higher course of instruction is provided in universities under the surveillance of the state. One of these exists in most of the large cities, and the most advanced of them is the imperial college in Peking. Candidates for admission into this institution are required to pass a strict examination, and the graduates from it are at once appointed to public office. The education of girls is neglected, but the daughters of the wealthy are generally taught to read, write, sing, and sometimes to make verses. For a more complete account of education in this country, see CHINA.—The new school law of Japan, when carried out, will secure a thorough system of education for that country. According to its provisions, the management of educational affairs throughout the country is vested in one central authority, the department of education. For educational purposes the empire will be divided into eight grand divisions, called collegiate, which will be subdivided into 256 academical districts, each to contain a middle or high school, and these again into 53,760 school districts, with one school each. There shall be appointed in every academical district by the local authorities from 10 to 13 directors, each to control from 20 to 30 schools. Every child of all classes must be sent to school from the age of 6 years, and continue long enough at least to finish the elementary course. There are to be three classes of schools: great learning (superior), middle learning (secondary), and small learning (elementary). The different grades of elementary schools embrace common, girls', village, charity, private, infant, and evening schools, and schools for imbeciles. The common (public) schools will have two grades; in the lower will be taught spelling, writing, conversation, vocabularies, reading, morality, letter-writing, grammar, arithmetic, lessons on

health, outlines of geography and of natural history, and gymnastic exercises; in the upper, the outlines of history, geometry, trigonometry, botany, chemistry, and physiology. One or two foreign languages, bookkeeping, drawing, and political economy may also be taught. The lower grade is for children between 6 and 9 years of age, and the upper for those between 10 and 13. The secondary schools, or academies, are intended to afford instruction in the ordinary college branches to those between 14 and 18 years of age. In this grade are also agricultural academies, foreign languages for those preparing for commercial pursuits, and industrial academies. The superior schools will afford instruction in the professional branches, logic, literature, law, and medicine. Normal schools will be established to provide teachers for the public schools. Provision is made for sending about 180 students abroad to receive advanced instruction at the expense of the government. In every class of schools a tuition fee must be paid. The educational funds are under the exclusive control of the department of education.—In the United States the regulation of all matters pertaining to education is left entirely to the states, each of which maintains a system of public instruction independently of the others. These systems differ mainly in details, while the general features are common to all, and give to public instruction in the United States an individuality which distinguishes it from the educational systems of all other countries. In each state instruction is provided by law for all persons of school age, free of all charge for tuition. Attendance is not generally obligatory, but there is a rapidly increasing tendency among educators toward the recognition of the right and duty of the state to educate its entire school population. New Hampshire, Massachusetts, Connecticut, Michigan, and Nevada have laws requiring parents to send their children to school during a specified period between certain ages. The public schools are established and controlled entirely by the people through their chosen officers, and are supported chiefly by voluntary taxation, but partly by funds derived from the sale of government lands and from the gifts of individuals. These schools are entirely independent of any religious organization, and sectarian instruction is carefully avoided; the Bible, however, is generally read in them as a daily exercise. The school system of each state is adopted and all changes therein made by the legislature. The general supervision and control of the educational interests of the state are vested in a board of education or superintendent of public instruction, who are generally elected by the people or appointed by the governor and legislature, and receive a salary. The powers and duties of these officers vary greatly in the different states. The state superintendent generally has his office at the state capital, where he receives reports from the various school districts and local superintendents,

showing how many months of the year each school has continued, how many children have attended, what has been the success of the methods employed, and what is the condition of the schools in every district. This information is embodied in an annual report to the governor or legislature, and distributed among the people. The superintendent has also a sort of judicial supervision of all matters pertaining to schools, is appealed to for the construction of the law, and acts generally for the stimulation and advancement of education. For purposes of local government each state is divided into counties, which are subdivided into towns or townships; a further division of the towns is made into districts of a size suitable for the maintenance of a school. Of these school districts there are 11,350 in the state of New York, and about 167,800 in the United States. In each of them a school is maintained for the accommodation of all the children in the district. In each district officers are chosen by the people who have charge of the school property, employ teachers, provide furniture, fuel, and sometimes books, and have power to levy taxes to meet any expenses that may accrue. In each county there is generally a board of trustees or one or more superintendents or commissioners of public schools chosen by the people to look after their educational interests. Besides these, visitors or inspectors are appointed in each school district or town to inspect the schools and conduct examinations at intervals. By the above mentioned officials all matters pertaining to public instruction are administered, embracing the construction of school houses, the choice of text books and other means for instruction, the examination and appointment of teachers, matters of discipline, the best systems of teaching, and in general whatever may lead to the best results in public instruction. It will be seen that the general supervision of the system is exercised by the state, while the details are determined by the subordinate districts, thus securing local responsibility under state supervision. In the larger cities special provision is usually made vesting the management of the schools in a board of education and a superintendent of public schools. In cities and the larger towns the public schools are graded into primary, grammar, and high schools. The schools are generally open five or six hours a day and about 40 weeks during the year in the cities, but a much less time on the average in rural districts. The school age varies in different states, ranging from 4 to 21 years. After passing through the primary grade, where the ordinary elementary branches are taught, including frequently vocal music, the pupil enters the grammar school, where, in addition to the ordinary branches, music, French, German, drawing, natural philosophy, and chemistry are taught. The time required to pass through these two grades averages about eight years. At this point the education of many pupils ceases, while others

continue through the high schools, where the course of instruction occupies from three to five years, and embraces generally the ancient and modern languages, the higher mathematics, philosophy, &c. In 1872 statistics were collected by the United States bureau of education showing the extent to which music, drawing, French, and German were taught in the public schools of cities containing 10,000 or more inhabitants. Reports were received from 140 cities, from which it appears that the study of vocal music is almost universal in schools of all grades, but only three cities reported instrumental music as among the branches taught in the public schools. Drawing was taught in all the schools of 47 cities, in the high of 4, in the high and grammar of 12, in the grammar of 3, and in the grammar and lower grades of 24; making 90 cities in which drawing was reported as among the studies. German was reported to be taught in 76 cities, viz.: in all the schools of 15, in the high of 33, in the high and grammar of 20, in the grammar of 4, and in the lower grades of 4. Instruction in French was provided by 73 cities; it was a regular study in all the schools of 2, in the high of 63, in the high and grammar of 7, and in the grammar of 1. In some of the cities, and especially in the rural districts, the same schools are attended by both sexes; but in most of the larger cities, especially in the higher grades of schools, separate schools are maintained for boys and for girls. In regard to color, in some instances, no distinction is made in the admissions to the public schools, but more generally colored pupils are required to attend schools specially provided for them. In all the schools pupils pass from a lower to a higher grade after an examination, oral and written, in the studies pursued. These examinations are sometimes conducted by the teacher, but more frequently by other school officers, such as the superintendent of schools or a member of the board of visitors.—In nearly every state there is a normal school for the preparation of teachers; in several, three or four; and in New York, eight. The course of instruction usually occupies two, but sometimes three years, upon the completion of which diplomas or certificates are conferred, which are generally accepted as evidence of qualification to teach in the public schools without further examination. In the absence of such certificates, applicants before being chosen as teachers are required to pass an examination conducted by school officers appointed for that purpose. In many states the system of examining teachers is very deficient. In California a great advance has been made in this respect. State and county boards of examination, composed exclusively of professional teachers, have been organized. The system embraces written examinations and the issue of graded certificates to teach, from life certificates down to limited certificates for temporary teachers. According

to the report of the bureau of education for 1872, there were 101 normal schools in the United States, with 773 instructors and 11,778 students. Of these, 48 schools, with 454 instructors and 7,157 students, were supported or aided by states; 2, with 9 instructors and 182 students, by counties; 7, with 72 instructors and 816 students, by cities; 44, with 248 instructors and 3,623 students, are connected with other educational institutions. In 66 of these schools drawing is taught, and 16 have collections of models, casts, apparatus, and examples for free-hand drawing; vocal music is reported as taught in 74, and instrumental music in 51; 45 possess chemical laboratories, 52 philosophical cabinets and apparatus, and 32 have cabinets of natural history. Model schools are connected with 57 normal schools, and 70 confer diplomas and certificates upon students completing the course. While there has been a steady growth of normal instruction as an element in the educational system of the United States, the present provision is entirely inadequate for the training of the necessary number of teachers, the deficiency being supplied by graduates of other public and private institutions. According to an estimate made by the bureau of education, based on the assumption that teachers do not continue in service on the average more than three years, 120,897 new teachers are annually demanded in the United States, while the normal schools can supply only about 4,000.—Another most important feature of the system of education in the United States is the numerous conventions and associations of teachers and educators held for the discussion of all topics pertaining to education. These organizations are national, state, and county. In many of the states county institutes or teachers' associations are held at frequent intervals during the year, for the purpose of securing a higher degree of efficiency among the teachers by means of lectures and other forms of instruction given by experienced educators, and discussions by teachers themselves. The state organization of teachers usually meets annually, sometimes oftener, under the direction of the state school officers, for the consideration and advancement of the educational interests of the state. The national educational association is composed of the foremost teachers and educators in every department of learning, and meets annually for the discussion of whatever may tend to promote education in any of its branches in the United States. This body, which held its 13th annual session in 1873, comprises four departments: elementary, normal, superintendence, and higher instruction. Besides this, the American institute of instruction meets annually for similar purposes, and there are other national educational associations. In the United States the plan of the school house is recognized as an important element in the system of education, and much attention is given to secure the best models in regard to light, ventilation, location, and other de-

tails affecting the health, comfort, and mental activity of the student. The organization of free evening schools as a part of the system of public instruction is of comparatively recent origin, but the growth in their number and efficiency has been marked. They are provided chiefly in the large cities and manufacturing districts, and are intended to afford instruction in the ordinary branches to those adults and others who are prevented by employment from attending the day schools. Of the 141 cities having 10,000 or more inhabitants that reported to the bureau of education in 1872, 51 had 218 evening schools, with 1,350 teachers and 60,297 pupils; of 82 cities with a population between 5,000 and 10,000, 7 were reported as having 14 schools of this class, with 20 teachers and 555 students; while of 103 cities having less than 5,000 inhabitants, 7 reported 9 evening schools with 312 pupils. —In addition to the public schools, private schools for all grades and classes of students are extensively encouraged and patronized. In this manner many denominational schools are supported, especially by the Roman Catholics. So far as the state is concerned in the control and support of education, public instruction is generally limited to the common schools, embracing the primary, grammar, and high, including academies; and beyond the last named grade means for education in most instances is dependent upon individual or corporate provision. Institutions of the highest class, such as universities, colleges, schools of science, &c., are in a few of the states maintained at the public expense; but in most they are supported by income from tuition and by endowments under the direction of private corporations, which are exempted from taxation. Where tuition is charged, the rate is always low. Institutions of this class are everywhere protected and encouraged by favorable laws and charters. No definite line of classification can be drawn separating universities, colleges, academies, and seminaries for advanced instruction. The mode of organization and government, and the system of instruction, are often the same in an academy as in a college or university. Nor is there any standard of requirements to determine whether an institution shall be admitted to either of these classes. Consequently the variety among colleges, for example, as far as concerns the endowment of the institution, the number of instructors and pupils, the extent and thoroughness of instruction, and the general facilities for affording advanced education, may be so great as to suggest no comparison or similarity. Many institutions, therefore, assuming the name of college or university, are insignificant in comparison with the best institutions of that class. The representative American college is a corporation deriving its charter and powers from the state, and supported by endowment and funds arising from gifts, tuition, &c. Its external adminis-

tration is vested in a board of overseers or trustees, some of whom are appointed by the state, while it is governed more immediately by a faculty composed of professors and instructors. The chief executive officer is a president, generally chosen by the overseers or trustees. The course of study extends through four years, and embraces the ordinary branches of advanced learning, such as ancient and modern languages, mathematics, the sciences, philosophy, logic, &c. Students are admitted at from 16 to 18 years of age, after examination. In most colleges all the studies are required, while in others the student has a choice of different branches. Instruction is administered by recitations and lectures, chiefly the former. Written and oral examinations are frequent, and annual written examinations are held as a condition of passing from a lower to a higher class, there being four classes in all. Degrees are conferred upon those students who pass a successful written examination which is frequently limited, however, to the studies of the last year of the course. Discipline and attention to study are secured by a graded system of marks of merit and demerit. Many of these institutions have various funds for indigent and meritorious students, consisting of prizes, loans, scholarships, &c., arising from gifts by individuals. In some cases a student may defray the expenses of his education from these sources. The degree usually conferred at graduation is that of bachelor (A. B.), while the master's degree (A. M.) is conferred three years later, the only condition except at Harvard being the payment of a fee. The degree of bachelor in the various professional and scientific departments is also conferred, while doctor of divinity (D. D.) and doctor of laws (LL. D.) are granted as honorary degrees. In the United States there is no university or university instruction according to the European classification, especially that adopted in Germany. There are, however, more than 100 organizations that assume that title, which may be divided into three general classes: denominational universities, founded and managed by religious sects; non-sectarian, which, though in the main independent, are partly endowed and controlled by the state; and those originally founded and wholly controlled by the state. Several institutions, however, partake of the university character, such as Harvard and Cornell universities and Yale and Columbia colleges, whose organizations embrace, besides the academic department, professional and technical schools with numerous professorships, libraries, museums, collections, apparatus, &c., for the most advanced instruction. The oldest and most completely developed institution of this class is Harvard university in Cambridge, Mass., which may be taken as a representative of the most advanced instruction afforded in the United States. It embraces an academic department, with a four years' course of study; a divinity school, three

years; a law school, two years; a scientific school, with a four years' course in civil and topographical engineering, three years' courses in practical and theoretical chemistry, in natural history, and in mathematics, physics, and astronomy, besides teachers' courses of one year and instruction for advanced students; a school of mining and practical geology, with a four years' course; medical school, three years; an astronomical observatory, with special instruction; a dental school; a school of agriculture and horticulture; a museum of comparative zoölogy; and the Peabody museum of American archaeology and ethnology. (See HARVARD UNIVERSITY.)—The United States government exercises no control over public education, and makes no regular provision for its support, except that military instruction is afforded at West Point, N. Y., in a four years' course, and also at the school of artillery, Fortress Monroe, Va., and naval instruction at Annapolis, Md., free of charge. These institutions are wholly supported and controlled by the general government, and are intended to provide trained officers for the army and navy. Liberal aid, however, has been extended by congress for purposes of education, by various grants of land dating as far back as 1803. The land granted or reserved for common schools and universities amounts to about 68,000,000 acres, in addition to which 7,830,000 acres were reserved by act of congress passed July 2, 1862, granting to the several states and territories 30,000 acres for each senator and representative in congress, to provide "colleges for the benefit of agriculture and the mechanic arts." The organization and management of these institutions are transferred to the respective states on certain conditions. In almost every state the funds thus realized have been added to those of some existing institution in order that better results may be obtained by the concentration of resources; but in such cases the government funds must be devoted to the special studies for which they were intended. In 1867 an important step, growing out of the numerous inquiries and demands by foreign educators and others for information and statistics concerning education in the United States, was taken by congress in the establishment of a department, now called the bureau of education, "for the purpose of collecting such statistics and facts as shall show the condition and progress of education in the several states and territories, and of diffusing such information respecting the organization and management of school systems and methods of teaching as shall aid the people of the United States in the establishment and maintenance of efficient school systems, and otherwise promote the cause of education throughout the country." At the head of this bureau is a commissioner who makes an annual report to congress, which is printed for gratuitous popular distribution. This report aims to present full information concerning all the educa-

tional institutions in the different states and cities, and all educational forces, such as libraries, museums, newspapers, and periodicals. It also presents a summary of the latest educational information and statistics of all parts of the world, and contains articles on various subjects connected with education. The bureau also publishes in pamphlet form reports on education in different countries. According to this authority, the total school population of the 34 states and 7 territories reporting in 1872 was 12,828,847, and the enrollment 7,379,656. In 28 states and 4 territories reporting, the average attendance was 4,110,525. The number not registered in 34 states and 6 territories reporting was 4,608,803. There were attending private schools in 18 states and 5 territories 364,283. The number of teachers reported in 33 states and 7 territories was 217,239. The total income in all the states and territories from which it is reported was \$72,630,269, of which \$55,889,790 were from taxation; total expenditure for educational purposes, \$70,891,981. In 31 states having a permanent school fund the total amount was reported at \$65,850,572. Of 326 cities in the United States, 295 reported their school population at 2,123,889; in 318, the enrollment was 1,215,897; in 298, the average attendance was 787,860; in 292, the number of schools is reported at 7,917; and in 315, the number of teachers at 23,194. The following summary of educational institutions in the United States is reported by the bureau of education for 1872:

INSTITUTIONS.	No.	Teachers.	Pupils.
Normal schools.....	101	773	11,773
Business colleges.....	66	263	8,451
Academies.....	811	4,501	98,529
Colleges.....	298	3,040	*45,617
Institutions for superior instruction of females.....	175	1,617	11,288
Schools of science endowed by national grant of lands.....	38	411	2,971
Schools of science (including collegiate departments) not so endowed.....	32	313	2,443
Theological schools.....	108	435	3,351
Law schools.....	42	151	1,976
Medical schools, regular.....	61	667	4,887
" eclectic.....	3	25	259
" homœopathic.....	6	72	555
Dental schools.....	59	55	199
Pharmaceutical schools.....	13	36	650
Institutions for the blind.....	27	513	1,566
" deaf mutes.....	36	267	4,387
Reform schools.....	26	331	4,230
Orphan asylums.....	77	852	10,324

From the United States census for 1870 it appears that of the 17,389,784 persons between 5 and 24 years of age inclusive, 7,209,938, or more than one third, were receiving instruction. As the number over 21 under instruction must be very limited, nearly one half of the population between 5 and 20 years of age, inclusive (14,507,658), are reported to be in institutions of learning. The total number of instructors

* Unclassified, 6,694; preparatory, 19,476; collegiate, 19,249.

was 221,042, of whom 93,329 were males and 127,713 females. The total wealth of the country was \$30,068,518,507; the total income of schools, which may also be taken as the total expenditure, was \$95,402,726. Of this amount \$3,663,785 was from endowment, \$61,746,039 from taxation and public funds, and \$29,992,902 from other sources, including tuition. In the United States more than 17 per cent. of the adult males and 23 per cent. of the adult females are illiterate. In a total population of 38,558,371, 4,528,084 persons 10 years of age and over could not read, and 5,658,144, 10 years of age and over were unable to write, including 777,873 of foreign birth and 2,789,689 colored. It will thus be seen that a large portion of the illiteracy is due to those who prior to the civil war were slaves, a fact which is further illustrated by a map published by the census to show the distribution of illiteracy by states. The following statement of illiteracy has been compiled by the bureau of education from the census of 1870:

Aggregate population.....	38,558,371
Total population, 10 years old and over.....	28,238,945
Illiterate population, 10 years old and over.....	5,658,144
Male population, 10 years old and over.....	14,253,566
Illiterate males, 10 years old and over.....	2,603,888
Female population, 10 years old and over.....	13,970,079
Illiterate females, 10 years old and over.....	3,054,256
Percentage of total illiterates to total population of same age.....	20-04
Percentage of male illiterates to male population of same age.....	18-26
Percentage of female illiterates to female population of same age.....	21-87
Total population in 1870, 10-21 years old.....	9,692,945
Illiterate population, 10-21 years old.....	1,942,948
Male population, 10-21 years old.....	4,515,563
Illiterate males, 10-21 years old.....	984,741
Female population, 10-21 years old.....	4,877,080
Illiterate females, 10-21 years old.....	958,207
Percentage of illiterates, 10-21 years old, to population of same age.....	20-05
Percentage of male illiterates to male population, both 10-21 years old.....	20-45
Percentage of female illiterates to female population, both 10-21 years old.....	19-65
Total male adults, 1870.....	9,443,001
Male adult illiterates.....	1,619,147
Total female adults.....	9,092,999
Female adult illiterates.....	2,096,049
Percentage of male illiterate adults to total adults.....	17-15
Percentage of female illiterate adults to total females.....	23-05

—*Professional Education.* The system of professional education in the United States, so far as there is any system, is greatly inferior to that of continental Europe. There instruction in medicine, law, and theology is usually provided by faculties of the university, and is consequently regulated by the government. The conditions of admission and graduation are such as to secure thorough training. In the United States professional schools sometimes form departments of colleges, but are frequently independent of other educational institutions, and usually of the government. The courses of study are shorter and less thorough than in Europe, while the requirements for admission and graduation are far less. The requisites for admission to American medical schools, where any exist, can generally be met by the preparation received in a common school or academy.

The usual course of study is three years, in which are included at least two courses of lectures, when the student receives the degree of M. D. In Italy the applicant for admission to the medical school must have completed the studies of the lyceum—Greek, Latin, and Italian literature, history and geography, philosophy, chemistry, mathematics, natural history, mechanics, and gymnastics. The term of study is six years. In France the standard of admission is even higher; and to obtain the degree of doctor, which alone secures the privilege of full practice in medicine and surgery anywhere in France, the student must have completed a four years' course in one of the great faculties, or the courses in an *école préparatoire* for three and a half years, and at least one annual course in a faculty of medicine; spent two years in a hospital near the faculty or preparatory school; and undergone three annual examinations and five on the completion of his studies, besides preparing a satisfactory thesis. The schools for educating physicians and surgeons for the army and navy are under the direct management of the government. In Austria a certificate of the gymnasium is essential for admission to the medical schools; and a four years' course of study, confined almost exclusively to strictly professional branches, is requisite for admission to the final examinations which all candidates for the doctorate must pass. The course of study in the *medizinisch-chirurgische Facultät* of the royal university in Vienna, the greatest school of medicine in Austria, and in some respects the greatest in Europe, comprises 10 semi-annual courses, in each of which nearly 100 courses of lectures and practical exercises, comprising not less than 9,000 lessons of one hour each in every branch of medicine and nearly every disease within the range of medical practice, are given by 35 full professors, 19 assistant professors, and 39 *Privatdozenten*. The collections, museums, libraries, laboratories, botanical gardens, &c., constitute an array of material aids no less remarkable; while the general hospital, with its numerous divisions for all the important classes of disease, its thousands of beds, and superior facilities for a dozen or more distinct clinics on a large scale, surpasses all others in the world. The Prussian system of medical education is similar to that of Austria. In Great Britain admission to the medical schools is preceded by a thorough examination. The course of instruction is four years, two of which must have been spent in attending the medical and surgical practice of a general hospital having not less than 80 patients.—In the Italian universities a student is required to study law for five years in order to obtain the degree of doctor, and as a condition of admission he must possess the *certificato di licenza* (equivalent to an American A. B.), and pass an oral and written examination in Italian and Latin literature, ancient and modern history, and

moral philosophy. There are 21 faculties of *giurisprudenza*, with an average of 15 full professors, and in some cases honorary and extraordinary professors. There are also special courses in many of the faculties. At the conclusion of the first three years of study the degree of bachelor in law is conferred; at the end of the fourth year, the degree of licentiate; and at the end of the fifth, the diploma of doctor. In France there are 11 faculties of law, with 98 chairs. As in Italy, legal instruction is under control of the state, and the degrees and the general regulations governing admission are the same in both countries. No person in France is admitted to the courses prescribed for any degree unless a graduate in the arts. No one can practise as a barrister (*avocat*) without the degree of licentiate of law, or as a solicitor (*avoué*) without the *certificat de capacité en droit*. To obtain the degree of bachelor, which entitles the holder merely to practise as a solicitor, the candidate must complete the courses of the first two years and undergo examinations in the Institutes of Justinian and the Code Napoléon, the penal code, and the codes of civil procedure and of criminal instruction. The degree of licentiate is conferred only upon those who have received the degree of bachelor, have completed the third year's course of study in a faculty of law, and have passed examinations in the Code Napoléon and the codes of commerce and of administrative law, besides defending a thesis on questions of Roman and French law. To obtain the degree of doctor in law it is necessary to be a licentiate, to complete the four years' course of study, and to pass two examinations on Roman, French, and international law. For those who design to practise in a subordinate capacity, as mere solicitors, notaries public, &c., a *certificat de capacité en droit* is granted at the end of one year's study, embracing the first and second years' courses in the Code Napoléon and the codes of civil and criminal procedure. In the German empire law is taught in the universities, which have 30 faculties of law and about 300 professors. The degree of doctor is the only one conferred; the term of study is four years. The *Maturitätszeugniss* (corresponding to the American A. B.) granted by the gymnasia is requisite for admission. In the Scandinavian states the law schools are not numerous or provided with large corps of instructors. The gradation of studies and the degrees conferred resemble those of the French and Italian, rather than the German schools. Instruction is given by lectures, and examinations are frequent. The Anglo-Saxon schools of law, both in Great Britain and the United States, are regarded as vastly inferior to those of the continent. There are law departments in most of the British universities, which confer degrees only upon those who have a general knowledge of language, literature, and philosophy. In the United States law schools

are generally departments of colleges or universities. The professors number from one to five, and are often judges of the court or practising lawyers. The course of study is usually two years, on the completion of which the degree of bachelor (LL. B.) is conferred almost as a matter of course, the final examination in many cases being merely nominal, or not required at all. Usually no educational or professional requirements for admission exist. In some instances this degree entitles the holder to practise in all the courts of the state; and even without the diploma of any law school, a person may be admitted to the bar upon examination, which is frequently very limited, in certain legal studies.—In Europe the system of ecclesiastical education comprises the two general divisions Protestant and Catholic, while in the United States there are almost as many kinds of theological schools as there are sects. The continental faculties of theology represent the one or the other of those two branches of the Christian church. In Italy, Austria, Bavaria, Belgium, Spain, and Portugal, they are Catholic; in the North German states, in Switzerland, the Netherlands, and Scandinavia, they are Protestant; while in France they are divided. In the United States, where there is no connection between church and state, each denomination guards its own theological interests by the establishment of such schools as may be required. Accordingly the 108 theological schools, with 435 professors and 3,351 students in 1872, were distributed among 19 sects. The multiplication of sectarian theological schools is also a feature of ecclesiastical education in Great Britain, but not so extended as in the United States. This department of education in France is provided for by 7 faculties with 42 professors; Italy, 8 faculties and 64 professors; Prussia, 12 faculties and 112 professors; Austria, 4 faculties and 38 professors; the Netherlands, 3 faculties and 14 professors; Denmark and Norway, each 1 faculty and 5 professors; Sweden, 2 faculties and 8 professors; and Great Britain, 8 faculties and 34 professors. In regard to the subjects taught and the qualifications for admission, there seems to be a nearer accordance among the different nations than in either medicine or law. In Europe the degree of A. B. or the certificate of maturity from the gymnasium is necessary to admission; in the United States the qualifications for admission in some cases are nearly the same, though in most of the theological seminaries little more than a common school education is really required. In France five professorships are regarded as essential (there are sometimes seven), and the term of study is three years; the Italian schools have eight full professors and a course of five years. In Germany the term of study is shorter, being four years in Austria and three in Prussia and most of the other states. The number of full professors is often 10 or 12, besides numerous extraordinary pro-

fessors and *Privatdocenten* who deliver courses of lectures. In Great Britain and the United States the course of study averages three years, and the number of professors is generally about four. The degrees conferred in European countries are those of bachelor, licentiate, and doctor in theology. In Great Britain and the United States only the bachelor's degree (B. D.) is conferred, except that the degree of doctor (D. D. or S. T. D.) is conferred honorarily. Very few of the American seminaries confer any degree in course.—The educational system of Europe embraces special schools devoted to almost every branch of science, art, and industry, viz.: science and art, arts and trades, chemistry, agriculture, forestry, veterinary surgery, mines, engineering, architecture, commerce and navigation, science and art of war, painting, sculpture, drawing, music, &c. In each of these departments special schools are organized with regular courses of study and well defined requisites as to admission and graduation. The extent and variety of schools devoted to special education in Germany are shown by the statement that in 1873 there were in the German empire 140 schools of agriculture, horticulture, &c., 34 of commerce, 27 of navigation, 18 of mining, 17 of forestry, 9 of veterinary surgery, 5 of surgery, 31 of architecture, 17 of music, 6 normal schools of gymnastics, 35 military schools, and 114 technical schools. In the United States many of these schools either do not exist at all, or have a very imperfect organization. In Great Britain and some continental countries schools are maintained for instruction and practical training in some branch of art, trade, or manufacture. The schools of chemistry usually have a two years' course and from six to twelve professors. In the United States there is no distinctive school of this class, but extended courses of instruction in chemistry are given in numerous schools connected with colleges and universities. Schools specially designed to give instruction in the applications of science to agriculture were founded in Prussia, Switzerland, and Austria as early as 1799, and they have since become general throughout Europe. The royal agricultural school of Hungary at Altenburg has nine professors and a two years' course. The applicant for admission must have completed the course of study embraced in the first seven classes of a gymnasium or the first five of a realschule.—The Russian agricultural schools rank among the best in Europe. The Petrovskoi agricultural and forestry academy near Moscow, established in 1865, has a faculty of agriculture and one of forestry, with 18 professors, and a farm of 1,200 acres. The course of study occupies three years in each faculty, and embraces the following general departments: agriculture, zoötechny, veterinary science and art, rural constructions, civil engineering, sylviculture, agriculture and forest technology, and rural and political economy. The academy con-

fers the degrees of bachelor and master, which are obtained only on examination. As early as 1837 the importance of creating state colleges of agriculture in the United States was urged by prominent agriculturists; but no institution of this kind was established till 1857, when the state agricultural college of Michigan was opened with seven professors and a farm of 676 acres. Similar institutions were soon organized by other states, and in 1862 congress passed an act providing for the establishment of colleges of agriculture and the mechanic arts in all of the states and territories, endowing them with about 8,000,000 acres of the public lands. Nearly all of the states have taken steps to organize institutions pursuant to this act, and in several of the states the institutions are in successful operation.—Numerous schools of mines of a high order are maintained in France, Saxony, Prussia, Austria, Sweden, Russia, and other European countries. The course of instruction is from three to four years, although in the imperial school of mines in St. Petersburg, which has 36 professors, it extends through eight years. In the United States schools of mining are of recent origin, and are connected with other institutions, as for example that connected with the Massachusetts institute of technology, the Lawrence scientific school of Harvard university, the Sheffield scientific school of Yale college, the mining school of Columbia college in New York, &c. The term of study varies from two to three and four years, on the completion of which the degree of mining engineer is conferred.—Schools of commerce of a high grade are maintained in most European countries, both separate and in connection with other institutions. Owing to the high character of this branch of education in France, commerce might be almost regarded as a profession. In the United States commercial training is afforded only by the business colleges established and maintained by private enterprise.—Perhaps the most extensive and magnificent institutions in Europe devoted to special education are the polytechnic schools, which are found in most of the continental countries. In the front rank of this class is the polytechnic school at Carlsruhe, Baden, which has upward of 50 instructors and more than 500 students. The main object of the institution is to educate engineers, machinists, architects, chemists, foresters, and agriculturists. It is divided into: 1, the mathematical school, with a course of two years; 2, the school for engineers, course two years and a half; 3, the school for machine builders, course three years; 4, the school of architecture, course four years; 5, the school of chemistry; 6, the school of forestry, with three different courses; 7, the school of agriculture, with a course of two and a half years. The standard of admission is very high, and the instruction is thorough. The system of polytechnic schools has been less developed in Great Britain than on

the continent, but ample instruction of this kind is afforded in the former country by numerous schools of the arts and academies of design, mechanics' institutes and museums with courses of lectures on various branches of applied science, and universities for the working classes, such as the Andersonian university in Glasgow, in which working men and others have the advantage of regular courses of lectures on the sciences. In the United States, the chief polytechnic schools, at least those distinctively so called, are the Massachusetts school of technology in Boston, the Rensselaer polytechnic institute in Troy, N. Y., the polytechnic college of Pennsylvania, in Philadelphia, and the Stevens institute of technology, in Hoboken, N. J. The first named institution, founded in 1862, comprises: 1, a school of industrial science; 2, a museum of arts; 3, a society of arts. The course of study is four years. Candidates for admission must have attained the age of 16 years and pass an examination in the branches ordinarily taught in a high school or academy. The objects of the institute are: 1, to provide a full course of scientific studies and practical exercises for students seeking to qualify themselves for the professions of the mechanical engineer, civil engineer, practical chemist, engineer of mines, and builder and architect; 2, to furnish a general education founded upon the mathematical, physical, and natural sciences, English and other modern languages, and mental and political science; 3, to provide courses of evening instruction in the main branches of knowledge above referred to for persons of either sex. Instruction of this kind is provided for in other institutions, and will constitute a feature in the colleges of agriculture and the mechanic arts endowed by the national grant.—Prominent among the excellent special schools of various kinds maintained in Europe, which are either not found in the United States or exist only in a very imperfect state, are the schools of forestry, which have contributed largely toward the preservation and better cultivation of forests. Among the best are those of Austria, which possesses vast public and private forests. The aim of these schools is to give a thorough theoretical and practical instruction in woodcraft, so as to prepare competent foresters and hunters. Instruction is classified into lower, middle, and superior; the course is from one to three years. The imperial academy of forestry at Mariabrunn is under the immediate administration of the minister of agriculture; it has one director and four professors, and a course of three years.—Until recently there have been in the United States either no opportunities for public instruction in veterinary science, or they have been exceedingly limited. The Massachusetts agricultural college and Cornell university have each a professor of veterinary science; and since 1857 there has been a veterinary college in New York which claims to

be the only regular institution of this kind in the country. The United States commissioner of education, John Eaton, estimating the value of all the horses in the United States at \$800,000,000, concludes "that the proportion of this amount annually lost for want of skilful medical treatment is not less than \$15,000,000." In Europe there are more than 25 well organized veterinary colleges, the best of which are found in Germany. The aim of the imperial school of veterinary surgery in Vienna, which may be taken as an example, is to educate veterinary surgeons for the army and the civil service, to advance the science of veterinary surgery, and to treat sick animals of every kind in its large and well appointed hospital. Instruction is theoretical and practical, the course lasting three years for students and two years for doctors of medicine and surgery who have taken a university degree. Besides annual examinations a rigorous examination is held at the end of the course, when certificates are given which entitle the graduate to become a veterinary surgeon in the army or in the civil service. A special two years' course of horse-shoeing, for private cavalry and artillery soldiers, is connected with the schools. When this is successfully completed, a certificate of "privileged horseshoer" is given. In some other veterinary schools the course of instruction is four years.—Schools of navigation are found in most of the maritime countries of Europe, the object of which is to train mariners and masters of merchant vessels. The school of navigation at Stettin, Prussia, has a director, two professors, and an assistant who teaches drawing. Lessons are given 32 hours a week for three years, the first being a course for pilots, while during the last two the art of navigating the high seas is taught.—Schools for nurses (midwives) are common in Europe, and in some countries no woman is allowed to practise as midwife unless she is provided with their certificate. Austria has eight of these schools, and instruction of the same kind is also given to women at the faculties of medicine in the universities and at the schools of surgery. The course of instruction occupies four, five, or six months. It is both theoretical and practical, and is given by a professor of obstetrics, aided by a midwife and a nurse. A thorough examination is held at the end of the course. In the Austrian schools for midwives more than 1,200 are instructed every year. The United States are very deficient in means for such education, though a few of the medical colleges have courses of lectures for nurses, and the number of female medical schools is increasing.—Special schools of architecture, although of comparatively recent origin, now form a part of the educational system of various continental countries. In the royal architectural academy of Berlin instruction is given by more than 20 professors besides numerous assistants, and extends through from five to seven years. A certificate of builder is given after a two years'

selected course and one year of practice; and that of architect after three years' study and two of practice.—Among the most valuable works on the subject of education are: Schwarz, *Erziehungslehre* (Leipsic, 1829); Cramer, *Geschichte der Erziehung und des Unterrichts in welthistorischer Entwicklung* (Leipsic, 1832-'8); Cousin, "Report on Public Instruction in Prussia" (New York, 1835); Foster, "Educational Reform" (London, 1837); Bache, "Report on Education in Europe" (Philadelphia, 1839); Von Raumer, *Geschichte der Pädagogik seit dem Wiederaufblühen classischer Studien* (Stuttgart, 1843-'52); Fritz, *Esquisse d'un système complet d'instruction et d'éducation* (Strasburg, 1841-'3); E. D. Mansfield, "American Education" (New York, 1851); Henry Barnard, "National Education in Europe" (New York, 1854); Edison, "National Education" (London, 1855); Horace Mann, "Lectures on Education" (Boston, 1855); Théry, *Histoire d'éducation en France* (Paris, 1858); Wiese, *Das höhere Schulwesen in Preussen* (Berlin, 1864); Lowe, "Primary and Classical Education" (Edinburgh, 1867); Blake, "American Schools and Colleges" (London, 1867); Matthew Arnold, "Schools and Universities on the Continent" (London, 1868); Randall, "First Principles of Popular Education and Public Instruction" (New York, 1868); Staunton, "The Great Schools of England" (London, 1869); Arnott, "National Education" (London, 1869); Roberts, "National Education" (London, 1869); "Report on Education," by John W. Hoyt, United States commissioner on education to the Paris exposition of 1867 (Washington, 1870); J. W. Hoyt, "University Progress" (New York, 1870); *Encyclopädie des Erziehungs- und Unterrichtswesens*, edited by Dr. K. A. Schmid of Stuttgart (81st part, 1871); Barnard, "National Education," German States (New York, 1871); Randall, "History of the Common School System of the State of New York" (New York, 1871); Hazen, "The School and the Army in Germany and France" (New York, 1872); "Report of Committee of Council on Education for 1871-'2," Great Britain (London, 1872); Carl Rosenkranz, *Die Pädagogik als System* (Berlin, 1847; English translation by Anna C. Brackett, St. Louis, 1873); Dr. G. A. Riecke, *Erziehungslehre* (3d ed., Stuttgart, 1873); Herbert Spencer, "Education, Intellectual, Moral, and Physical" (New York, 1873); "Education in Japan, a Series of Letters addressed by prominent Americans to Arinori Mori" (New York, 1873); Northrop, "Education Abroad" (New York, 1873); Rigg, "National Education in its Social Conditions and Aspects, and Public Elementary School Education, English and Foreign" (London, 1873). See also Lüben's *Pädagogischer Jahresbericht*, published annually at Leipsic; Wolfram's *Allgemeine Chronik des Volksschulwesens*, published annually at Hamburg; annual reports of the United States bureau of education, beginning with 1870, also numer-

ous circulars of information published by that bureau; and the annual reports of the superintendents and boards of education for the various states and cities of the United States.

EDWARD I., surnamed the Elder, king of the West Saxons, son and successor, in 901, of Alfred the Great, died in 925. His claim to the throne, though recognized by the witenagemote, was disputed by his cousin Ethelwald, who gained the support of the Northumbrian and East Anglian Danes. The rebels marched through the counties of Gloucester, Oxford, and Wilts, and Edward, unable directly to oppose them, retaliated their ravages in the country of the East Angles. He thought proper to withdraw his army, loaded with booty, before the approach of the rebels; but the Kentish men, greedy of more spoil, stayed behind in defiance of orders. They were assaulted by the East Angles, and resisted so valiantly that, though at last obliged to retreat, it was not till after they had slain a great number of the enemy, and had terminated the rebellion by causing the death of Ethelwald himself. The reign of Edward was occupied with subduing the turbulent Danes, who abounded and were constantly reinforced in the provinces of East Anglia and Northumbria. In this he was assisted by his sister Ethelfleda, who governed Mercia. He protected his territories by fortresses which gradually became centres of trade and population. He gained two victories at Tomsford and Maldon, and subjected all the tribes from Northumbria to the channel. His sons Athelstan, Edmund, and Edred successively occupied the throne.

EDWARD II., surnamed the Martyr, king of the Anglo-Saxons, son and successor of Edgar, born about 962, ascended the throne in 975, and was murdered in 978. His stepmother Elfrida raised a faction in favor of her own son Ethelred, who was but seven years of age. Ecclesiastical parties took opposite sides, the married clergy who had been ejected in the preceding reign regarding Elfrida as their patroness and supporting the pretensions of Ethelred, and the monastic followers of St. Dunstan maintaining the claim of Edward. A civil war had already begun, when at a general meeting of the witenagemote Edward, after much opposition, was formally accepted as king. The strife among the clergy still divided the kingdom, and the party opposed to St. Dunstan plotted the murder of the young monarch. He was stabbed in the back at Corfe castle, the residence of his stepmother, as he was drinking a cup of mead on horseback, and sinking from his seat was dragged away by his horse. Ethelred II. succeeded him.

EDWARD III., surnamed the Confessor, king of the Anglo-Saxons, son of Ethelred II. and successor to Hardekanute, born at Islip, Oxfordshire, about 1004, ascended the throne in 1042, and died Jan. 5, 1066. His mother was a Norman princess, Emma, and during the Danish

domination which succeeded the death of Edmund Ironside he dwelt in exile in Normandy. On the death of Canute in 1035 he crossed the channel with 40 ships, and landed at Southampton. He found himself opposed by his mother, who had become a second time queen of England by marriage with the Danish monarch, and was now regent of the kingdom. Menaced by a constantly increasing force, he hastily retreated. With his brother Alfred he received a perfidious invitation from King Harold to cross the sea in 1037. Alfred was murdered at Guildford, but Edward escaped into Flanders. After the accession of his half brother Hardicanute, Edward was received with honor into England, and was at court when the king suddenly died in 1042. The Danish heir Sweyn was then absent from the kingdom; the rightful heirs of the Saxon line, the sons of Edmund Ironside, were in exile in Hungary; the Anglo-Saxons were determined to throw off the Danish yoke; the Danes were divided and dispirited; Edward was the nearest to the throne of any one present, and after a short period of hesitation and commotion he was recognized as king in a general council at Gillingham. During his reign the mutual aversion of the two fierce Teutonic peoples, whose struggles had vexed the country during six generations, began to subside, intermarriages and a blending of language and customs having nearly effaced the distinction between them, and the Normans began to exercise a potent influence in the country. The first royal act of Edward was to dispossess his mother of her immense treasures, and to confine her for life in a monastery at Winchester. The government was in the hands of three powerful noblemen: Earl Godwin, who ruled all the southern provinces; Earl Leofric, who governed Leicester and the northern counties of Mercia; and Earl Siward, whose sway extended from the Humber to the confines of Scotland. Edward married Earl Godwin's daughter Editha, a lady praised by the chroniclers for her learning, piety, and benevolence; but his motive was merely political, and the alliance proved a source of enmity between the king and his father-in-law. Edward was partial both to Norman manners and people; many foreign churchmen and dignitaries had followed him to England, where they had acquired influence in the government. A popular jealousy was already felt against them, when in 1051 Eustace, count of Boulogne, with his train, visiting England, quarrelled with the burghers of Dover, and in the tumult several persons were slain. Edward gave orders to Godwin, in whose government Dover lay, to chastise the insolence of the men of that city. The earl refused to obey; and three armies under the command of Godwin and his two sons immediately marched against the king in Gloucestershire. Edward summoned to his aid Leofric and Siward, and was quickly in a condition to intimidate his opponents, when it was agreed to refer the dispute

to the witenagemote. But Godwin fled with his wife and sons to Flanders; their estates were then confiscated, and Queen Editha was confined in a monastery. Tranquillity was hardly restored when William, duke of Normandy, the future conqueror, reached the coast of England to assist his royal kinsman. He was received honorably, visited several of the royal villas, and was dismissed with magnificent presents. Godwin, having gradually collected a fleet, suddenly appeared in 1052 on the southern coast of England, swept away the ships from the harbors, entered the Thames, menaced London, and extorted from the king the restoration of himself and his son Harold to their earldoms and the banishment of the foreigners. Godwin did not long survive this triumph, and left his possessions to his son Harold. At this period occurred the events which form the groundwork of Shakespeare's tragedy of "Macbeth." In 1039 Macbeth, a turbulent nobleman, murdered Duncan, king of Scotland, chased Malcolm, his son and heir, into England, and usurped the crown. The exiled prince received from Edward permission to vindicate his rights with an English army, and at length in 1054 was successfully supported by Macduff, thane of Fife, and Siward, earl of Northumberland. But the support which Edward gave to Malcolm resulted in adding largely to the power of his own most ambitious and dangerous subject. To oppose Harold's progress, the king invested Algar, the son of Leofric, with the government of East Anglia, which, after a struggle, he succeeded in holding. At Algar's death in 1058 Harold was left without a rival, the most powerful subject in England. Edward the Outlaw, the Saxon heir to the throne, after a life of exile, died within a few days of his arrival in England, and there now stood between Harold and the crown only the returned exile's young and feeble son Edgar. The infirm old king turned his eyes toward his kinsman, William of Normandy, as a person whose capacity and power would render him the most formidable rival to Harold; but he was deterred by the latter, on his return from Normandy, as Hume says, from abdicating in William's favor, and Harold was crowned on the day of Edward's death. The laws and customs of "good King Edward" were long remembered with popular affection. He was highly esteemed for his sanctity, was the first English prince that touched for the king's evil, and was canonized and styled "the Confessor" about a century after his decease. The most commendable feature of his government was his attention to the administration of justice, and to collecting the laws of the realm.

EDWARD I. (of the Norman line), king of England, surnamed Longshanks, from the excessive length of his legs, son of Henry III. and of Eleanor of Provence, born in Westminster, June 16, 1239, crowned Aug. 19, 1274, died July 7, 1307. Being invested with the duchy

of Guienne, his right to that province was disputed by Alfonso X. of Castile, who renounced his claim in consequence of Edward's marrying his sister. In 1254 he received the lordship of Ireland and of the provinces which had been seized in the reign of John Lackland by the king of France. He supported the throne against the revolted barons, and with his father and his uncle Richard, king of the Romans, was made prisoner at the battle of Lewes, May 13, 1264. He recovered his liberty in 1265, defeated and slew Simon de Montfort, earl of Leicester, at Evesham, and in 1267 conquered the last of the insurgents in the isle of Ely. Shortly after he joined the crusaders, and served two years in the East. Nearly two years after his father's death he was crowned without opposition at Westminster, and began to signalize his ability both as a warrior and legislator. His arms were first directed against Llewellyn, prince of the Welsh, whom he reduced, but who rebelled again, and was slain in single combat by an English knight immediately after the army of Edward had reappeared in that country. He established corporate bodies of merchants in the principal towns of Wales, and introduced the jurisprudence of the English courts. Edward, as the chroniclers have it, had promised to appoint as prince of Wales a person born in the principality, and who could not speak English. His queen, Eleanor, being delivered of a son in the castle of Carnarvon, the English king maintained that his son fulfilled the conditions, and declared him prince of Wales, a title which has ever since been borne by the eldest son of the sovereign. In 1289 he resolved upon the subjugation of Scotland, to whose crown there were at this time 13 claimants. Being invited to the office of arbitrator, he took possession of many of the Scotch fortresses, and then conferred the crown upon John Balliol, who soon renounced his allegiance. Edward marched again across the Tweed, gained a great victory at Dunbar in 1296, sent Balliol into exile, bore away the Scotch sceptre and crown, and left the highest offices in the hands of Englishmen, under the earl of Surrey, who received the title of guardian of the kingdom. The Scots rallied in 1297 under the chieftain William Wallace, and drove the English out of their kingdom, totally defeating them in the battle of Stirling, Sept. 10. Edward hastily finished the war which he had meanwhile undertaken in France, advanced again to the Forth, and defeated the insurgents with the loss of from 20,000 to 40,000 men near the forest of Falkirk, July 22, 1298. Wallace himself escaped. The rebellion again broke out in 1303, and again Edward overran the kingdom, its temporary subjugation being completed by the surrender of the strong castle of Stirling. Wallace was soon after surprised and captured, and was hanged in Smithfield (1305). In 1306 the war was again kindled by Robert Bruce, who was elected king, and,

though at first unsuccessful, at length gained a decisive victory over the earl of Pembroke. Edward marched again to the north, but was surprised by death on the frontier at Burgh-upon-Sands. The most enduring results of the reign of Edward were the reforms which he introduced in the administration of government, of justice, and of the finances, which had gained for him the title of the "English Justinian." He ameliorated the laws, confirmed and finally established the two great charters, gave to the parliament the form it has since retained, and is said to have first instituted justices of the peace. The Jews during his reign were cruelly despoiled, and in 1290 ordered under penalty of death to quit England for ever before a certain day.—See "History of the Life and Times of Edward I.," by William Longman (2 vols., London, 1869).

EDWARD II., king of England, son and successor of the preceding, born in Carnarvon, April 25, 1284, ascended the throne in 1307, and was murdered Sept. 21, 1327. From his childhood he had lived in close intimacy with Piers de Gaveston, the son of a gentleman of Guienne, who was at length banished from the kingdom as a corrupter of the prince. Edward I. on his deathbed forbade his son under pain of his paternal malediction to allow the vicious favorite to return; yet the first act of the new king was to recall Gaveston, whom he created earl of Cornwall and married to his own niece, and to the scandal of the whole kingdom appointed him regent while himself went to France to marry the princess Isabella. A formidable league under the earl of Lancaster drove Gaveston into exile; but he was appointed lieutenant of Ireland by his royal friend. He returned soon after, when an army raised by confederate powerful barons and commanded by the earl of Lancaster pursued him to the north; he was besieged at Scarborough, captured, and put to death at Warwick, June 19, 1312. Edward then turned his attention to the revolted Scots. At the head of an immense army he crossed the frontier, but after losing the battle of Bannockburn (1314) fled from the kingdom with a body of Scottish cavalry at his heels. In 1321 he was again defeated at Blackmoor, and pursued to the walls of York. The public discontent was increased by the honors which the king bestowed upon Hugh le Despenser, a new favorite, and an armed insurrection of the barons under the earls of Lancaster and Hereford caused the Despensers to be banished; but on their return Lancaster was seized and put to death. In 1323 Edward negotiated a truce for 13 years with Scotland. The triumph of the Despensers was complete, but the partiality of the king for his favorites alienated not only his subjects but his queen. To arrange some differences between her husband and her brother she went to France, where she found a great number of English fugitives, the friends of Lancaster,

the most considerable and potent of whom was the young Roger Mortimer. A domestic rebellion supported by a foreign invasion was projected, and in September, 1326, the queen with a foreign force of 3,000 men, led by Mortimer and John of Hainaut, landed on the coast of Suffolk. The most powerful nobles and prelates hastened to meet her, and Edward, having in vain appealed to the citizens for support, retreated to the marches of Wales. The queen pursued him, and he was captured at Neath abbey, Glamorganshire, and sent to the castle of Kenilworth. The favorite Despen-ser was taken at the same time and hanged. The parliament being assembled, by the influence of Isabella and Mortimer, it was resolved, in January, 1327, that the reign of Edward of Carnarvon had ceased. While imprisoned in Berkeley castle under the charge of ruffians employed by Mortimer, Edward II. was found dead in his bed in the morning after shrieks had been heard from his apartment, and his distorted features betrayed the agony in which he had expired. It is said that his bowels were burned out with a hot iron.

EDWARD III., eldest son of Edward II. and Isabella of France, born at Windsor, Nov. 13, 1312, proclaimed king of England Jan. 23, 1327, died at Shene (now Richmond), June 21, 1377. At the age of 12 he went with a splendid retinue to France to do homage to Charles IV. for the possession of Guienne and Ponthieu, which had been resigned to him by his father. He remained with his mother at the French court, was contracted in marriage by her to Philippa, daughter of the count of Hainaut, whom he married Jan. 24, 1328, and was declared king after the captivity of his father. A council of regency, consisting of four bishops and ten noblemen, most of whom, being of Isabella's party, gave up to her and Mortimer (now created earl of March) the ascendancy in the government, had but just been appointed, when Robert Bruce, in violation of the truce, sent an army of 24,000 men under Randolph and Douglas, which ravaged the county of Cumberland. Young Edward marched to the north with more than 40,000 men, made a vain pursuit of the Scots, came up with them twice when they were in inaccessible positions, is recorded to have wept when he found himself outgeneralled by an inferior enemy, and concluded an inglorious campaign by a treaty in which the entire independence of Scotland was recognized. The odium of this settlement was thrown upon Isabella and Mortimer, who increased their unpopularity by intrigues against the earl of Kent, whom they caused to be executed for high treason in 1330. In the same year Edward asserted his own authority against his mother and her paramour. Mortimer was executed for high treason at Smithfield, and Isabella was confined for the rest of her life in the manor of Risings. He immediately renewed his father's project of conquering Scot-

land, and secretly encouraged the claim of Edward Balliol to the crown of that country, who was willing to hold it as a fief of the English monarch. Balliol won the crown and lost it within three months, and the incursions of the Scots gave to Edward a pretext for renewing the war. He laid siege to Berwick, and on July 19, 1333, defeated on Halidon hill with great loss the army of the regent Douglas. The town and castle were immediately surrendered, and Balliol, being again seated on the throne of Scotland, ceded a large territory to England, a measure which was followed by his flight to that country within four months. Three times in three years Edward invaded and devastated Scotland in support of Balliol, and then laid claim to the crown of France against Philip of Valois. The ground of this pretension was, that although females were excluded from the French throne, their male descendants were not; and that as the son of Isabella, the daughter of Charles IV., his claim was better than that of Philip, who was descended from a younger brother of Charles IV. Edward made alliance with several continental princes and rulers, the chief of whom were Louis the Bavarian, emperor of Germany, the dukes of Brabant and Gueldres, and James van Artevelde of Ghent. He formally published his claim in 1337, and in the following year sailed with a numerous fleet to Antwerp, designing to begin the campaign with the siege of Cambrai; but perceiving the difficulty of the enterprise, he advanced into France with about 50,000 men, was almost confronted with an army of nearly double that force under Philip, yet no engagement ensued, and he returned to Brussels and disbanded his army without having derived any advantage from his immense expenditures. He returned to England in 1340, obtained an unprecedented grant from parliament, defeated a French fleet off Sluis, returned to the continent, and at the head of nearly 200,000 men, including his Flemish allies, undertook at the same time the sieges of Tournay and St. Omer, both of which were unsuccessful; and he quickly concluded an armistice for nine months, and soon after another for three years and eight months. Another English campaign in France was begun in 1346 under the earl of Derby, and prosecuted with uninterrupted success. Edward also landed with a numerous force on the coast of Normandy, advanced to Rouen, sent his light troops to insult the faubourgs of Paris, and on Aug. 26 gained over Philip the decisive battle of Crécy. The siege of Calais followed, and while the chivalry of England lay before the walls of that city, the Scots suddenly crossed the frontier, but were defeated near Durham by a miscellaneous and rapidly collected army, and their king David captured. Calais surrendered after an obstinate defence, and a truce followed which lasted till 1355. Meantime Edward invaded and widely desolated Scotland, causing a havoc long remem-

bered. The war was renewed in France under the Black Prince, who gained on Sept. 19, 1356, the memorable victory of Poitiers, in which he took King John of France prisoner. The Scottish king was ransomed for £100,000 in 1357, and in 1360 the "great peace" was concluded at Bretigny, by which Edward renounced his pretensions to the crown of France and restored his conquests, retaining only the full sovereignty of Poitou, Guienne, and the county of Ponthieu. Though the misfortunes of the latter years of his reign contrasted strongly with the glories of its commencement, and though his victories left few lasting acquisitions, yet they gave to England a lustre and renown which were long her strength and safety. In his reign the elegant arts began to be cultivated, the castle of Windsor was rebuilt, and English poetry and prose may be said to have been begun. He was succeeded by his grandson Richard II.

EDWARD IV., king of England, born in Rouen, April 29, 1441, died April 9, 1483. The lot of the feeble Henry VI. fell in an age of violence, to which he brought only meekness of spirit. His own insignificance, the dishonor of the English arms, and the passionate tyranny of his indomitable queen, Margaret of Anjou, revived the long forgotten pretensions of the house of York. The great Lancastrian chiefs, Cardinal Beaufort and the dukes of Bedford and Gloucester, who supported the throne during the minority of Henry, were dead, when Richard, duke of York, the father of Edward IV., cautiously and gradually advanced his claim to the throne, gained the support of the powerful earls of Warwick and Salisbury, took arms against Somerset, the last great nobleman of the Lancastrian branch, and began by a victory at St. Albans, in 1455, the wars between the red rose of Lancaster and the white rose of York. The claims of both these Plantagenet lines were derived from Edward III. From the first two sons of that sovereign no issue survived; the three Lancastrian kings who had occupied the throne for more than half a century were descended from the fourth son; the dukes of York were descended from the fifth son, but had also by intermarriage become heirs to the rights of the third son. The question was rendered more complicated by the irregular accession of the first Lancaster while Edmund Mortimer, heir of the third son, was alive, and by decrees of parliament. Richard, duke of York, after various successes and reverses in maintaining his claim, was defeated and slain by Queen Margaret, at Wakefield, in 1460; but young Edward immediately put himself at the head of an army of Welsh borderers and mountaineers, and defeated a formidable force under the earls of Pembroke and Ormond, near Hereford. He then marched southward, supported by the earl of Warwick, who suffered a defeat near St. Albans by which Henry was again restored to his friends. Edward marched di-

rectly to London, which he entered without opposition, and where his youth, boldness, and beauty gained him the public favor. He was proclaimed king by parliament, March 4, 1461, and thus there were two kings and two royal armies in the land. Both parties made formidable preparations for battle, and at Towton, near York, 100,000 Englishmen were drawn up, in not very unequal division, in hostile array. Proclamation had been made that no quarter should be given, and the battle (March 29, 1461) was probably the bloodiest ever fought in England. It lasted more than a day, and ended, after the slaughter of over 30,000 persons, in the total rout of the Lancastrians; and thus the crown was firmly placed on the brow of Edward IV. Margaret sailed to France, seeking the alliance of the French king; and in 1464 she appeared again in Scotland, at the head of only 500 French troops, with whom, and a band of Scottish borderers, she gave battle to the English general, Lord Montacute, near Hexham. The Lancastrians were again completely routed; the king and many of the chiefs were captured, and Margaret again made her escape into France. Edward, anticipating the maxim of Machiavelli, made a terrible slaughter of his enemies in the first moment of victory, and in his subsequent administration ruled with clemency. After this second retreat of Margaret, he devoted himself for a time to pleasure. He had privately married Elizabeth, widow of Sir John Gray and daughter of Richard Woodville, Baron Rivers, whom he had met at her father's house while hunting in the forest of Grafton. In September she was publicly acknowledged queen, and her father was made an earl. This union displeased the powerful and haughty earl of Warwick, who had been authorized to negotiate a marriage between the king and the princess Bonne of Savoy, and had succeeded in doing so. Allying himself with Edward's brother, the duke of Clarence, he revolted in 1469. The effect of his combination with the discontented nobility and gentry was quickly seen in seditions fomented in every part of the country. In Yorkshire, Robin of Redesdale, a hero among the troopers of the frontier, took the field with 60,000 men. Edward marched against them. Warwick, absent in France, had gained the favor of Louis XI., and become reconciled with his old enemy Margaret. He landed at Dartmouth with a small body of troops, where his popularity swelled his army in a few days to more than 60,000 men. He advanced to the north, and his approach shook the fidelity of the royal troops. Edward fled in 1470 to Holland, and his imprisoned rival was led forth from the tower to hear the streets of London resounding once more with the name of King Henry. A parliament was summoned in the name of the restored king, by which Edward was pronounced a usurper, his adherents were attainted, and all acts passed by his authority repealed. Secretly assisted by the duke of

Burgundy, Edward collected a body of Flemings and Dutchmen in a few months, with whom he landed at Ravenspur. He advanced into the interior, pretending at first that he came only to recover his patrimony as duke of York, and making his followers cry "Long live King Henry," till he received reinforcements which put him in a condition to face the enemy. The armies met at Barnet on April 14, 1471, and the Lancastrians were defeated and Warwick himself was slain. Edward again became master of London, and of the person of Henry, who was remanded to the tower. Meanwhile Margaret, with her son Edward, 18 years of age, landed at Weymouth at the head of a body of French troops on the very day of the battle of Barnet. With an army commanded by the duke of Somerset she made a stand at Tewkesbury, May 4, 1471. Her army was defeated, her son Prince Edward slain, and she herself taken prisoner and held in captivity five years, when she was ransomed by the king of France. Her husband perished in the tower a few weeks after the battle. Edward formed an alliance in 1474 with the duke of Burgundy, by which France was to be divided into two states, one of which, comprehending the northern and eastern provinces, should belong to Burgundy, and the other should be possessed by England. He passed over to Calais with a force of archers and men-at-arms, only to be disappointed by the duke of Burgundy, who sent his apology instead of an army, and to make an advantageous treaty with Louis without a battle. By this treaty pensions of considerable amounts were bestowed by Louis not only upon the English king, but upon all the considerable persons of the English court. Edward then became involved in a bitter strife with his brother Clarence. The interference of Edward prevented the marriage of Clarence with the wealthy heiress of Burgundy; soon afterward two of the friends of Clarence were put to death upon a frivolous pretence, joined with an accusation of sorcery; and when he maintained their innocence, he was himself privately put to death in February, 1478, on a charge of treason for arraigning public justice. During the latter part of his life Edward was sunk in indolence and pleasure. He left five daughters, of whom Elizabeth was afterward married to Henry VII.; and two sons, the ill-fated princes Edward and Richard.

EDWARD V., king of England, of the York branch of the Plantagenets, son and successor of the preceding, born Nov. 4, 1470, in the sanctuary of Westminster abbey, whither his mother had fled from the army of the Lancastrian Queen Margaret and of Warwick, died doubtless by murder in the tower of London in 1483. At the time of his father's death, April 9, 1483, young Edward was residing on the borders of Wales, in the care of Earl Rivers, brother of the queen. In company with Rivers he immediately set out for London, while the duke of Gloucester, brother

of the late king, and now regent during the minority, started south from York, attended by a splendid retinue. The two processions met at Stony Stratford, when Gloucester approached the young prince with the greatest demonstrations of respect, but soon after charged Rivers and the queen's son, Sir Richard Grey, with having aimed to estrange from him the affection of his nephew, arrested and imprisoned them in the castle of Pomfret, and endeavored unsuccessfully to satisfy Edward with regard to the violence thus exercised upon his kindred. The king was from this time a captive. The queen mother hastily took refuge with her second son, the duke of York, and her five daughters, in the sanctuary at Westminster. Gloucester postponed the coronation of the young king, confined him for security in the tower, and was formally invested with the office of protector. His next step was to withdraw the duke of York from his retreat with his mother at Westminster; but he had still to fear opposition on the part of those noblemen, such as Lords Hastings and Stanley, who were friends of the late king, and unswerving in their fidelity to his children. Their destruction or imprisonment without form of trial, or even specification of offence, swiftly followed. Earl Rivers also and his friends were put to death without any semblance of judicial forms. The amours of the late king now suggested to Gloucester a means of vilifying the queen dowager and her descendants. He did not hesitate to malign his own mother, affirming that the resemblance of Edward IV. and of the duke of Clarence to notorious gallants was a sufficient proof of their spurious birth, and that the duke of Gloucester alone, of all his sons, appeared by his features and countenance to be the true offspring of the duke of York. He openly denied the title of Edward V., who meanwhile, with his brother, languished in prison. The precise time and the details of the death of these princes are unknown. A conspiracy had been set on foot for their liberation during the first year of the usurper's reign, when it was announced that they were no longer alive. Sir Thomas More's account, which was collected from the confession of the murderers in the next reign, is as follows: that Richard had in vain tampered with the governor of the tower, Brackenbury, to put them to death, but found a ready instrument for the execution of his purpose in Tyrrel, his master of horse; that Tyrrel was despatched with a commission to receive the keys of the tower for one night, and during that night he watched without while one of his grooms, accompanied by a notorious assassin, entered the sleeping room of the princes, stifled them with feather beds and pillows, and buried their bodies at the foot of the staircase. The testimony of More is almost contemporaneous with the event itself, and is confirmed by the honors which were certainly conferred upon

the alleged murderers. In the reign of Charles II., when alterations were made in the tower, there was found at the foot of an old stairway a heap of decayed bones which were supposed to be those of two boys. They were removed by royal command to Westminster abbey, where an inscription, beginning *Ossa desideratorum diu et multum quesita*, was placed upon the monument.

EDWARD VI., third king of England of the Tudor dynasty, born Oct. 12, 1537, ascended the throne in 1547, and died July 6, 1553. The son of Henry VIII. and Jane Seymour, he was little cared for by the three stepmothers whom he had in quick succession; but at the age of six years, being intrusted to the learned masters Anthony Cooke and John Cheke, he made progress in philosophy, divinity, Greek, and Latin. Henry VIII. appointed in his will a council of executors to exercise the royal authority during the minority of his son, who at their first meeting, fearing that the government would lose its dignity for want of some head to represent the royal majesty, bestowed upon Edward Seymour, now created duke of Somerset, or allowed him to assume, the titles of governor of his majesty, lord protector of all his realms, and lieutenant general of all his armies. Sir Thomas Seymour, the brother of Somerset, was created Baron Seymour of Sudley, and appointed lord high admiral. The government was almost entirely Protestant, and its first object was to complete the religious revolution and establish a church independent of the see of Rome. The statute of the six articles was repealed, prisoners under it were released, and exiles were recalled. Preaching, which had been rare in Catholic times, was enforced by visitors despatched throughout the kingdom, who were authorized to require that four sermons be preached every year in every church against the papacy. Images, which Luther had tolerated as aids to devotion, and of which Cranmer vindicated a moderate use, became objects of dislike, and were torn down in places where they had been honored by pilgrimages and offerings. The English Bible, with Erasmus's commentary on the gospels, was placed in every church for the use of the people. In the first parliament the statutes of Richard II. and Henry IV. against the Lollards were repealed, together with all the acts in matters of religion passed under Henry VIII., except those directed against the papal supremacy. The uniformity of public worship was established, and all ministers were enjoined to use only the "Book of Common Prayer." The English clergy were emancipated from compulsory celibacy, though it was recommended to them "to live separate from the bond of marriage, for their own estimation, and that they might attend solely to the ministration of the gospel." There were as yet no Protestant nonconformists, but all persons were commanded to attend public worship under pain of ecclesiastical censures,

of six months' imprisonment for the first offence, twelve for the second, and confinement for life for the third. Bonner, bishop of London, Gardiner, bishop of Winchester, and several others, were deprived of their sees because they could not keep pace with the reformatory movement. The first step toward religious liberty was a distinction, recognized practically though not by canon, between what were supposed to be the essential and the unessential parts of Christianity, and only offences against the former were liable to deadly persecution. Thus, no Roman Catholic suffered death for religion in this reign; but Joan Bocher, commonly called Joan of Kent, was burned for an unintelligible heresy, which denied something, though her words vainly struggled to explain what, concerning Christ. Van Parris, a Dutchman, was also burned for denying the divinity of the Saviour. Among civil occurrences in this reign, the first of importance, after the settlement of the government, was the expedition of Somerset into Scotland to compel the marriage of Mary, the young queen of Scots, to Edward, according to a previous treaty. A bloody encounter, begun between the Scottish and English cavalry at Falside, Sept. 9, 1547, was continued the next day between the entire armies at Pinkie, and ended in the victory of the English protector. But he was quickly called home by machinations against him, and Mary was sent to France. His brother and rival, Lord Seymour, was committed to the tower early in 1549, and a bill attainting him was brought into the house of lords. This bill, by the influence of Somerset, who was present in the house to encourage it, was passed unanimously within three days; and Seymour, without an opportunity to defend himself or to confront his accusers, was beheaded on Tower hill, March 20. During the next summer formidable insurrections broke out in various parts of the kingdom. The depreciation of the currency during the last reign had been followed by an advance in the price of commodities; at the same time the demand for labor had been lessened and wages reduced. The new owners of abbey lands had enclosed many of the fields which had formerly been allotted for the common use of the poor inhabitants, and their rapacity was contrasted with the indulgence of the monks, who had often been the most lenient of landlords. There were armies of insurgents in several counties, the largest and most violent being in Cornwall, where a tanner named Kett encamped near Norwich at the head of 20,000 men. He repulsed the marquis of Northampton, but was at length defeated and hanged with his principal associates. The protector had incurred odium by what was termed his feeble administration during this rebellion, and also by his lavish expenditures upon his magnificent palace of Somerset house. He had wavered and almost given sanction to the demands of the populace when they were in arms against the royal au-

thority; and had become from a simple knight with a slender fortune the possessor of more than 200 manors and parcels of land. The discontented lords, directed by Dudley, earl of Warwick, gradually withdrew from court and met in London with bodies of their retainers. The protector, as soon as he received intelligence of their movements, took the king with him to Windsor, and called by proclamation on all faithful subjects to join him at Hampton court in arms for the protection of the royal person against a conspiracy. Multitudes of the common people, but scarcely a gentleman, obeyed his summons, and his cause was rendered desperate when the council declared against him. The king was obliged to sanction the vote for his deposition, and he was brought to London and incarcerated in the tower, Oct. 14, 1549. Warwick dissembled for the moment his purpose concerning the prisoner, and was obliged by his position, though a secret Catholic, to favor the cause of the reformation, and, though a rancorous enemy of Somerset, soon to set that nobleman free, and to give his own son in marriage to Somerset's daughter. But when Warwick had received the office of lord high admiral, had been raised to the dignity of duke of Northumberland, had become the undisputed chief of the government, and had annihilated the power of Somerset, he was able to proceed further against that duke, who was again committed to the tower in 1551, was convicted of felony, and executed on Tower hill, Jan. 22, 1552. Warwick next persuaded Edward to make a new settlement excluding his sisters from the succession to the throne, and giving the nomination to Lady Jane Grey, who had been his playmate and companion in studies. Edward sank rapidly after this, and died in the 16th year of his age and the 7th of his reign. His accomplishments were such as to surprise the famous Italian physician Jerome Cardan, who visited him in his last sickness; and for his diary and other compositions he is included by Walpole in his list of royal authors. He was succeeded by his sister Mary, after Lady Jane Grey's nominal reign of a few days.—The literary remains of Edward VI., edited with historical notices and a biographical memoir by John Gough Nichols, were printed in 1859, for the Roxburghe club (2 vols., London).

EDWARD, prince of Wales, surnamed the Black Prince, from the color of his armor, eldest son of Edward III. and Philippa of Hainaut, born at Woodstock, June 15, 1330, died June 8, 1376. In his 16th year he accompanied his father in his invasion of France, and he held the nominal command of the largest and most actively engaged division of the English forces in the battle of Crécy. Among the slain was John of Luxemburg, the blind king of Bohemia, whose crest of three ostrich feathers, with the motto *Ich dien* (I serve), was adopted by the prince of Wales, and has always been

borne by his successors. In 1356 he gained the victory of Poitiers, in which the French King John was taken prisoner. He returned to England in 1357, the king of France on a splendidly caparisoned charger forming the principal ornament of the cavalcade with which he entered London. In 1361 the king of England united all his dominions between the Loire and the Pyrenees into one principality, and bestowed it upon the Black Prince, with the title of prince of Aquitaine. There Pedro the Cruel took refuge from Castile, and young Edward undertook to replace him on his throne. He marched through the valley of Roncesvalles and by Pamplona to the frontiers of Castile, met and defeated Henry of Trastamare on the plains between Navarrete and Najera, was disappointed of the reimbursements which had been stipulated, and returned into Guienne with an exhausted treasury and a shattered constitution. To defray the expenses of his court, perhaps the most magnificent in Europe, and to fulfil his contracts with the troops that had followed him to Spain, he imposed taxes which made him unpopular with his barons. Summoned in 1369 to answer before King Charles of France to the complaints of his vassals, he replied that he would obey, but at the head of 60,000 men. He appeared in the field, but the French generals avoided an engagement and garrisoned their strong places. He laid siege to Limoges, captured it and reduced it to ashes, and massacred the inhabitants. This was the end of his military career, and by the advice of his physicians he returned to England, where he lingered for six years. The Black Prince is portrayed by contemporary writers as the most heroic of princes. He married his cousin Joan, countess of Kent, famed for her beauty, by whom he left one son, Richard, who succeeded Edward III. as king.

EDWARDES, Sir Herbert Benjamin, an English soldier and author, born at Frodesley, Shropshire, Nov. 12, 1819, died Dec. 23, 1868. He studied at King's college, London, entered the East Indian service, was wounded in the battle of Moodkee, December, 1845, and participated in the victory of Sobraon, February, 1846. When Moolraj, in April, 1848, stirred up a rebellion of the Sikhs, it was the courage and skill of Lieut. Edwardes that saved the British power in the Punjab. With Col. Cortlandt he moved down the W. bank of the Indus at the head of 7,000 men, and crossed the stream with a small body of infantry to attack the enemy. He was confronted by a force of 12,000 men, and after a hard-fought battle, memorable for a gallant charge of the mounted British officers upon the Sikh front, the insurgents were routed by the opportune arrival of Col. Cortlandt, and made their way to Mooltan. In the subsequent siege of that city and its assault he gained new laurels, but lost his right hand by the accidental discharge of a pistol. He finally reached the rank of major general. After the war he visited England, married, and pub-

lished "A Year on the Punjaub Frontier" (2 vols. 8vo, London, 1851). He afterward returned to India, and in 1864 was appointed lieutenant governor of the Punjaub. His "Life of Sir Henry Lawrence" was completed by Herman Merivale (London, 1872).

EDWARDS, I. An unsettled S. W. county of Texas; area, 1,225 sq. m. It is chiefly noted for its mountain cedar, cold springs, and large rocks. **II.** A S. E. county of Illinois; area, 200 sq. m.; pop. in 1870, 7,565. Bon Pas creek flows along its E. border, and the Wabash touches it on the S. E. The surface is occupied by forests and fertile undulating prairies. The chief productions in 1870 were 122,703 bushels of wheat, 352,371 of Indian corn, 129,152 of oats, 14,522 of potatoes, 7,374 tons of hay, 48,703 lbs. of wool, and 133,150 of tobacco. There were 2,952 horses, 2,045 milch cows, 2,900 other cattle, 14,401 sheep, and 13,274 swine. Capital, Albion.

EDWARDS, Amelia Blandford, an English novelist, born in 1831. She early exhibited literary and artistic tastes, and in 1853 began to contribute to periodicals. She has written an "Abridgment of French History," a school history of England, a volume of ballads, and several books for children, the most successful of which are "The Little Marquis" and "The Story of Cervantes." But she is best known by her novels: "My Brother's Wife" (1855), "The Ladder of Life" (1857), "Hand and Glove" (1859), "Barbara's History" (1864), "Half a Million of Money" and "Miss Carew" (1865), "Debenham's Vow" (1870), and "Monsieur Maurice and other Tales" (1873).

EDWARDS, Bela Bates, an American author and editor, born in Southampton, Mass., July 4, 1802, died in Georgia, April 20, 1852. He graduated at Amherst college in 1824, entered the seminary at Andover in 1825, in 1826 was appointed tutor at Amherst, and in 1828 was chosen assistant secretary of the American education society, and performed the duties of this office till 1833. His literary and editorial labors were very great and important. From 1828 to 1842 he edited for the education society the "American Quarterly Register." In 1833 he established the "American Quarterly Observer," which, after three volumes, was united with the "Biblical Repository" of Prof. Robinson, which he edited from 1835 to 1838. Of the "Bibliotheca Sacra" he was the editor from 1844 to 1852. In 1837 he was appointed professor of Hebrew in the seminary at Andover; and in 1848 of Biblical literature, which office he held till his death. He prepared the "Eclectic Reader," "Biography of Self-taught Men," "Memoirs of E. Cornelius" (1842), a volume on the Epistle to the Galatians, and the "Missionary Gazetteer" (1832). A selection of his sermons, lectures, and addresses, with a memoir by Prof. Park (2 vols. 12mo), was published in Boston in 1853.

EDWARDS, Bryan, an English historian, born in Westbury, Wiltshire, May 21, 1743, died

July 15, 1800. After acquiring a good English education at Bristol, he emigrated to Jamaica in 1759, where a rich uncle gave him the means of completing his studies, and made him his heir. He became a prominent member of the colonial assembly, and published in 1784 a pamphlet against the restrictions laid by government on the trade between the West Indies and the United States. He afterward went to Santo Domingo, and collected materials for his "Historical Survey of the French Colony" in that island (4to, London, 1797), which was incorporated in the author's best known work, "The History, Civil and Commercial, of the British Colonies in the West Indies" (2 vols. 4to, London, 1793; 3d ed., 3 vols. 8vo, 1801; 5th ed., with a continuation to 1796, 5 vols. 8vo, 1819). This work bears a high character, and gives very minute and varied information. Mr. Edwards returned to England, and from 1796 till his death represented Grampound in parliament.

EDWARDS, George, an English ornithologist, born in Stratford, Essex, about 1693, died July 23, 1773. He was brought up to trade, but developed a taste for natural history and antiquities, and at the close of his apprenticeship visited Holland, Norway, and other parts of Europe, in prosecuting his favorite researches. The fruit of his labors appeared in his "Natural History of uncommon Birds, and of some rare and undescribed Animals" (4 vols. 4to, London, 1743, '47, '50, and '51); to which three more volumes were added in 1758, '60, and '64, called "Gleanings of Natural History." This exceedingly valuable work contained numerous plates, with descriptions in French and English of more than 600 subjects. In its original form it is scarce, but several partial editions and abridgments have been published. He left a work entitled "Elements of Fossillology," which appeared in 1776.

EDWARDS, John, an English divine, born in Hertford, Feb. 26, 1637, died in Cambridge, April 16, 1716. He graduated at Cambridge in 1661, and took charge of Trinity church there, thence removed successively to Bury St. Edmund's, to Colchester, and back to Cambridge. In 1699 he was made doctor of divinity; and from this time he became a voluminous writer, showing himself a subtle, able, and learned polemic. He was a very earnest Calvinist, and from his abhorrence of Arminianism connected it with popery. His most important works are "Veritas Redux, or Evangelical Truths Restored;" "Inquiry into four remarkable Texts;" "Discourse concerning the Authority, Style, and Perfection of the Books of the Old and New Testaments;" "Survey of the several Dispensations of Religion;" "Answer to Dr. Whitby's Five Points;" "Animadversions on Dr. Clarke's Scripture Doctrine of the Trinity;" and "*Theologia Reformata*: the Body and Substance of the Christian Religion." He wrote also several treatises against the Socinians.

EDWARDS, Jonathan, an American divine and metaphysician, born at East Windsor, Conn., Oct. 5, 1703, died at Princeton, N. J., March 22, 1758. He was an only son, with ten sisters, four of whom were older than himself. His father and his mother's father were eminent ministers; he sprung directly from John Warham, the west of England minister who reached America a week or two before Winthrop, settled first in Dorchester, and then with a part of his flock removed to Windsor. He was trained by his father and his elder sisters for college and to habits of careful study and analysis. The community in which he lived was eminently religious, and before he was ten years old his religious sensibilities were strongly aroused. His childhood was troubled with anxious doubts as to the divine sovereignty. At the age of ten he wrote a paper ridiculing the idea that the soul is material. He early showed quickness and accuracy of observation; when twelve years old he sent to a European correspondent of his father an account "of the wondrous way of the working of the spider" in the forest, whose habits he had watched. In September, 1716, he entered Yale college. He gained a good name for "his carriage and his learning;" but in his scanty opportunities the range of his learning was very limited. He knew little of classic literature; the best impulse to his mind was given by Locke's "Essay on the Human Understanding," which he read with delight. But he was quickened, not subdued or mastered, by Locke's system, which turned him to speculative activity. He inclined to that system which in Europe had found its representatives in Malebranche and Leibnitz; and, probably from citations, something of Plato's theory of ideas, and something of the doctrine of Cudworth's "Intellectual System," infused themselves into his reflections. When about 15, in opposition to Locke, he denied the possibility of adding to matter the property of thought, and held that "everything did exist from all eternity in uncreated idea;" that "spirit or mind is consciousness and what is included in consciousness;" that "truth is the agreement of our ideas with the ideas of God;" that "nothing has a proper being but spirit;" that "matter is merely ideal;" that "the objects of the external senses are but the shadows of being;" that "the universe exists nowhere but in the divine mind." His speculations have sometimes a startling resemblance to those of Spinoza. The latter calls thought and extension the "attributes of God," and ascribes being to God alone; Edwards wrote that "space is God." In one of his latest works he says of God, "He is all and alone;" "the infinite, universal, all-comprehending entity." In his youth he said, "God and real existence are the same; God is, and there is none else." While a collegian he argued out for himself his theory of the will and his theory of virtue. One thing more was wanting to shape his

course. He counted himself still among the unregenerate; but after an illness in his last year in college, when not yet 17, how or by what means he could never tell, "his past convictions" were overcome, and he had no more doubts of "God's absolute sovereignty and justice with respect to salvation and damnation." Now he had found the purpose of his life; his speculative opinions and his religious faith were unalterably formed. He had no less than Locke a disposition to show the harmony between reason and religion, the faculties of man and the dogmas of the true faith; but from the first he repelled the materialist philosophy; and while he never came forward as the express combatant of Locke, it became from his early youth the object of his earthly career to combat the results of Locke's philosophy in its application to the sources of knowledge, the science of morals, and theology. His sense of divine things would often of a sudden kindle up "a sweet burning in his heart." He gave an account of his experience to his father, and united with the church. For two years after he took his degree he remained in New Haven as a student for the ministry; and in August, 1722, he was selected to preach in a Presbyterian church in the city of New York. Here he remained eight months, and here on Jan. 12, 1723, he made anew a solemn dedication of himself to God. In April, 1723, he returned home, and at his father's house in East Windsor continued his studies, made with the pen in hand. Here he finished a series of 70 resolutions, in regard to which he humbly entreated God by his grace to enable him to keep them all: to act always for the glory of God, for the good of mankind in general; to lose not one moment of time; to live with all his might while he did live; to let the knowledge of the failings of others only promote shame in himself; to solve as far as he could any theorem in divinity he might think of; to trace actions back to their original source; to be firmly faithful to his trust; to live as he would if it were but an hour before he should hear the last trumpet; to strive every week for a higher and yet higher exercise of grace; "to keep a benign aspect, and to let there be something of benevolence in all his speech." In September, 1723, several congregations invited Edwards to be their minister; but he declined every proposal, reserving two years more for study. In June, 1724, he became tutor in Yale college. In the summer of 1726 he was invited to become the pastor at Northampton, as the colleague of his grandfather, Solomon Stoddard; and on Feb. 15, 1727, he was ordained to his office. On July 28 he married Sarah Pierrepont, daughter of a minister at New Haven. In February, 1729, the senior pastor died, and the young minister was left alone. It was his habit to rise early, and study during the whole day. He made no visits unless sent for by the sick or the sorrowing, but encouraged persons under religious

impressions to come to consult him. In spite of this comparative seclusion, and in spite of a weak and infirm constitution, he was an acceptable pastor, and his fame as a preacher was very wide. The little exercise which he took consisted in solitary walking or in rides on horseback in the lonely woods. In July, 1731, he was prevailed upon to deliver the Thursday lecture in Boston; and his discourse was printed and greatly approved. It was his habit to write out his thoughts with care, but to utter himself fluently without regard to his notes. His voice, though not strong, was clear and distinct; and his manner, though he used little of gesture, showed his own fervor and moved the hearts of his hearers. The Arminian doctrine seemed to him of the most dangerous practical tendency, and in 1734 he began to preach on justification by faith alone. His preaching was followed by a wonderful revival of religion, exceeding everything that had been known at any time in any part of the country. On this occasion he printed a sermon on "A Divine and Supernatural Light imparted to the Soul by the Spirit of God," and he wrote a narrative of this great awakening, which was printed in England, and republished in Boston, with some doctrinal discourses against the Arminians. The revival began to extend far and wide through the New England colonies, having a permanent influence on the character of the people and their conduct in events that were soon to come. Tradition still keeps in memory the wonderful effect of Edwards's sermon at Enfield on sinners in the hands of an angry God. He wrote "Thoughts on the Revival of Religion," and published in 1746 his "Treatise concerning Religious Affections." His life was now destined to meet with seemingly one of the saddest of afflictions. Edwards noticed among his people levities of manner, consequent as it seemed on reading books which a severe morality could not approve, and he invoked the attention of his church to the subject. The church disapproved of the scandal which would follow an inquiry, and let the matter drop. Under the lax discipline of his predecessor the church had been filled up with persons who, though outwardly well behaved, were not strictly religious. Calvin and the Congregationalists admitted to the communion only those who professed personal religious convictions, and baptized only the children of communicants. On this system the churches of Massachusetts and Connecticut were founded. But the Roman Catholic and the Lutheran and Anglican churches baptized all children born within their pale; and the influence of their example made the New England people generally desire to secure the ordinance of baptism for their offspring, and the "half-way covenant" was adopted. Edwards desired to enforce the old rule, which in the Northampton church had never been abrogated, and found himself at variance with the church. He held

that experimental piety should go before admission to full communion; the church held that the Lord's supper is a converting ordinance. Edwards was overborne by the majority. He proposed to deliver a course of lectures on the subject, and they refused him their consent; and on June 22, 1750, he was forced to resign. His friends in Scotland invited him to come over and establish himself in that country; Samuel Davies of Virginia entreated him to remove to that state, offering to surrender to him his own parish, and pleading that he and he only had weight enough by his representations in Great Britain to stop the illiberal oppression of Presbyterians by the governors of the Old Dominion. But he accepted an offer from the agent of the London society for propagating the gospel, to become a missionary to the remnant of the Housatonic Indians at Stockbridge. The handful of white settlers that had gathered round the tribe also asked him to become their pastor. His trifling income was slightly augmented by the delicate handiwork of his wife and daughters, which was sent to Boston to be sold. At Northampton Edwards had been the centre of a wide circle of influence, visited by many guests, consulted by many churches; at Stockbridge all his preaching to the Indians was uttered extempore, without notes, aided by an interpreter; and when he was once established in a house of his own, he found himself possessed of more leisure than he had ever before enjoyed. The next six years were given to uninterrupted study. The narrow apartment that formed his workroom found him early and late at his desk; he scarcely shared the meals of his family. The development of the views which had long engaged his mind formed the chief entertainment and delight of his life. The main point in the discussion between Arminians and Calvinists had been carefully considered by him from the time he was 15 years old, and he had kept minutes of his thoughts during the intervening period. He now finished his "Inquiry into the Freedom of the Will," and published it in 1754. After a half year's illness he completed a dissertation on "God's Last End in the Creation of the World," which is a picture of his own character, reasoning, and mind. He also wrote at this period his dissertation on the "Nature of True Virtue," and his essay on "Original Sin," and planned a comprehensive work on Christian theology in the form of a history, a revision and completion of the history of redemption which he had written at Northampton, to be carried on with regard to all three worlds, heaven, earth, and hell. Plans of other treatises crowded also upon his mind. These studies were interrupted by the death of his son-in-law, President Burr of Princeton college, and Edwards was called to succeed him. He kindled by his presence and his words the liveliest interest among the students, and on Feb. 16, 1758, was installed as president. The

smallpox was prevailing in the neighborhood, and he was inoculated; but the disease took an unfavorable turn, and he died 34 days after his installation, at the age of 54. In 1872 his descendants erected to his memory at Stockbridge a monument of red granite, 25 ft. high.—In considering the writings of Jonathan Edwards, the first thing to be borne in mind is his unquestioning acceptance of the truth of the Holy Scriptures, of every event recorded there, every miracle, and every prophecy; the actual fall of man, the incarnation, death, resurrection, and ascension of Christ. The next is, the intensity of his attachment to the system of Calvinism as opposed to that of Arminianism. These points being premised, the characteristics of all that Edwards has written are threefold. He looks always to establish the reasonableness of his views. The doctrine of a divine incarnation, for example, approves itself, as he thought, to human reason; and he cites in proof the authority of Greeks and Romans, the most philosophical nations of the world, and refers to the *anima mundi* of Blount and the pantheism of Spinoza. He scoffs at the pretensions to greater liberality of the Arminians, and puts reason and common sense on the side of orthodoxy. He thought there was no need that the strict philosophic truth should be at all concealed. "The clear and full knowledge of the true system of the universe will greatly establish the doctrines which teach the true Christian scheme of divine administration in the city of God." Least of all would Edwards give up the individual right of free inquiry, for he says: "He who believes principles because our forefathers affirm them, makes idols of them; and it would be no humility, but baseness of spirit, for us to judge ourselves incapable of examining principles which have been handed down to us." He knows no scheme of Christianity that is the fruit of time; the divine administration began from eternity and reaches forward to eternity. The third great feature of his mind is its practical character. His system has in view life and action; he puts aside all merely speculative questions, and while he discusses the greatest topics, it is only because of his overwhelming consciousness of their important bearing on conduct and morals. He moves in the real world, and brings theology down from the dim clouds of speculation to the business and the bosoms of the universal people. It is a strange misconception about Edwards, that he drew his philosophy from Locke. In the want of books, the essay of Locke trained him to philosophical meditation; but his system was, at its foundation and in every part, the very opposite of the theory of Locke. On the subject of the origin of ideas he accords with Leibnitz. The doctrine that all truth is derived from sensation and reflection he discards. The knowledge of spiritual truth he considers "a new principle," "the divine nature in the soul." "It is the Spirit of God that gives

faith in him," were the words of his sermon at the Boston lecture in 1731; and three years later he enforced at large that it is a doctrine of reason that "a divine supernatural light is immediately imparted to the soul by the Spirit of God." He teaches that knowledge of spiritual truth cannot be derived from the senses; it is a wisdom not earthly or natural, but descending from above; "it is the image and participation of God's own knowledge of himself." In like manner he finds the idea of causality "implanted by God in the minds of all mankind." As a consequence, the contrast of Edwards with Locke and those who came after him appears equally in the different manner in which they sought to establish the truth of Christianity. The disciples of Locke's philosophy cling to the historical evidence from miracles as the principal proof of the Christian religion. Edwards, on the contrary, laid down the principle that "no particular sort of outward representations can be any evidence of a divine power." "Unless men may come to a reasonable, solid persuasion and conviction of the truth of the gospel, by the internal evidences of it, by a sight of its glory, it is impossible that those who are illiterate and unacquainted with history should have any thorough and effectual conviction of it at all." "It is unreasonable to suppose that God has provided for his people no more than probable evidences of the truth of the gospel. It is reasonable to suppose that God would give the greatest evidence of those things which are greatest, and the truth of which is of the greatest importance to us. But it is certain that such an assurance is not to be attained, by the greater part of them who live under the gospel, by arguments fetched from ancient traditions, histories, and monuments."—The theory of Edwards respecting providence corresponded with that of Leibnitz. To him the laws of nature were not established and left to themselves, but were the methods according to which God continued his "immediate influence." "His preserving created things in being is equivalent to a continued creation." The presence of moral evil, the depravity of human nature, he considered from two points of view. He raised his mind to the contemplation of God as the Creator, and had then no theory to offer for man's depravity but the divine will. He never presumed to ask Almighty God why it was so. But to those who questioned this absolute sovereignty, and rejected it as a doctrine full of horror, he made a twofold answer, not as finding excuses for the Creator, but subjectively as shutting the mouth of cavillers: First, that man's depravity is an unquestionable fact; that through the medium of his senses and merely animal organization man can attain to no knowledge of God and no spiritual perfection. Secondly, he set forth the unity of the race; its common constitution as branches from one root, forming one complex person, one moral whole;

which is the view of Augustine and Calvin. This view also had a most important bearing on the theory of morals. The momentous question of man's relation to moral evil, and the way of his escape from it, formed one of the chief objects of Edwards's thoughts during his whole life. "Men in a very proper sense may be said to have power to abstain from sin, because it depends on the will;" and if they will not, the defect is in themselves; yet a man's evil disposition may be as strong and immovable as the bars of a castle. The law of causality extends to every action. Liberty consists in the power of doing what one wills, not in any power of willing without a motive. The will always follows the greatest seeming good; and what shall seem to a man the greatest good depends on the state of his soul. Liberty is not in the act, but in the man; and if a depraved nature is to abstain from sin, it can only be effected by a change of heart. This theory Edwards asserted by an appeal to the facts of universal experience, and by a thorough analysis of the complex cause of action. In his essay on the "Nature of Virtue" he finds it to consist in love; not in love as resting complacently on its objects, but in love as the ruling motive of the will; love in action, benevolence. And this love is not for self; the doctrine of Edwards is the intensest protest against the theory of self-love. Taking Christ's summary of the law under two commandments of love to God and love to one's neighbor, he finds a general term which includes both God and man in "Being," and he therefore defines virtue as the "love of Being." Thus virtue implies the love of God with all the soul, for God is the Being of beings, "in effect, Being in general." The love to universal Being includes all being, each in its degree, according to its amount of existence; active love for the good of the world of mankind before the love of country, of country before that of a single city, of a city before a family, of the family before the individual, of the individual only in subordination to the great system of the whole. The theory is the opposite of that which makes self-love the foundation of moral order. It does not weaken the bonds of family affection; only the love of wife or husband, parent or child, must not be the paramount motive. In this light the doctrine of the oneness of the race, which Edwards asserted with great clearness and force, gains new significance.—The ethical theory of Edwards is cosmical. It is universal history resting on the principle of the redemption of the world, decreed from all eternity; the gradual progress and advancement of the race through the presence of the Divine Word and its ever approaching triumph over all enemies. Events seem confused like the work of an architect, who employs many hands in many kinds of labor at once; but a knowledge of the design removes all appearance of confusion; and so the design of the Divine Word in redemption

gives unity to the history of all the nations of the earth. The development of this idea employed the latest thoughts of Edwards, though his "History of Redemption" is only a sketch of the great work which he planned.—Edwards makes a turning point in the intellectual, or, as he would have called it, the spiritual history of New England. New England and New Jersey, in the age following him, applied more thought to the subject of religious philosophy and systematic theology than the same amount of population in any other part of the world; and his influence is discernible on every leading mind. Bellamy and Hopkins were his pupils; Dwight was his expositor; Smalley, Emmons, and many others were his followers; through Hopkins his influence reached Kirkland, and assisted in moulding the character of Channing. Edwards sums up the old theology of New England, and is the fountain head of the new.—There are several lives of Jonathan Edwards. The most interesting is that by Hopkins, who was his pupil; the fullest is that by Sereno Edwards Dwight. There have been two editions of his works in England, one in 8 vols. 8vo, and one in two compact volumes. The American editions are to be preferred. One was published at Worcester, Mass., edited by Samuel Austin, in 1809, in 8 vols. The New York edition is by Sereno E. Dwight, in 10 vols. 8vo, of which the first contains the life. There is also a later and convenient New York edition in 4 vols.

EDWARDS, Jonathan, president of Union college, Schenectady, N. Y., son of the preceding, born in Northampton, Mass., May 26, 1745, died in Schenectady, Aug. 1, 1801. At the age of six he went with his parents to Stockbridge, where there was but one school for both Indians and whites, of the latter of whom there were so few that he was in danger of forgetting the English tongue. He thoroughly learned the language of the Stockbridge Indians, and in later years published a treatise on the subject. In his 10th year he was sent by his father with the Rev. Gideon Hawley among the Six Nations, that he might also learn their language and become qualified to be a missionary among them. Here he made rapid progress; but owing to the disturbances of the French war, he soon returned to Stockbridge. In 1761 he entered the college at Princeton, N. J., where he graduated in 1765. He studied divinity with Dr. Bellamy, and in 1766 was licensed to preach. In 1767 he became tutor in the college at Princeton. In 1769 he was ordained as pastor of the church in White Haven, in the town of New Haven, Conn., where he continued till May 19, 1795. Resigning his charge, mainly on account of difference in doctrinal views between himself and some of his people, he was settled in 1796 as pastor of the church in Colebrook, where he gave much time to study, and to an extensive correspondence with learned men in America and in Europe. In May, 1799, he was

elected president of Union college, but only lived two years after his inauguration. His complete works, edited with a memoir by his grandson, the Rev. Tryon Edwards, D. D., were published in 2 vols. at Andover in 1842.

EDWARDS, Justin, an American clergyman, born in Westhampton, Mass., April 25, 1787, died at Virginia Springs, July 23, 1853. He graduated at Williams college in 1810, settled in the ministry at Andover in 1812, removed to the Salem street church, Boston, in 1828, and in 1829 resigned this charge to become secretary of the American temperance society, in the service of which he was engaged for seven years, delivering lectures and addresses, and preparing the "Temperance Documents." After this, he was for six years president of the Andover theological seminary. He wrote the "Sabbath Manual," and spent four years in preparing a brief commentary on all the New and part of the Old Testament, for the American tract society, before finishing which he died. He was the author of several valuable tracts, some of which have had a wide circulation. Of his "Temperance Manual" and of the different parts of his "Sabbath Manual" many hundred thousand copies have been printed. A memoir of his life and labors was published by the American tract society in 1855.

EDWARDS, Milne. See MILNE-EDWARDS.

EDWARDS, Richard, an English dramatist, born in Somersetshire in 1523, died about 1566. He was educated at Corpus Christi college, Oxford. His "Damon and Pythias" was the first English tragedy on a classical subject, and was acted before the queen at Oxford about 1566. All his other dramas are lost. He wrote several minor poems, of which *Amantium Iræ* has been often reprinted.

EDWARDS, Tryon, an American clergyman and author, grandson of the younger Jonathan Edwards, born in Hartford, Conn., Aug. 7, 1809. He graduated at Yale college in 1828, studied law in New York and theology at Princeton, and settled in the ministry at Rochester, N. Y., in 1834. He removed in 1845 to New London, Conn. In 1832 a prize tract on Sabbath schools appeared from his pen, and he has from that time contributed constantly to the religious press. Among his publications are an address delivered at Williams college in 1841, entitled "Christianity a Philosophy of Principles;" a memoir of the younger President Edwards, published with his complete works (1842); "Self-Cultivation" (1843); and a memoir of Dr. Bellamy, published with his complete works (1850). He has edited a volume entitled "Charity and its Fruits," from the MSS. of the elder President Edwards, and several collections designed especially for domestic culture, as "Select Poetry for Children and Youth" (1851), "Jewels for the Household" (1852), "The World's Laconics" (1852), and "Wonders of the World" (1855). He was long editor of the "Family Christian Almanac."

EDWIN, king of Northumbria, born about 586, ascended the throne in 617, and died in 633. He was an infant when at the death of his father, Ælla, king of Deira, the throne was usurped by his brother-in-law, Ethelfrid, king of Bernicia, who in 593 united the two kingdoms under the name of Northumbria. Edwin was placed by his friends under the protection of Cadvan of North Wales. The British prince was assailed by the Northumbrian, and the two armies met in the vicinity of Chester. Victory decided for Ethelfrid; a body of monks who had stationed themselves on a neighboring hill to deprecate the success of the invader were put to the sword, and the great monastery of Bangor, containing 2,100 monks, was demolished. Edwin then wandered through the different principalities of the Britons and Saxons, till he found an asylum at the court of Redwald, king of the East Angles. Redwald made war on Ethelfrid; the armies met in 617 on the banks of the Idle, in Nottinghamshire; Ethelfrid was defeated and slain, and Edwin without further opposition ascended the throne. The martial genius of Edwin raised Northumbria to preëminence among the Anglo-Saxon states. The islands of Anglesea and Man became subject to his authority, all the princes of the Britons paid him tribute, and among the Saxon kings Eadwald of Kent alone retained a nominal independence. So inflexible was his administration of justice, that in his days it was a common saying that a woman or a child might openly carry everywhere a purse of gold without danger of robbery. The chief event of his reign was the introduction of Christianity into the kingdom of Northumbria. He married Ethelburga, a princess of Kent, daughter of that Bertha by whose influence the king and people of Kent had been already converted to Christianity. Yet neither the entreaties of the young queen, the arguments of the learned bishop Paulinus, nor the letters and presents of Pope Boniface V., could for a long time turn him from the worship of his fathers. He consulted alternately the priests on either side, revolved in solitude their opposite arguments, assembled the witenagemote for consultation, and at last avowed himself a convert, and was followed by his people. Edwin perished in a disastrous battle with the combined armies of Penda, king of Mercia, and Ceadwalla, king of the Britons, who had raised the standard of rebellion, and marched into Yorkshire; and the kingdom was soon after recovered by Oswald, son of Ethelfrid.

EDWY, surnamed the Fair, a king of the Anglo-Saxons, son of Edmund I., and successor of his uncle Edred, born about 938, ascended the throne in 955, and died at the close of 958. He was passionate and dissolute. Having on the day of his coronation retired from the banquet to the apartment of a young princess named Elgiva, he was violently taken back to the table by St. Dunstan, whom he then ban-

ished from the kingdom. Archbishop Odo broke with an armed force into the villa where Elgiva resided, defaced the beauty of that lady with brands, and exiled her to Ireland; but she returned to England, where she suffered hamstringing and died. It is in dispute among historians whether Elgiva, who was within the prohibited degrees of consanguinity, was the wife or the mistress of Edwy. The English favored the ecclesiastics rather than the king, and a rebellion broke out under Edgar, a younger brother of Edwy, who was chosen king by the Mercians. Edwy was obliged to flee beyond the Thames, and the civil war was ended in 957 by a general meeting of the thanes, who determined that that river should be a boundary between the dominions of the two brothers. Edwy governed Wessex and Kent till his death.

ECKHOUT, or **Eckhout**, **Gerbrant van den**, a Dutch painter, born in Amsterdam, Aug. 19, 1621, died there, Sept. 22, 1674. He was a pupil of Rembrandt, and in some measure successful in imitating his manner, especially in the early part of his life. He excelled chiefly in portraits, and these as well as his historical pictures abound in the best collections of Holland, while several are to be found in Germany.

ECCLOO, or **Eccloo**, a town of Belgium, in the province of East Flanders, 11 m. N. W. of Ghent; pop. in 1866, 9,564. It has an active industry and commerce in woollen and cotton fabrics, hats, tobacco, and oil, and is an important grain market.

EEL, a name applied to several malacopterous fishes of the families *anguillidae*, *congeridae*, and *muraenidae*, especially to the typical genera *anguilla* (Cuv.), *conger* (Cuv.), and *muraena* (Thunb.). From their snake-like appearance, and the absence of ventral fins or posterior limbs, they have been called anguiform *apodes*; they all have the body more or less elongated and cylindrical, no ribs in the skeleton, a caecal stomach, and simple not-jointed fin rays. In the genus *anguilla*, to which the common eel belongs, the scarcely apparent scales are cycloid, narrow, oblong, arranged in groups at right angles to each other, forming a kind of lattice-work under the cuticle; the whole skin is soft and slimy, thickly studded with muciparous glands and ducts; the nostrils are double, each having two orifices, the anterior prolonged into a tube, and the posterior opening above the mouth; the teeth are card-like or villiform in both jaws, and a few on the anterior part of the vomer; the gill opening on each side is very small, and just in front of the pectoral fin, which exists in all the species; the dorsal fin begins at a considerable distance from the head, behind the pectorals, and forms a continuous fin with the caudal and anal; the lower jaw is longer than the upper. About 50 species are described. The common eel of the northern and middle states (*A. Bostoniensis*, Lesueur, and *vulgaris*, Mitch.) is greenish or olive-brown above, and yellowish or yellowish white be-

neath, often with a reddish tinge along the anal fin; in a specimen 2 ft. long, measured by Dr. Storer, the short pectorals were about 8 in. from the end of the snout. The eel inhabits both salt and fresh water, from the British provinces to the southern states, wherever it can find its favorite muddy bottoms and extensive flats; it prefers shallows near the shore, where it may be caught in great numbers by hook and line, by bobbing, and by spearing; the places frequented by it are called eel grounds, in which during winter the fishes bed themselves in the soft mud to the depth of about a foot, and are then speared through holes cut in the ice; the best time for catching them is at night, by torchlight. During their passage up and down rivers they are taken in baskets and pots baited with fish or any decaying matter. The eel is very voracious and quite omnivorous; when in good condition it is well flavored, though from its snake-like appearance (and it is only in form that it resembles a snake) most persons are prejudiced against it. The length varies from 6 in. to 2½ ft.; in summer it is sometimes seen weighing several pounds. At the mouths of the rivers emptying into Boston

Common Eel (*Anguilla vulgaris*).

harbor eels are caught in nets, 15 or 20 bushels at a time, and are kept alive until wanted in ditches supplied by the tide. The silver eel (*A. argentea*, Les.) is silvery gray, darker above, and satiny white below; the pectorals are nearer the head than in the common species, of which, however, it is considered by some only a variety; it is taken in pots in October, when it leaves the ponds. A large species, caught in the lakes of western New York, is the beaked eel (*A. rostrata*, Les.); the snout is elongated and pointed; the upper parts are olive-gray, sometimes slaty blue, and the lower parts white; the dorsal and anal fins reddish; length about 2 ft. The common eel of Europe (*A. acutirostris*, Yarrell) has a sharper snout than ours; it is highly esteemed as food, and the London market is supplied principally from Holland, from which the eels are brought alive in vessels carrying each from 15,000 to 20,000 lbs. Eels are much esteemed in other countries, especially, according to Ellis, in Polynesia, where they are often tamed and fed until they attain an enormous size. They are prolific, hardy, and easily preserved in salt, fresh, or brackish water. They make two migrations annually, one in autumn to the sea, the other in

spring or summer from the sea to the rivers. They are not found in arctic regions, nor in the rivers of the extreme north of Europe; even in temperate regions, at the approach of winter, they bury themselves in the mud, remaining torpid until spring; they remain without food, breathing hardly at all, at a low animal temperature, and almost motionless; yet the irritability of the muscular fibre is very great, as is shown by the restless motions of eels during thunderstorms, and by their well known movements after the skin has been removed. Though not possessing the respiratory pouches of the anabas, the eel is able to survive a long time out of water, simply because the gills remain moist from the small size of the branchial orifices; by this means it traverses considerable distances on land, moving like a snake through the grass; this explains the appearance of eels in fish ponds from which the utmost care has been taken to exclude them, on account of their destruction of the spawn and young of more valuable fishes; they have been often seen performing such overland journeys at night. Eels are found in fresh water which has no communication with the sea; having a capacious air bladder, they are able to ascend rapidly to the surface, and sometimes swim very high in deep water; though slow of growth, they attain a large size under favorable circumstances, having been caught in England weighing 27 lbs. The town of Ely is said to have been so named from the rents having been formerly paid in eels, the lords of the manor being annually entitled to more than 100,000; Elmore, on the Severn, was so called from the immense number of these fish there taken; so also Aalborg (Eel Town) in Denmark, &c.—The conger eels differ from the genus *anguilla* in having the dorsal fin begin nearer the head, at or even in front of the pectoral, and in having the upper jaw the longer; the anterior nostrils open by short tubes close to the end of the snout, and the posterior in front of the large eyes; the teeth of the palate and vomer are slender, with chisel-shaped crowns, and closely arranged; the skin is naked and scaleless, and the tail elongated and pointed; in other respects they resemble the common eel. The American conger (*conger occidentalis*, De Kay) is olive-brown

Conger Eel (*Conger occidentalis*).

above and whitish below; the dorsal and anal fins are transparent, with a dark border; the lateral line is distinct, with a series of white dots; it is from 3 to 5 ft. long, and either this or another species is found from the gulf of St. Lawrence southward as far as the coast of

New Jersey. The European conger (*C. vulgaris*, Cuv.) is common on the coast of Cornwall, on the eastern rocky shores, and in banks off the coast of France; it is caught on lines, the best bait being the sand lance (*ammodytes*) or the pilchard, and the fishing is performed at night; great numbers are taken, and meet with a ready sale at a low price to the poorer classes, but it is not held in much estimation. Congers are very voracious, and specimens have been caught weighing 130 lbs., more than 10 ft. long and 18 in. in circumference; they are very strong, bite sharply, and have great tenacity of life. As many as 156 vertebrae have been found in the conger, about 40 more than are found in the eel; they spawn in December and January. Sir John Richardson alludes to nine species.—The eel of the Mediterranean, so famous in the days of ancient Rome, belongs to the genus *muræna*, characterized by the absence of pectorals, smooth and scaleless skin, small lateral branchial orifice on each side, and the united dorsal and anal fins, low and fleshy, hardly distinguishable beyond the margin of the body; the teeth are arranged in a single row around the edge of the nasal bone, with a few on the longitudinal median line. More than 20 species are described, attaining the size of 4 or 5 ft.; one (*M. moringa*, Cuv.) was found by Catesby at the Bahama islands. The classic species of the Mediterranean (*M. Helena*, Linn.), the Roman *muræna*, grows to the length of 4 or 5 ft.; the color is a purplish brown, marked with sub-angular yellow markings, and spotted with beautiful shades of yellow, purple, golden yellow, and white; the anterior nostrils open near the end of the snout, the posterior just above the eyes; the cheeks are rather tumid from muscular development. It has been caught on the English coast, but it abounds in the Mediterranean; great numbers were consumed by the ancient Romans, who kept them in ponds, and placed them alive on the table in crystal vessels, that the guests might admire their beautiful colors before they were cooked. Cæsar is said to have distributed 6,000 of these fishes among his friends on the celebration of one of his triumphs. They are very voracious, fierce, and tenacious of life, and are said sometimes to have been fed on the flesh of slaves who had offended their Roman masters. Their bite is much dreaded by the fishermen. The flesh is white, delicate, and much esteemed. There are many species, exclusively marine.—The sand eel (*ammodytes Americanus*, De Kay) has an elongated, slightly compressed body, large gill openings, a dorsal fin extending nearly the whole length of the back, and an anal fin of considerable size, both separated from the caudal; the lower jaw the longer; the color is yellowish or bluish brown above, mixed with silvery and light green; the sides and abdomen are silvery; the length is from 6 to 12 in. This species is found from the coast of Labrador to that of New York; in the provinces it is largely used as

bait for cod; it is very common in Long Island sound from May to November, constituting in its season the principal food of the bluefish and bass; it is also eaten by eels and other fish; the cephalopod cuttle fish preys upon it extensively; like the tropical flying fish, it is pursued by fishes in the water, and by gulls and terns in the air. The names of sand lance and *ammodytes* are given it from its habit of darting out of and into the sand head foremost and instantly, by means of its projecting lower jaw. Its food is principally insects. On the coast of England it is esteemed as food, and is raked out of the sand at low tide in great numbers; it is also caught in seines. Two species are described.

EELS. See ILIYATS.

EESAH. See SOMAULI.

EFFERVESCENCE (Lat. *effervescere*, from *ex*, out of, and *fervescere*, to begin boiling), a state of ebullition, without vaporization, caused by the setting free of gases. It may be effected by chemical decomposition, or by diminishing the solvent capacity of a fluid which contains a gas in solution, either by raising its temperature, by diminishing the pressure upon it, or by adding some other body which in dissolving will cause a part of the gas to be expelled. Thus, when a solution of carbonate of soda is mixed with a solution of tartaric acid, the acid and soda unite and carbonic acid gas is set free, causing effervescence. If the solutions are very weak and very cold, the gas may be all absorbed by the water and no effervescence produced. At 65° F., and under the ordinary pressure of the atmosphere, water will absorb about its own volume of the gas. By lowering the temperature or increasing the pressure the amount of the gas absorbed will be increased. In the ordinary soda-water and mineral-water fountains the carbonic acid gas is held in solution under great pressure. When the water is drawn from the fountain into an open glass, the pressure being removed, the gas immediately begins to escape, causing effervescence. The gas is usually made by dissolving marble or chalk, which are carbonates of lime, in hydrochloric or sulphuric acid. It is then cleansed from impurities and forced by great pressure into a condenser, whence it is transferred to the fountains. Effervescence may also be caused by dissolving zinc in dilute sulphuric acid, or zinc or iron in hydrochloric acid. In both cases hydrogen gas is set free. —**EFFERVESCING POWDERS** are preparations of acid and alkaline powders, put up in differently colored papers in order to distinguish them. They are administered by first dissolving the contents of two different papers in separate glasses, then mixing the solutions, and drinking while the chemical reaction is taking place with effervescence. The common soda and Seidlitz powders form effervescing draughts, the acid in one of the papers combining with

the alkali of the carbonate in the other, and expelling the carbonic acid. This gas, continuing to be evolved in the stomach, acts as a refrigerant and diaphoretic, while the alkaline salt is slightly laxative. The drink is especially adapted to febrile complaints. The common soda powders consist of 25 grains of tartaric acid in one paper, and 30 grains of bicarbonate of soda in the other. An equivalent proportion of bicarbonate of potash is sometimes substituted for the soda. The following are the proportions given in the "American Dispensatory": tartaric acid 1 oz., bicarbonate of soda 1 oz. and 54 grains, or bicarbonate of potassa 1 oz. and 160 grains. The acid and either bicarbonate, being separately reduced to fine powder, are divided each into 16 portions. Citric acid is sometimes employed instead of the tartaric acid, in the proportion of 9 drachms to 11 of the soda salt, or 13 of the potash. Seidlitz powders are a mixture of 2 drachms of Rochelle salts (tartrate of potash and soda) and 2 scruples of bicarbonate of soda in one paper, and 35 grains of tartaric acid in the other. The tartaric acid being in excess renders the medicine more pleasant to take, without interfering with its aperient quality. The acid and the carbonate may be prepared in a single powder, in which the chemical action does not take place until it is dissolved in water. Such a preparation should of course be carefully preserved from moisture. Seidlitz and Rochelle powders are more laxative than the common soda powders.

EFFINGHAM. I. An E. county of Georgia, separated on the east from South Carolina by the Savannah river, and bounded W. by the Ogeechee; area, 480 sq. m.; pop. in 1870, 4,214, of whom 1,704 were colored. The Georgia Central railroad passes through it. The surface is level, and the soil sandy. Pine and cypress are found. The chief productions in 1870 were 55,854 bushels of Indian corn, 15,932 of sweet potatoes, 294 bales of cotton, and 149,455 lbs. of rice. There were 294 horses, 283 mules and asses, 2,201 milch cows, 4,510 other cattle, 1,238 sheep, and 8,162 swine. Capital, Springfield. **II.** A S. E. county of Illinois, drained by Little Wabash river; area, 500 sq. m.; pop. in 1870, 15,653. The surface is level and partly wooded, and the soil fertile. Copper, iron, and lead are found. The Chicago division of the Illinois Central, and the St. Louis, Vandalia, Terre Haute, and Indianapolis railroads pass through it. The chief productions in 1870 were 195,793 bushels of wheat, 19,759 of rye, 620,247 of Indian corn, 386,073 of oats, 54,671 of potatoes, 11,360 tons of hay, 210,155 lbs. of butter, and 35,650 of wool. There were 4,907 horses, 4,316 milch cows, 5,893 other cattle, 13,228 sheep, and 17,259 swine; 8 flour mills, 12 saw mills, 5 manufactories of saddlery, and 2 of woollen goods. Capital, Effingham.

EFT, a name given to several species of newts, especially to the common smooth newt

(*Lissotriton punctatus*, Dand.). The generic characters of the tritons, or aquatic salamanders, will be given under TRITON, which the eft resembles in the slightly free tongue, double longitudinal series of palatal teeth, and nailless toes, four before and five behind. The skin is smooth, and the dorsal and caudal crests are continuous; there are two patches of glandular pores on the head, and none on the back or sides. The newts belong to the genus *molge* of Merrem, and *triton* of Laurenti. Bell separated the efts in the genus *lissotriton*. The color in the male is brownish gray above, passing into yellowish beneath, which in the spring becomes bright orange; there are numerous round dark spots of unequal size, and two longitudinal streaks on the head; the crest in spring is often tipped with red or violet. The female is light yellowish brown, or buff with brown dots, plainer below. The total length is about $3\frac{1}{2}$ in., of which the tail is nearly one half. It is very common in the ditches and ponds of Europe, especially where the water is clear; its food consists

Eft (*Lissotriton punctatus*).

principally of aquatic insects, larvæ, worms, and mollusks. The reproduction and metamorphosis are almost identical with those of the newts. Though usually spending most of their time in the water, the young in June, and the adults in summer and autumn, become terrestrial; they appear to attain their full size the first year. The experiments of Spallanzani show that the members of the tail may be reproduced several times in succession, with bones, muscles, vessels, and nerves. Like the other amphibia, it is very tenacious of life, and can resist even congelation. Its bite is perfectly harmless.

ÉGALITÉ, Philippe. See ORLEANS.

EGBERT, king of Wessex, and first king of the united Anglo-Saxons, born about 775, ascended the throne of Wessex in 800, and died about 836. The defeated rival of King Brihtric, he took refuge first at the court of Offa, king of Mercia, and afterward in France, where he was received at the court of Charlemagne, in whose armies he served three years. After the death of Brihtric in 800 he was the last

remaining prince of the house of Cerdic, and was recalled and acknowledged as king by the West Saxon thanes. In 809 he commenced his career of conquest; and, successively subduing the Britons of Cornwall and the Saxons of Mercia, Kent, Essex, and Northumbria, and assuming at its request the protectorship of East Anglia, by 827 he had become the actual sovereign of the whole heptarchy, and in 828 assumed the title of king of England. In 832 the Danes landed on the isle of Sheppey, and carried off a rich booty. In 833 they disembarked at Charnmouth, and defeated Egbert's forces. They landed again in 835 on the coast of Cornwall, where they formed an alliance with the Britons. Egbert encountered their united forces at Hengston hill, gained a decisive victory, punished the rebels, and drove the invaders to their ships.

EGEDE. I. Hans, the apostle of Greenland, born in Norway, Jan. 31, 1686, died in November, 1758. After having been several years a pastor near Dröntheim, he resigned in 1717, to embark for Greenland as a missionary. The wars with Charles XII. of Sweden engrossing the public attention, he was unable immediately to execute his design; but he received the patronage of Frederick IV. of Denmark in 1719, set sail in May, 1721, with his wife, two sons, and some 40 other persons, and in July following landed on the coast of Greenland in lat. 64° N. His mildness and zeal gained the affections of the rude natives, and after several years of effort he was able to preach the gospel in their language. Various calamities, among which were the ravages of the smallpox, almost annihilated the result of his labors; yet before his departure he succeeded in laying a foundation for the propagation of Christianity and for an important commerce. The Danish government sent out three Moravian Brethren to aid him, and after a residence of 15 years in Greenland, Egede, seeing the colony flourishing, returned to Denmark. He published several works on Greenland, and superintended a seminary for the education of missionaries. **II. Paul**, son of the preceding, born at Waagen, near Dröntheim, in 1708, died June 3, 1762. He returned from Greenland in 1728, bringing several Esquimaux, but they all died of the smallpox. After studying theology he went back to the mission, and labored there four years after the return of his father. He translated the "Imitation of Christ" and portions of the Bible into the language of Greenland, and at his departure left the colony highly prosperous. He fulfilled various functions in Denmark, was active in expediting the exploring mission of Löwenön to the coast of Greenland, and at the time of his death occupied a chair of theology.

EGER (Boh. *Cheb*), a frontier city of Bohemia, on a river of the same name, at the foot of the Fichtelgebirge, and at the junction of six lines of railway, 91 m. W. of Prague; pop.

in 1869, 13,463. It has cotton and woollen manufactories, and in its vicinity at Franzensbad are chalybeate springs and baths. Its fortifications, formerly strong, were demolished in 1808. It has a city hall, in which Wallenstein was assassinated, Feb. 25, 1634, the ruins of a castle in which the friends of Wallenstein were murdered, a gymnasium, military school, chamber of commerce, two convents, and four churches.—Eger was formerly the capital of a county of that name, and belonged to the margrave of Vohburg, and passed over by marriage to the emperor Frederick I. In 1270 the city was burned down, and in 1285 the emperor Rudolph gave it as a marriage portion to King Wenceslas of Bohemia. In 1350 a great massacre of the Jews took place here. It was taken and retaken by both Swedes and imperialists during the thirty years' war. In the Silesian wars it was taken by the French under Marshal Saxe in 1742, and again under the marshal de Belleisle in 1745. (For Eger in Hungary, see ERLAU.)

EGERIA, one of the Camenæ or nymphs of Roman mythology, who was believed to have dictated to Numa Pompilius his wise laws, and to have instructed him respecting the forms of worship which he introduced. It was said that she became his wife, and that being inconsolable after his death, she was changed into a fountain. She had been worshipped as a rural and prophetic divinity from the earliest periods of Latium, and was invoked as the giver of life by pregnant women. Numa consecrated to her a grove in the environs of Rome, and to strangers visiting that city even now the grotto and fountain of Egeria are pointed out in the beautiful valley of Caffarella. On ancient sculptures this nymph is represented in a costume similar to that of the muses, with floating robe, naked feet, dishevelled hair, and in the attitude of writing in a volume which she holds upon her knees.

EGERTON, Francis. See BRIDGEWATER.

EGERTON, Thomas, baron of Ellesmere and Viscount Brackley, lord chancellor of England, born at Dobbleson, Cheshire, in 1540, died in London, March 15, 1617. He was educated at Brasenose college, Oxford, was called to the bar, and by his learning and integrity soon attracted the attention of Queen Elizabeth. He was appointed successively solicitor general, attorney general, master of the rolls, and in 1596 lord keeper. James I., on his accession, created him Baron Ellesmere, and appointed him lord high chancellor. He was subsequently elected chancellor of the university of Oxford. In 1616 he was made Viscount Brackley. A few days before his death he resigned the great seal, having retained it, as lord keeper and chancellor, for a longer period uninterruptedly than any of his predecessors or successors. He was succeeded by Sir Francis Bacon. Besides his judicial duties, he was frequently employed by Elizabeth and James in the negotiation of treaties, and in other im-

portant state affairs. His son John was the first earl of Bridgewater (1617), and lord president of Wales.

EGG, the organized germinal body from which all animals originate, formed within the mother, and developed into the living being either before or after extrusion. In this article only those of the latter kind, chiefly of birds, will be considered; the general subject will be treated under EMBRYOLOGY. The eggs of many of the lower orders of animals are collected and held together in great numbers by a viscous membrane, and are called spawn. Those of birds and of many reptiles, as the tortoises and turtles, are deposited singly. Birds' eggs are contained in a calcareous shell, white or colored, formed almost wholly of carbonate of lime; the other constituents are minute quantities of animal matter, phosphate of lime, carbonate of magnesia, oxide of iron, and sulphur. Lining this hollow shell is a thin and tough membrane, composed principally of albumen. At the larger end of the egg is a space between the outer shell and this membrane, which, very small when the egg is first laid, increases with its age; it is called the *vesicula æris*, and is filled with air, in which the proportion of oxygen is larger than in the atmosphere; this is said to be for the respiration of the unhatched chick. Within the membrane is the white of the egg, or the albumen, a viscid liquid, in membranous cells, which encloses the yolk and the real germ of the animal. As this germ leaves the place of its production and passes into the egg-discharging canal, the albumen gathers around it in successive layers, a portion in very delicate membranes, called the *chalazæ*, which are attached to the poles of the yolk, and serve to suspend it in such a manner that the smaller and lighter half must always be uppermost. The outer layer of the albumen is less thick and viscid than that next the yolk; around it the lining membrane and calcareous shell are successively added before the egg is laid. In the hen's egg, the composition of the albumen is: water 85 parts, pure albumen 12, mucus 2·7, and saline matter 0·3, including soda with traces of sulphur; or, according to Dr. Thomson, water 80, albumen 15·5, mucus 4·5, ash 0·475. The yolk, called *vitellus*, is also a glairy fluid, commonly yellow, enclosed in its own membrane, and consists of a great variety of constituents, viz.: water, 41·486; a form of albumen called vitelline, 15·76; margarine and oleine, 21·304; cholesterine, 0·438; oleic and margaric acids, 7·226; phosphoglyceric acid, 1·2; muriate of ammonia, 0·034; chlorides of sodium and potassium and sulphate of potassa, 0·277; phosphates of lime and magnesia, 1·022; animal extracts, 0·4; and 0·553 of coloring matter, traces of iron, lactic acid, &c. Upon one side of the yolk is a round spot, yellowish white, called the *cicatricula*, the germ of the ovum, which by the arrangement of the *chalazæ* already referred to is always kept

uppermost, and next to the source of heat supplied by the animal in sitting. As this is developed into the fetus, the albumen first furnishes nourishment to it, and when this is consumed more is supplied by the yolk. Eggs of the hen are hatched by being kept at a temperature of 104° for three weeks. Their vitality has been retained after they have been exposed to a temperature of 10° F.; and it is a remarkable fact that the freezing point of new-laid eggs is much lower than that of the water and albumen of which they principally consist, both of which congeal at about the same temperature. Eggs that have been once frozen, or have been long kept, freeze at the point their constituents would require. The specific gravity of new-laid eggs is from 1.08 to 1.09; by keeping they diminish in weight from evaporation of water, and the substitution of air through the pores of the shell. This diminution has been observed to continue for two years; an egg weighing originally 907.5 grains being reduced, as remarked by Dr. Thomson, to 363.2 grains. When they have lost so much weight as to float upon water, they are generally unsound. The preventing of this evaporation by covering their surface with a coating of varnish, wax, gum arabic, or lard, checks their putrefaction. The Scotch sometimes drop them into boiling water for two minutes, by which the membrane within the shell is partially coagulated and rendered impervious to air. Hens' eggs vary so much in gravity, that it is a wonder they continue to be sold by numbers instead of weight. A dozen of the largest have been found to weigh 24 oz., while the same number of smaller ones of the same stock weighed only $14\frac{1}{2}$ oz. The fair average weight is about $22\frac{1}{2}$ oz. to the dozen. The relative weights of the portions of the egg as given by Dr. Thomson are: shell and membrane, 106.9; albumen, 604.2; yolk, 288.9. About one third of the entire weight may be regarded as nitrogenous and nutritious matter; a greater proportion than that of meat, which is rated at only from 25 to 28 per cent., while the nutritive portion of the oyster is only about 12 per cent. The white of the egg, from its tendency to coagulate into a hard and indigestible substance, is likely to disagree with the stomach of invalids, when the yolk may prove perfectly harmless. Raw eggs are more wholesome than boiled, or even than those lightly poached, which are very digestible. Eggs become more difficult of digestion by being kept.—In medicine the shell is used as an antacid, its animal composition seeming to adapt it better for the stomach than chalk, the mineral form of carbonate of lime. The white is employed for clarifying liquors and sirups, which it accomplishes by entangling the small particles floating in them as it coagulates, and either rising with them to the surface, or sinking to the bottom. An astringent poultice is formed by causing it to coagulate with a piece of alum briskly stirred with it. This, under the name

of alum curd, is used as an application to the eye in some forms of ophthalmia. The white is also used as an antidote to corrosive sublimate and salts of copper. The yolk is sometimes given in jaundice, and forms an excellent diet in dyspepsia; it is preferable to the white in making emulsions.—The largest eggs of which we have any account are some found in 1850 in alluvium in Madagascar. They belong to a bird which it is supposed has recently become extinct, to which M. Saint-Hilaire has given the name of *epiornis maximus*. Two of the eggs are preserved in the French academy, and casts are to be seen in the principal museums of the world. One of them measures $13\frac{1}{2}$ in. on its longest diameter, and $8\frac{1}{2}$ in. on the shortest. The shell is about one eighth of an inch thick. The capacity of the egg is about $8\frac{1}{2}$ quarts, six times that of the ostrich's egg, and equal to 144 hens' eggs, or 50,000 eggs of the humming bird. From some of the bones of the bird which have been preserved, its height is calculated to have been about 12 ft.

EGG, Augustus Leopold, an English painter, born in London, May 2, 1816, died in Algiers, March 26, 1863. He became a contributor to the academy exhibition in 1838, and was elected associate of that institution in 1848, and a member in 1860. He produced a great number of pictures illustrative of humorous scenes from Shakspeare, Le Sage, and Scott.

EGG PLANT, or Vegetable Egg, the popular name of a species of the *solanaceæ* (*solanum melongena*, Willd.), a native of North Africa. The plant grows to the height of about two feet, with a prickly stem, and with large ovate, downy, prickly leaves; flowers of a violet

Egg Plant (*Solanum melongena*).

color, of some beauty; fruit, a globose berry, crowding itself out from the downy calyx, which remains until the fruit ripens, and the deep purple color it assumes indicates its perfection. Its size depends considerably upon richness of soil and warmth of climate; in

propitious seasons it reaches several pounds' weight. It is a favorite article of food in India and other hot countries, and is much used in the United States. It is generally served up in India with sugar and wine, and is used by the French and Italians in stews and soups. Another smaller species is *S. ovigerum*, having a white fruit of the size and appearance of a fowl's egg, chiefly cultivated as an ornamental curiosity, and sometimes reared in pots to secure the ripening, as a long season seems requisite at the north. The seeds of the egg plant should be sown on a slight hot-bed in March or early in April, and the plants should be transplanted in the latter part of May, or in June, in rich, warm ground, 2½ ft. apart every way. The soil should be frequently loosened with the hoe, and drawn up around the stems. Among the Chinese, *S. Ethiopicum*, having similar fruit, furnishes an ornamental dish on great occasions.

EGINHARD, or **Einhard**, the secretary, confidential adviser, and biographer of Charlemagne, born in Austrasia, died at Seligenstadt about 844. He was a pupil of Alcuin, who introduced him at court. He retired after his patron's death to a country residence near Mühlheim, in the Odenwald, where he devoted himself to literary pursuits. After the death of his wife, who according to a romantic tradition was a daughter of Charlemagne, he built a convent at Seligenstadt, in the present grand duchy of Hesse, and entered it as a monk. The sarcophagus, in which he and his wife were buried is still shown at the castle of Erbach, and the counts of Erbach claim to be his lineal descendants. The *Vita Caroli Magni*, by Eginhard, is one of the best biographical works of the middle ages. It has been republished by Ideler (Hamburg, 1839), and also in the second volume of Pertz's *Monumenta Germaniæ Historica*. Eginhard's *Annales Regum Francorum*, and a collection of his letters, are likewise of value to the historian.

EGLANTINE, an old English name for the sweet brier (*rosa rubiginosa*, Linn.), which grows plentifully in rich pastures and neglected fields. In deep soils and under favorable circumstances it is not uncommon for the old roots to send up vigorous shoots or suckers 8 or 10 ft. high, which are covered with harsh, crooked prickles. The flowers, which are for the most part borne upon the lower branches, are of a beautiful light rosy color, and full of fragrance. But the chief perfume of the plant is in the foliage, its leaves being beset with russet-colored glands, which on being slightly bruised emit a peculiar scent. The eglantine succeeds well in the garden, if ample room and a deep soil are allowed it, and in such cases it has been known to produce occasionally double flowers. It grows readily from the seeds, and sown in rows the plants have been clipped into shape to form low and ornamental hedge divisions. The species best known in the United States is supposed to be an adventitious one

from Europe, and was introduced with a co-species, also fragrant (*R. micrantha*, Smith), having smaller flowers and a different-shaped

Eglantine (*Rosa rubiginosa*).

fruit or seed vessel. Both have extended scarcely beyond the seacoast of New England.

EGMONT, or **Egmond**, **Lamoral**, count of, a soldier and statesman of the Netherlands, born in the castle of La Hamaide, Hainaut, in 1522, beheaded in Brussels, June 5, 1568. He inherited from his mother the title of prince of Gavre and from his father that of count of Egmont, and preferred to be known by the latter. While a boy he was a page at the court of the emperor Charles V. In his 19th year he commanded a troop of horse in the expedition against Algiers. In 1545 he married Sabina of Bavaria, sister of the elector palatine. The next year he was invested with the order of the golden fleece. In 1554 he was placed at the head of the embassy sent to England to solicit the hand of Queen Mary for Philip II. of Spain. He commanded the cavalry of the Spanish army in 1557 on the invasion of France. St. Quentin having been invested, Egmont made a brilliant charge upon the French, who came up to its relief under Montmorency, and defeated them. In 1558 the French under Marshal de Thermes invaded West Flanders, and laid waste the country. Egmont intercepted them at Gravelines on their march homeward with their booty, cut their army in pieces, and took the marshal prisoner. These victories added greatly to his reputation, and he was appointed by Philip II. stadtholder of Flanders and Artois. In this position he favored somewhat the party who were dissatisfied with the king's administration, being swayed alternately by sympathy with the popular movement and by his loyalty to the throne and devotion to the Roman Catholic church. When Margaret of Parma was appointed regent of the Netherlands in 1559,

with Granvelle as minister, Egmont and the prince of Orange were made members of the state council. Important affairs of state having been transacted by the regent and Granvelle without consultation with the council, Egmont in 1561 and 1563 joined in letters of remonstrance to the king. His opposition to Granvelle finally forced him to give up his position and leave the country. In 1565 he was sent as envoy to the court of Spain for the purpose of making the condition of the Netherlands better understood. The king made him many promises, but the government did not relent in its severity toward the provinces. On the contrary, nine inquisitors were sent thither to reestablish the inquisition. Egmont was indignant, and permitted the assembling of the nobles (1566), who declared that they would never submit to the inquisition and founded the league of the Gueux. During the iconoclastic risings which broke out soon after, Egmont obtained from the regent favorable terms for the insurgents who belonged in the provinces over which he was stadtholder. These terms having been ratified by the king, Egmont's confidence in the royal favor was strengthened. He restored the Catholics to the possession of their churches, and restrained and punished the excesses of the Protestants. He aided the royal troops in besieging Valenciennes, renewed his oath of allegiance to the regent, and finally broke off his connection with the prince of Orange and the Gueux. When Philip II. in 1567 sent the duke of Alba with a strong army to take the place of Margaret of Parma, the prince of Orange and other leaders of the people left the country; but Egmont, relying upon his interest at court, remained to look after his estates. He went out to meet the duke of Alba as he approached Brussels, and made him a present; but he was treacherously arrested, Sept. 9, together with the count of Horn. They were tried by the "council of blood," and adjudged guilty of treason. Egmont met his death with calmness, and was regarded by the people as a martyr in the cause of liberty.—One of Goethe's tragedies is founded upon his history. See Prescott's "History of Philip II.;" *Le comte d'Egmont et le comte de Horne*, by Juste (Brussels, 1862); and Motley's "Rise of the Dutch Republic."

EGRET, a name given to those species of white herons which have the feathers of the lower part of the back elongated and their webs disunited, reaching beyond or to the tail, at certain seasons; their forms are also more graceful than those of common herons. They belong to the old genus *ardea* (Linn.), of the order *grallatores*, since divided into many subgenera. The great American egret (*A. [herodias] egretta*, Gmel.) is about 37 in. long to end of tail, 49 to end of claws, with an extent of wings of 55 in.; bill $4\frac{1}{2}$ in., tail $6\frac{1}{4}$, tarsus 6; anterior toes $2\frac{3}{4}$, 4, and $3\frac{1}{8}$ in., with the claws, $\frac{3}{8}$, $\frac{3}{8}$, and $\frac{3}{8}$ of an inch respectively; the hind toe $1\frac{1}{2}$, and its claw $1\frac{1}{8}$ in. long; weight about

21 lbs.; the female is somewhat smaller. The bill is straight, tapering to an acute tip; the head compressed and oblong; neck long and slender; body compressed; feet, tarsus, and tibia long, the latter bare in its lower half. The space between bill and eye, and around the latter, is bare; the plumage is soft and blended; head not crested, though its feathers are elongated, as are those on the lower neck in front; from between the shoulders arises a tuft of long, decurved, and delicate disunited feathers, extending about 10 in. beyond the tail; the wings are moderate, and the tail short, of 12 weak feathers; the bill is bright yellow, feet and claws black, and the plumage white, in some parts slightly tinged with yellow. This elegant bird breeds from Florida to New York, and along the shores of the gulf of Mexico to Texas, and probably further; it is rarely seen in Massachusetts, and does not appear more than 50 miles inland, unless along the courses of large rivers; it generally breeds in

Great American Egret (*Ardea egretta*).

low marshy places, dismal swamps, and the margins of lakes and ponds; the nests are sometimes made on low bushes, and occasionally on sandy islands near the coast, but generally on high trees. The long, silky filaments of the back are hardly to be seen except in the love season, which varies from early spring to midsummer, according to latitude; both sexes possess them, and many are shot during the breeding season to obtain these feathers for ornamental purposes. It feeds by day, on small fishes, crustacea, and reptiles, which it catches in the shallows and marshes; its flight is well sustained, and its gait and movements are graceful. The nest is made of loose sticks, overhanging the water, and is used for years by the same birds, which annually repair it; the eggs, two or three in number, are $2\frac{1}{4}$ in. long, when freshly laid smooth and pale blue, becoming afterward rough and whitish. The egret is shy and difficult to obtain, except in the breeding season; many of the young are destroyed by crows and turkey buzzards.—The European egret (*A. alba*, Gmel.) is about 3 ft. 5 in. long, with pure white plumage. Accord-

ing to Selby, the bill is black or dark brown, yellow at the base and about the nostrils, and the legs are almost black. It is common in southern Europe, but comparatively rare in the northern and central parts; the white herons of Asia are believed to be of this species. The

Great White Egret (*Ardea alba*), and Little Egret (*A. garzetta*).

little European egret (*A. garzetta*, Linn.) is about 22 in. long from bill to end of tail; the plumage is white; from the hind head spring two narrow feathers 4 in. long; the plumes of the back are elongated; the bill and tarsi are black; the tarsus is 4 in. long. This species is

Reddish Egret (*Ardea rufa*).

confined to the eastern hemisphere, being most abundant in southern Europe, Greece, and northern Africa; it occasionally wanders as far as England. The buff-backed egret (*A. Coromanda*, Bodd.) is about 20 in. long, the bill 2 in. and orange yellow; the plumage is white,

except the top of the head and front neck, which are buff, becoming browner as the bird grows older; it is very generally distributed over Asia. The reddish egret (*A. [demi-egretta] rufa*, Bodd.), of which Peale's egret is believed to be the young, is about 31 in. long, and 46 in extent of wings; the pale bill has a black tip; the iris is white; the feathers of the head and neck are loose and pendent, of a light reddish brown tinged with lilac, fading into brownish white at the tips; the back and wings grayish blue; long feathers of the back yellowish-tipped; pale grayish blue below. It seems never to go far from the Florida keys, except westward along the gulf of Mexico; it is a plump and graceful bird, and an easy and high flier; it rarely associates with other species; it is probably strictly marine. The nests are made by the middle of April; the eggs are three, of a pale sea-green, and are excellent food.

EGYPT (Gr. Αἴγυπτος; Lat. *Ægyptus*; Heb. *Mitzraim*; Coptic, *Khami* or *Kemi*), a dependency of the Turkish empire in N. E. Africa, bounded N. by the Mediterranean, and E. by the Red sea and a direct line from Suez to El-Arish, a seaport town on the Mediterranean. Egypt proper extends S. to the first cataract of the Nile, between Asswan and Philæ, lat. 24° 5' N., and W. beyond the oases of the Libyan desert to the frontier of Barca. The area is estimated in an annual publication of the Egyptian government, *Le guide général d'Égypte* (Alexandria, 1870), at 216,000 sq. m. But the rule of the viceroy has of late also been established over an extensive region to the south, officially called Soudan, which comprises Lower Nubia, Sennaar, Dongola, Taka, Fazoglu, Kordofan, the provinces of the White Nile, and Khartoom, and since 1865 also the coasts of the Red sea down to and inclusive of the seaport town of Massowah, lat. 15° 34' N. Inclusive of this territory, the area of the Egyptian empire was in 1872 estimated by Régny at 730,000 sq. m. Egyptian rule was recently extended by Sir Samuel Baker over a vast territory reaching south to the equator.

—With the exception of a few small rivers that empty into the Red sea, the Nile is the main irrigator of the country. The White and Blue Nile unite near the city of Khartoom, forming the Nile proper, which assumes a winding N. E. course through Nubia, and receives near El-Damer the Atbara, coming from the south-east. It flows thence in a N. N. W. direction till it reaches El-Gooba, where it turns abruptly S. W., enclosing the northern point of the Bayuda desert. At Ambukol it resumes its N. N. W. course, descends the cataract near Haffir, turns N. N. E., and enters Egypt proper at the island of Philæ near Asswan, the ancient Syene, where it descends the famous cataracts, and flows thence unbroken by falls or rapids, and not augmented even by a rivulet, till it reaches the Mediterranean. From the cataracts the river, whose general breadth is about half a mile, runs for 600 m. through a valley

bounded by hills varying in height from 300 to 1,200 ft. The average breadth of the valley is 7 or 8 m., its greatest breadth 11 m. Anciently the whole of this valley was called Upper Egypt, but afterward the term Middle Egypt was applied to the northern part of it. About 100 m. from the sea the hills disappear, and the river enters an extensive and perfectly level alluvial plain, where, 12 m. N. of Cairo, it separates into two great streams, which continually diverge until they reach the Mediterranean by mouths about 80 m. apart, the eastern at Damietta and the western at Rosetta. This great plain is Lower Egypt. The triangular space enclosed by the two arms of the river and the sea is called the Delta, from its resemblance in shape to the Greek letter Δ ; but the term Delta is also sometimes applied to the whole plain, or to so much of it as consists of fertile land. The greater part of the country consists of deserts, with the exception of the valley of the Nile, a few oases, and the region called Fayoom, which lies at no great distance W. of the Nile, between lat. 29° and 30° , and has a fertile area of 340 sq. m. The largest of the oases, the one most remote from the Nile, is Siwah, the ancient Ammonium, the site of the temple and oracle of Jupiter Ammon. It lies ten days' journey W. of Fayoom, and has an area of only 15 or 20 sq. m. The desert between the Nile and the Red sea is intersected by chains of mountains, whose highest summits attain an elevation of 6,000 ft.—The most noted lake of Egypt is the Birket el-Keroon, in the N. W. part of Fayoom; it is 30 m. long and from $2\frac{1}{2}$ to $3\frac{1}{2}$ m. broad. The remains of the famous ancient artificial lake Moeris have been identified in the E. part of Fayoom. To the north of the Birket el-Keroon, at the distance of 50 m., are the natron lakes, from which the water evaporates in the dry season, leaving the ground covered with a crust of natron or carbonate of soda. Along the seacoast of the Delta is a series of lagoons stretching for nearly 200 m., of which the principal are Lake Maryoot, the ancient Mareotis, 40 m. long, Lake Boorlos, 30 m. long, and Lake Menzaleh, 50 m. long, with an average breadth of 15 m. From a very ancient period Egypt has abounded in canals, chiefly constructed to facilitate the distribution of the water of the Nile for irrigation. The Mahmoudieh canal, 50 m. long and 100 ft. broad, was made in 1820 to accommodate the commerce between Alexandria and the Nile. Great efforts have been made during the last 20 years to render the country less dependent upon the annual inundation. The Mahmoudieh canal was connected with about 50 new canals for irrigation, which proved of some service in 1868, when the Nile failed to attain its usual height. The canal across the isthmus of Suez, to unite the Red sea with the Mediterranean, was begun in April, 1859, and opened in November, 1869. (See CANAL.)—The most striking geological feature of Egypt is the vast bed of alluvium deposited by the Nile, which covers all

Lower Egypt to a depth that probably averages 30 or 40 ft. The predominant rocks are limestone, sandstone, and granite. The great pyramids are built of limestone, and stand on a limestone plateau. This rock extends up the valley of the Nile as far as Esne, and thence to Asswan or Syene sandstone prevails, from the quarries of which most of the temples of Egypt have been built. At Asswan, at the southern extremity of the country, granite predominates, and the quarries there have chiefly furnished the materials for the obelisks and colossal statues of Egypt. The soil is of unsurpassed fertility, and its richness is annually renewed by the inundation of the Nile, which deposits upon the land a coating of mud rendering needless any other manure. In many parts ploughing is dispensed with, the seed being thrown upon the mud, and sheep, goats, or oxen turned loose in the fields to trample in the grain; though in other parts agriculture is carried on with considerable labor and care, especially where artificial irrigation can be resorted to. The rise of the Nile begins in Egypt in the latter part of June; but it is perceptible at Gondokoro, lat. 5° N., as early as February, at Khartoom in the latter part of March, and at Dongola in May. The inundation reaches its greatest height between Sept. 20 and 30, when it is usually 24 ft. above the low-water level. It remains at that height about 15 days, and then gradually falls, till it is at the lowest about the middle of May. It rises sometimes 30 ft., when it does great damage. If it rises less than 18 ft., a famine is the consequence in some districts not yet under artificial irrigation. The following plants are sown immediately after the inundation begins to subside, and are harvested three or four months later: wheat, barley, beans, peas, lentils, vetches, lupins, clover, flax, lettuce, hemp, coriander, poppies, tobacco, watermelons, and cucumbers. The following are raised in summer chiefly by artificial irrigation: durra, maize, onions, henna, sugar cane, cotton, coffee, indigo, and madder. Grapes are plentiful, and other fruits abound, of which the most common are dates, figs, pomegranates, apricots, peaches, oranges, lemons, citrons, bananas, mulberries, and olives. There are no forests in Egypt, and few trees of any kind except the palm, of which there are usually groves around the villages. From the absence of forests there are few wild beasts, the principal species being the wolf, fox, jackal, hyæna, wild ass, and several kinds of antelope. The chief domestic animals are camels, horses, asses, horned cattle, and sheep. The hippopotamus is no longer found in Egypt, though it is met with in the Nile above the cataracts, and the crocodile has abandoned the lower part of the river, and is becoming rare even in Upper Egypt. Among the birds are three species of vultures (one of which sometimes measures 15 ft. across the wings), eagles, falcons, hawks, buzzards, kites, crows, linnets, larks, sparrows, and the beautiful hoopoe, which is regarded with

superstitious reverence. Pigeons and various kinds of poultry are very abundant. The ostrich is found in the deserts. Among the reptiles are the cerastes and asp (*naya haye*), both deadly poisonous. Fishes abound in the Nile and in the lakes, and furnish a common and favorite article of food. Locusts occasionally invade the country and commit great ravages.—The climate of Upper Egypt differs from that of Lower Egypt, which has occasionally considerable rain, while the former is an almost totally rainless district. The average temperature of Lower Egypt ranges between 80° and 90° in summer and 50° and 60° in winter, and that of Upper Egypt between 90° and 100° in summer and 60° and 70° in winter. The most common diseases are dysentery, liver complaints, and ophthalmia, the last being very prevalent. The plague was formerly frequent and virulent, but owing to the sanitary precautions of the government it has not made its appearance since 1843. One of the most disagreeable features of the climate is the kham-sin, a hot wind from the desert which prevails for 50 days, beginning generally about May 2, and has a peculiarly oppressive and unhealthy effect.—In 1871 the country was divided into 13 provinces, 7 of which belong to Lower Egypt and 6 to Upper Egypt, Middle Egypt being at present only a geographical abstraction. The provinces of Lower Egypt E. of the Nile are: Kaliubieh, capital Kalioob; Sharkieh, capital Zagazig; Dakalieh, capital Mansoorah; in the Delta: Menoofieh, capital Menoof; Garbieh, capital Tanta; W. of the Nile: Behareh, capital Damanoor; Gizeh, capital Gizeh. The provinces of Upper Egypt, or Said, are Beni-Sooef, Minieh, Sioot, Girgeh, Kenneh, and Esne; they are named after their capital cities, with the exception of Girgeh, of which Sohag is the capital. To these has recently been added the province of the Isthmus, capital Ismailia. The cities of Cairo, Alexandria, Suez, Port Said, Damietta, Rosetta, and Kosseir are exempt from the provincial administration and placed under governors of their own. Special governors were also appointed in 1865 at Massowah and Sooakin on the Red sea, who are dependent on the governor general of the southern provinces (residing in Khartoom), but are authorized to report directly to Cairo all important matters concerning the Red sea. Subordinate to the governor of a province (*mudir*) are the heads of districts (*kosufs*) and cantons (*nasirs*); the heads of single localities bear the title *sheikh el-beled*, which is also that of the magistrates of the wards of larger cities. Anciently, under its native rulers and their Persian, Greek, and Roman successors, the country was divided into districts called nomes, varying in number at different eras from 36 to 56 or 58.—A government census in 1866 officially stated the number of inhabitants at 4,848,529. In March, 1871, the population of Egypt proper amounted, according to Régnv, to 5,115,367 natives and 88,038 foreigners; total, 5,203,405;

the foreign population consisting of 34,000 Greeks, 24,000 Italians, 17,000 Frenchmen, 6,500 Austrians and Germans, and 6,000 Englishmen. With the exception of 600,000 Christians, namely, 350,000 Copts and 250,000 Franks, the inhabitants are all Mohammedans. They call themselves Arabs, though they are probably in great part descended from the ancient Egyptians. They are handsome, well made, and courteous. In northern Egypt they are of a yellowish complexion, growing darker toward the south, until the hue becomes a deep bronze. Mr. Lane speaks highly of their mental capacity, and gives them credit for uncommon quickness of apprehension and readiness of wit. They are highly religious, and are generally honest, cheerful, humane, and hospitable. The Arabs of pure blood belonging to Egypt are chiefly

Modern Egyptians.

Bedouins who dwell in tents in the desert, and number about 400,000. The native Christians, termed Copts, are the recognized descendants of the ancient inhabitants. They are generally employed as clerks and accountants in government and mercantile offices. Besides these there are about 20,000 Turks, the ruling class, and Armenians, Berbers or Nubians, and Jews.—Agriculture is the chief pursuit, and furnishes all the staples of export. The exports of Egypt amounted in 1861 to \$19,465,000; in 1865 to \$87,679,000; in 1867 to \$51,950,000; in 1869 to \$55,969,312; in 1871 to about \$52,000,000. The exceptional amount in 1865 was altogether due to the English demand for cotton, which in that year was exported from Egypt to the value of \$77,215,000, while in 1867 it fell to \$33,000,000, and in 1868 to \$29,000,000. Next to cotton, the most valuable article of export is wheat, which in 1868

was exported to the value of \$6,548,000. The export of beans, peas, lentils, barley, and dates is also increasing. The export of sugar promises to become of great importance; it rose from \$200,000 in 1867 to \$855,000 in 1868, and has considerably increased since. The imports amounted to \$26,800,000 in 1865, and to \$29,000,000 in 1867. The principal articles are timber, copper, coal, woollen, cotton, and silk goods, ivory, amber, gums, drugs, tin-ware, paper, oil, jewelry, sugar, glass, tobacco, spices, and coffee. The foreign commerce is chiefly with Great Britain, which receives about 75 per cent. of the Egyptian exports, and with France, Germany, and Austria. An extensive trade by means of caravans is maintained with the interior of Africa. The manufacture of firearms, and of cotton, silk, and woollen goods, is carried on extensively in establishments founded and directed by the government. The length of the state railways in Egypt in January, 1872, amounted to 649 m., 286 m. of which had double tracks. The only private railway, that from Alexandria to Ramleh, is 5 m. long. The railway from Cairo to Suez was abandoned in 1868. The telegraphic lines in operation in 1872 were 3,900 m. (560 m. being private), and had 8,300 m. of wire. Numerous sailing vessels and smaller craft ply on the Nile and the navigable canals, especially in Lower Egypt, where the principal towns are beginning to maintain regular steamboat communication: The movement of shipping in the Suez canal in 1871 was 765 vessels, of an aggregate burden of 761,410 tons. The number of arrivals at the port of Alexandria was 2,921 vessels, and at Port Said 1,275 vessels, exclusive of 87 men-of-war. There were forwarded in 1871 by the Egyptian mail 1,490,000 letters, by the Austrian 124,000, by the Italian 135,000, by the Greek 30,000.—At the head of the government stands the khedive, a vassal of the sultan of Turkey, whose office is hereditary from father to son. According to the hatti-sherif and firman of investiture of 1841, Egypt must maintain the fundamental laws of the Ottoman empire, raise taxes in the name of the sultan, issue coin with his name, and pay an annual tribute. The parliament consists of deputies elected for a period of three years. The central government is vested in the ministries of foreign affairs, finance, war, navy, public works, and the interior. The cabinet of the khedive comprises a councillor, a secretary, a seal-bearer, a treasurer, and a chief of interpreters. There are also councils of agriculture, of commerce, and for the preservation of antiquities. There are four principal courts of justice, whose seat is at Cairo: that of the chief of police, which summarily decides petty cases; that of the *cadi*, or chief judge; that of the mufti, or chief doctor of the law; and that of the pasha's divan. There is also a *cadi* in each town and village, who dispenses justice on religious transgressions, inheritance, right of succession, &c.; and each province and subdivision of the coun-

try has a *mudir* or governor who administers the criminal law. The revenue increased from £4,813,970 in 1864 to £10,571,048 in 1873, derived from taxes on land, tithes, tolls, &c., and from railways and customs duties. The total revenue in the 10 years ending Sept. 10, 1873, was £98,102,720, and the expenditure £112,561,784, of which about £6,000,000 were tribute to the sultan, £10,000,000 the cost of railways, and £16,000,000 that of the Suez canal. A new loan of £11,700,000 was contracted in 1873, making the total debt £49,000,000. The army was formerly limited to 18,000 men, but in consideration of the increase of the annual tribute from 80,000 purses to 150,000, under Said Pasha, permission was given to raise the army to 30,000. The navy in 1870 consisted of 12 steamers (3 yachts, 2 frigates, 2 corvettes, 4 screw gunboats, and 1 aviso).—Schools for primary instruction are connected with the mosques. The number of pupils is rapidly increasing, and in 1871 was estimated at 60,000. The university of Cairo, called *el-Ashar* (the Blossom), has students from all parts of Africa, from Turkey, and even from the Sunda islands. Education has made great progress during the reign of Ismail Pasha, especially since the establishment in 1868 of government schools in the large towns. These schools were attended in 1870 by about 4,000 pupils who received support from the government. The schools embrace both elementary and secondary education. In the secondary department the students take a three years' preparatory course, after which they are transferred to one of the special schools. These special schools are: a polytechnic school (which prepares the way for either the school of administration or the military academy), a law school, a philological and arithmetical school, a school of arts and industry, a medical school, and a naval school. In 1871 Prof. Brugsch, of the university of Göttingen, was called by the Egyptian government to Cairo, to establish there an academy for archæology, and in particular for Egyptological studies. The periodical press is still in its infancy, and almost entirely in the hands of foreigners. There were published in 1872, in the Arabic language, an official paper and a weekly journal called *Madi el-Nil* ("Valley of the Nile"), in Cairo, and a number of French, Italian, and Greek papers in Alexandria, two of which, *L'Égypte* and *Manifesto Giornaliero*, were dailies. A press bureau is connected with the department of foreign affairs.—The history of Egypt divides itself into six great periods, each characterized by a different race of rulers: 1, that of the Pharaohs, or native kings; 2, of the Persians; 3, of the Ptolemies (Greeks); 4, of the Romans; 5, of the Arabs; 6, of the Turks. The main sources of its history under the Pharaohs are the Scriptures, the Greek writers Herodotus, Diodorus, and Eratosthenes, some fragments of the writings of Manetho, an Egyptian priest of the 3d century B. C., and the hieroglyphic inscriptions on the

monuments, that is, on the temples, tombs, and other buildings of ancient date. From works written on rolls of papyrus, found in the tombs, information has also been derived by recent Egyptologists. From the Scriptures we learn that the Hebrew patriarch Abraham went into Egypt with his family because of a famine that prevailed in Canaan. He found the country ruled by a Pharaoh, the Egyptian term for king. The date of Abraham's visit, according to Usher's chronology of the Hebrew text of the Bible, was about 1920 B. C.; according to the Septuagint, about 2550; while Bunsen fixes it at 2876. Nearly two centuries later Joseph, a descendant of Abraham, was sold into Egypt as a slave to the captain of the guards of another Pharaoh, whose prime minister or grand vizier the young Hebrew eventually became. Joseph's father, Jacob, and his family, to the number of 70, accompanied, as Bunsen conjectures, by 1,000 or 2,000 dependants, followed their fortunate kinsman into Egypt, where they settled in a district called the land of Goshen. There they remained until their numbers had multiplied into two or three millions, when under the lead of Moses they revolted and quitted Egypt to conquer and possess the neighboring land of Canaan. The date of their exodus, according to Usher, was 1491 B. C., after a sojourn in Egypt of about 210, or at most of 430 years. Bunsen assigns the date to 1320, and maintains the duration of the sojourn in Egypt to have been 1,434 years. The most recent Egyptologists generally agree that it occurred about 1300 B. C., and identify the Pharaoh of the exodus with Merneptah I. (pronounced Mernephtah in Lower Egypt), the Menephtes of Manetho, one of the last kings of the 19th dynasty. From the exodus, for several centuries, the relations between the Hebrews and the Egyptians appear to have been generally friendly, until in the 5th year of the reign of Rehoboam, about 970, Shishak, king of Egypt, conquered and plundered Jerusalem, an event the occurrence of which is attested and confirmed by the monuments.—The first of the Greek authorities upon Egypt, Herodotus, visited the country about the middle of the 5th century B. C. His knowledge of its history was derived from conversation with the priests of various cities, with whom he talked by means of interpreters. He did not himself understand the language, and his Greek guides appear to have told him many vulgar fables and legends, while what he gathered from the priests he seems to have imperfectly understood. They told him, he says, that Menes was the first king of Egypt, and was succeeded by 330 monarchs, of whom one, Nitocris, was a queen. None of them were distinguished, and none of them left any monuments worthy of note, except Mæris, the last of the 330, who constructed the artificial lake which bears his name. He was succeeded by Sesostris, who conquered Ethiopia and the greater part of Europe and Asia. His successors were

Pheron, Proteus (who was contemporary with the Trojan war), Rhampsinitus, Cheops, Cephren, and Mycerinus. The last three kings built the three great pyramids. Mycerinus was succeeded by Asychis, and Asychis by Anysis, in whose reign Egypt was conquered by the Ethiopians, who held it for 50 years under King Sabaco. At the expiration of the half century they voluntarily abandoned the country and retired to Ethiopia. The next king of Egypt was Sethos, between whom and the first king Menes, the priests told Herodotus, there had been 341 generations, a period of 11,340 years. Sethos was succeeded by 12 kings, who reigned jointly, and together built the labyrinth, which Herodotus thought surpassed all the works of the Greeks, and was even more wonderful than the pyramids themselves. After the lapse of some years, Psammetichus, one of the 12 kings, dethroned the others and made himself sole sovereign of Egypt. He was succeeded by Necho, Psammis, and Apries, the last of whom Herodotus calls the most prosperous king that ever ruled over Egypt. But in the 25th year of his reign a rebellion broke out which was headed by Amasis. Apries was defeated and put to death, and Amasis became king. Amasis was succeeded by his son Psammenitus, at the very beginning of whose reign (525) Egypt was invaded and conquered by the Persians under Cambyses. Diodorus, the next of our Greek authorities, was in Egypt about 20 B. C. Like Herodotus, he begins the line of Egyptian kings with Menes, who, he says, was succeeded by 52 monarchs, reigning 1,400 years. These were succeeded by Busiris I., and seven or eight generations later by Busiris II., who built Thebes. Later still reigned Osymandyas, and after eight more generations Uchoreus, who built Memphis, and after 15 more generations was succeeded by Myris or Mæris. Diodorus also relates the exploits of the great conqueror Sesostris, whom he calls Sesosis. He computes the whole number of native sovereigns of Egypt at 470 kings and 5 queens, and the duration of the native monarchy at 4,700 years. Eratosthenes, who died about 196 B. C., was a native of Cyrene, and was made librarian of the Alexandrian library by Ptolemy III. He wrote a work on universal chronology, fragments of which have been preserved by Syncellus and others. His computation of Egyptian chronology, so far as it goes, has been adopted by Bunsen. Manetho was high priest of Sebennytus about 280 B. C. He wrote a history of Egypt for the information of the Greeks, of which only some extracts have reached us in the works of later writers, who do not agree in their transcription of the most important part of these remains, which is a list of the dynasties and sovereigns of Egypt from the earliest period to the end of the Persian rule. But notwithstanding the occasional discrepancies produced by careless or fraudulent copyists, these "dynasties" of Manetho are

of the highest value to Egyptian history, and their general authenticity has been fully established by comparison with the monuments. There were 31 dynasties which reigned successively in Egypt, numbering upward of 300 kings, the sum of the years of whose reigns from Menes to Nectanebo II. (about 350 B. C.), the last king of the 30th dynasty, which was succeeded by the last Persian, was 3,555 years. "This succession of time," says Bunsen, "the vastest hitherto established anywhere in the old world, is now also the best authenticated. It is based upon lists of kings and their regnal years; and these lists are corroborated and elucidated by contemporary monuments up to the 4th dynasty, with slight breaks; an authentication which is as unexampled as its extent." The era of Menes, according to Bunsen, was 3643 B. C.; according to Lepsius, 3893; according to Brugsch, 4455; according to Mariette, 5004. Wilkinson remarks of Menes that the frequent occurrence of a similar name in early history, as Manes, the first king of Lydia, the Phrygian Manis, the Minos of Crete, the Indian Menu, the Thibetan Mani, the Siamese Manu, the German Mannus, and others, may seem to assign him a place among mythical beings; but that the Egyptians themselves believed him to be a real personage, and accepted the recorded events of his reign as undoubted facts. It is still in dispute among Egyptologists whether the first 17 dynasties which succeeded Menes were consecutive. It is maintained however by the latest writers, that the dynasties, with considerable exceptions, were consecutive, and that the kings enumerated reigned over the whole of Egypt. In the following table we give a list of the dynasties with their capitals, the duration of their reigns, and the periods of their accession according to Mariette:

DYNASTY.	Capital.	Duration.	Date B. C.

Of the 1st dynasty, founded by Menes, no monuments exist. The second king, Teta, is mentioned in later records as having built a palace at Memphis and as the author of books on surgery. The fifth king, Hespri, was the author of sacred writings. The 2d dynasty comprised nine kings, of whom the second, Kekeu, built the pyramid at Sakkara, the oldest monument in Egypt. He also established, it is said, the worship of some sacred animals, among others the bull Apis, who was considered to be a living manifestation of the god Ptah. The eighth king of this dynasty, Sesocris, is said to have been a giant. Some remains of sculpture made in the latter reigns of this dynasty have been found, marked by a rudeness of style showing that Egyptian art was still imperfectly formed. The 3d dynasty, whose seat was at Memphis, was founded by the earliest of Egyptian conquerors, Seker-neferke, who subdued the Libyans. Snefru, the last but one of the dynasty, subdued some of the nomadic tribes of Arabia. The pictures in the tombs of his reign show Egyptian civilization as completely organized as it was 4,000 years later. Nearly all the animals now used by man were domesticated, and the Egyptian language seems to have been completely formed. The 4th dynasty was like the 3d of Memphis, and the three great pyramids were built by three of its kings, Khufu, Shafra, and Menkara. Khufu was warlike, and won victories over the Ann, a people of northern Arabia. These kings built also the great sphinx at Gizeh, which was probably finished in the reign of Shafra, and near it a vast temple which was for ages buried in the sand of the desert, but has recently been discovered by M. Mariette. The splendor and wealth of Egypt seem to have been very great under this dynasty, but the people were oppressed and became rebellious, and the dynasty ended in a revolution about 3951 B. C. The 5th dynasty came originally from Elephantine, and numbered nine kings, whose reigns seem to have been prosperous and peaceable. Many monuments of this period remain, and from the sculptures and the paintings in the tombs it is evident that a high state of civilization existed, and that art had attained a remarkable degree of excellence. Some of the writings of this age on sheets of papyrus have been found in the tombs. The national library of France possesses a book dated in the reign of Assa-Tatkera, the last king but one of this dynasty, written by an old man of the royal family named Ptah-hotep. It is a sort of handbook of good manners for young people, a treatise on practical morality, somewhat in the style and tone of the writings of Confucius. Filial obedience is inculcated as the basis of all good order. On the death of the last king of the 5th dynasty, a new family, of Memphian origin, came to the throne. The first king, Ati, was, it is said, after a stormy reign of 30 years, assassinated by his guards. His son and successor, Pepi Merira, was very powerful and

warlike, and has left monuments in all parts of Egypt. He conquered the Wa-Wa, a nomadic negro nation who had invaded Egypt. A second Pepi, surnamed Nefer-kera, is said to have reigned 100 years, but of this long reign little is known except that toward its end troubles broke out, the most serious and violent that had yet occurred in Egypt. The next king, Mentemsaf, was assassinated after a reign of a year. His sister Neit-aker, whom the Greek writers called Nitocris, was celebrated both for beauty and wisdom. She seized the reins of government, and for 12 years struggled energetically against the revolutionary party. At the end of that time she invited the murderers of her brother to a banquet in a subterranean gallery, and drowned them all by letting in the waters of the Nile upon them through a secret culvert. She soon after committed suicide to avoid the vengeance of their partisans. With her ended the 6th dynasty. A period of convulsion, dismemberment, and weakness succeeded, which lasted 436 years, and during which four dynasties reigned of whose history scarcely anything is known. The primitive art of Egypt attained its highest point under the 6th dynasty; but for more than four centuries afterward art and civilization seem to have been eclipsed by circumstances of which we can only conjecture that the kingdom had been subdued by foreign invaders. Memphis and Heracleopolis were the capitals during this dark period. It terminated with the 10th dynasty, or nearly 20 centuries after Menes. These 20 centuries comprise the period known among modern Egyptologists as the old empire. A new monarchy, which Egyptologists call the middle empire, began 3064 B. C. with the accession of the 11th dynasty, whose capital was Thebes. That city seems to have been founded during the period of anarchy, or at least of darkness, which followed the extinction of the 6th dynasty. From it came the six kings of the 11th dynasty, whose names were alternately Entep and Mentu-hotep, and who carried on for nearly two centuries an energetic struggle with the kings of the Delta, who had set up a separate kingdom and were perhaps foreign conquerors. The end of the struggle was the subjection of all Egypt to the Theban dynasty, one of whose monarchs is constantly designated on the monuments by the epithet "great." The 12th dynasty was also Theban, and was probably related to the 11th. All its monarchs were called Osortasen or Amenemhe, except the last, a queen named Ra-sebek-nefru. Its epoch was one of prosperity, of peace at home and of conquest abroad. Osortasen I. made great acquisitions in Arabia and in Nubia. The record of his Arabian exploits is engraved on the rocks of Sinai. Osortasen III. was also a great conqueror, and subjugated Ethiopia. Among the works of this dynasty were the labyrinth and Lake Moeris. This lake, of which some remains yet exist, was the work

of Amenemhe III., and showed a high degree of engineering skill. The art of sculpture under this dynasty was brought to a degree of perfection not subsequently surpassed. Its chief characteristics were delicacy, elegance, and harmony of proportion. The history of the 13th dynasty, which lasted from 2851 to 2398 B. C., was one long series of revolutions and internal and external troubles. Its kings were 16 in number, nearly all being named either Sevek-hotep or Nofre-hotep. No building of this dynasty remains, and the history of its kings is consequently very obscure. Toward its close, about 2400 B. C., a rival and probably a rebel line seems to have established itself at Xoïs in the Delta, where it reigned for 184 years, and constituted the 14th dynasty. This division of the nation into two hostile kingdoms doubtless facilitated and perhaps instigated the conquest of Egypt by the Hyksos or shepherd kings, who invaded the country about 2214, and soon made themselves masters of it, and ruled it for four centuries. According to Mariette and others, these Hyksos were a combination of the nomadic hordes of Arabia and Syria. The chief of them, the tribe that led the rest, were the Hittites of the Bible, who are called Khatas by the Egyptian monuments. They treated the Egyptians with great cruelty, and defaced and destroyed the temples and other monuments with savage violence. Their kings established their capital at Avaris on the northeastern frontier, where they maintained a powerful garrison. These monarchs formed the 15th, 16th, and 17th dynasties. In course of time, like the Tartars in China, they were subdued by the superior civilization of the people they had conquered, and adopted Egyptian manners and names. The last king of the 17th dynasty, whose name was Apepi, reigned 61 years, and he is considered by many authorities the Pharaoh in whose reign Joseph came into Egypt and was made governor over all the land. Soon after the conquest by the shepherds many of the Egyptians took refuge in Ethiopia, whence in time they gradually returned and founded a native kingdom at Thebes, which probably paid tribute to the shepherds, who remained directly dominant in Middle and Lower Egypt. Of these Theban kings we know the names of only two, Tiaaken and Kames. The shepherd king Apepi required his vassal Tiaaken to worship his Canaanitish god Sutekh or Set, whom he had added to the Egyptian pantheon and to whom he had built a temple. The Theban refused, and war began. The contest was long and severe. It continued through the reign of Tiaaken and of his successor Kames, and terminated in that of Ahmes, the son of Kames. The shepherds were driven at last into their great fortress Avaris, where they were besieged by the Egyptians, and were finally permitted by treaty to depart into Palestine, though a portion of them were allowed to remain and cultivate a district in the east of Lower Egypt, in much

the same way as the Israelites were allowed to settle in the land of Goshen. After the expulsion of the shepherds, King Ahmes, who had married an Ethiopian princess, turned his arms toward Nubia, which had revolted, and in a few battles completely subdued the rebels. The remainder of his reign was occupied in works of peace, in rebuilding the temples and the palaces destroyed by the shepherds. The civilization of Egypt appears to have revived immediately with great force, and trade, agriculture, and the arts to have received a fresh and vigorous expansion. The disasters and depression of four or five centuries of foreign rule seem to have been repaired in a few years. The buildings of this period are among the best in Egypt, and jewels of great richness and of incomparable workmanship have recently been found on the mummy of Queen Aah-hotep, the mother of Kames. Ahmes is considered the founder of the 18th dynasty, the greatest and most magnificent that ever reigned in Egypt (1793-1462 B. C.; according to Rawlinson much later, 1525-1324). With it opens the third historical period, known as the new empire. From this time for several centuries Egypt was one of the greatest powers of the world, and her influence was strongly felt by all surrounding nations. Her kings made great efforts to conquer Asia, from which quarter experience had shown that danger was chiefly to be apprehended. They also maintained the traditional policy, inherited from the kings of the 12th dynasty, of endeavoring to subjugate the whole valley of the Nile, which they regarded as belonging legitimately to Egypt. During the whole period of this dynasty, therefore, their armies were waging war either to the south or to the north-east. Ahmes conquered Canaan, and his successor Amen-hotep, called Amenophis by the Greeks, subdued a large part of Arabia. The next king, Thothmes I., defeated the Rotennu or Syrians near Damascus, crossed the Euphrates, and subdued Mesopotamia, which the Egyptians called Naharaina. In these wars the Egyptians first learned the use of horses, which seem previously to have been unknown to them, but which thrived exceedingly in the rich pastures of the valley of the Nile, and as well as chariots played from that time forward a very conspicuous part in their wars. Thothmes I. reigned 21 years, and was succeeded by his son Thothmes II., whose reign was short. His successor was his brother Thothmes III., a child, whose elder sister Hatasu (or Amen-set) governed for many years in his name. Her reign was brilliant, and distinguished by the conquest of Yemen or Arabia Felix, a rich and fertile country, the possession of which was always greatly coveted by the Egyptian monarchs. Among the works of Hatasu are the temple of Deir el-Bahri and the two great obelisks of Karnak, erected to the memory of her father. Under Thothmes III. Egypt attained the summit of her glory and power. Her internal affairs were well administered, and her

empire extended over the countries now called Nubia, Abyssinia, Arabia, Syria, Mesopotamia, Kurdistan, and Armenia. A great fleet, manned probably chiefly by Phœnician sailors, was created on the Mediterranean, with which Cyprus and Crete and the islands of the archipelago, the southern coasts of Greece, and probably the south of Italy, were conquered, and all northern Africa as far west as Algeria, where monuments of Thothmes III. have been found. In Egypt itself his monuments are very numerous, and are all in the best style of architecture and of the highest excellence of workmanship. He was succeeded by Amen-hotep or Amenophis II., whose reign was short, as was that of his successor Thothmes IV. The next king, Amen-hotep III., reigned at least 36 years, and was a great builder. His monuments are remarkable for their grandeur and for the perfection of their sculpture. He built the temple at Luxor and made great additions to that at Karnak, and erected the famous colossal statue at Thebes known to the Greeks and Romans under the name of Memnon. His son and successor Amen-hotep IV., whose mother, Queen Taia, was not an Egyptian, but a woman of some fair-haired, blue-eyed northern race, attempted, apparently under her influence, to reform the religion of Egypt, and to establish in place of polytheism the worship of one God. He closed the temples and effaced the images of the deities, abandoned Thebes and established his capital at a place now called Tell el-Amarna, where he erected monuments on which the ceremonies of his new worship are represented, bearing a singular resemblance to the external forms of Israelitish worship in the wilderness as described in the books of Moses. The persecution of the Israelites which led to their exodus seems to have begun shortly after this period; and it has been conjectured that the monotheism of Amen-hotep IV. may have had its origin in Hebrew influence, and that the reaction which followed his attempt at religious reformation may have caused the persecution. But the history of Egypt at this period is still very obscure, and nothing is known with certainty except that after the death of Amen-hotep IV. the kingdom became a prey to factions, whose chiefs seized the supreme power and followed each other at short intervals. Finally, however, the legitimate heir to the throne, Har-em-Hebi, the last son of Amen-hotep III., established his authority and reigned for nearly 40 years. With him ended the glorious 18th dynasty. The first Pharaoh of the 19th dynasty was Rameses I., a grandson of Har-em-Hebi. His reign was very short, and he was succeeded by Seti I., the Sethos of the Greek writers, who seems to have been not his son but his son-in-law, and to have been, strangely enough, of the shepherd race who still remained settled in the eastern part of the Delta. He was one of the greatest of the Pharaohs, and was distinguished not only as a conqueror but as a builder. He erected

the great temple of Osiris at Abydos, brought to light by recent excavations, and built also the famous "hall of columns" in the palace at Karnak. On the walls of this vast hall his warlike exploits are depicted in an immense series of magnificent sculptures. The Asiatic subjects of Egypt had revolted during the recent period of confusion, and Seti in a series of campaigns, carried as far as the mountains of Armenia, chastised and subdued them and re-established the supremacy of Egypt over western Asia. He reigned probably about 30 years, and was succeeded by his son Rameses II., whose reign lasted for 66 or 67 years. Rameses II. was the greatest builder among the Pharaohs. The two magnificent subterranean temples at Ipsambul in Nubia, the Ramesseum of Thebes, a large part of the temples of Karnak and Luxor, and the small temple at Abydos, are his works. He built also large edifices at Memphis, at Tanis, and in the Fayoom. He was also a great warrior, and made many campaigns against the tribes of the Upper Nile, who revolted at the beginning of his reign and were subdued with difficulty. While he was engaged with them in Ethiopia the subject nations of Asia deemed it a good opportunity to throw off the Egyptian yoke, and Armenia, Assyria, Mesopotamia, and Syria all revolted at once, probably by concert, and drove out the Egyptian garrisons. The Khitas or Hittites, the old enemies of Egypt, headed the rebellion, which was only subdued after a long contest, in which Rameses won high renown by his personal prowess. From these wars, and from those of his predecessors Seti and Thothmes, the Greek writers formed the legend of Sesostris, the great Egyptian conqueror, whose name was a modification of Sesu-Ra, a title given by the people for some unknown reason to Rameses during his life. The Greek accounts, which represent Sesostris as having conquered Media, Persia, Bactria, and India, are mere fables; the armies of the Pharaohs never penetrated much beyond the Tigris. Nor are the Greek legends of the internal government of Egypt under Sesostris confirmed by the real annals of Rameses, who seems to have been a cruel tyrant, and to have built his great monuments by the forced labor of prisoners of war and by oppressing his own subjects, especially the Semitic tribes who under his predecessors had settled in the Delta and were peaceably cultivating the land. Among these were the Hebrews, who had now grown very numerous, and whose increase Egyptian tyranny finally sought to check by dooming all their male children to death. The last days of this monarch show a marked decline in the arts, especially of sculpture, and also a decay of military power. Egypt was invaded by men of northern race, apparently Pelasgians, who came by sea and laid waste Lower Egypt. They finally seized the western part of the Delta and drove out the native inhabitants, and when the aged Rameses died a considerable part of his kingdom was in the

hands of these foreign barbarians. He was succeeded by his son Merneptah, who established his capital at Memphis, and at the very beginning of his reign had a contest with the northern settlers of the Delta, who sought to extend their dominion over all Egypt, but were finally defeated. A short time after this struggle is supposed to have occurred the exodus of the Israelites, which was a great blow to Egypt by depriving it of millions of industrious people, not to speak of the calamities described in the Scripture narrative. A few years later, while Merneptah still reigned, another disaster befell Egypt. A body of foreigners employed in forced labor at the granaries revolted to the number of 80,000, and called to their aid the Khitas, who invaded Egypt with such force that the king could not resist them, but retired to Upper Egypt, where he died, leaving the country full of foreign invaders and his son and heir Seti, a boy five years old, concealed for safety in Ethiopia. On the death of Merneptah a prince of the royal family usurped the throne, and succeeded in a few years in driving out the foreigners. His son Merneptah II. succeeded him, and was for a time recognized as king by Prince Seti, who received from him the title of viceroy of the southern provinces. But on arriving at manhood Seti claimed the throne and succeeded in attaining it. His reign was long, but no particulars of it are known. He died without children in 1288, and with him ended the 19th dynasty. Seti II. was succeeded by Nekht-Set, the founder of the 20th dynasty, whose reign was short and unimportant, but whose son and successor Rameses III. was one of the most eminent of the Pharaohs. He was a great soldier, though his wars were entirely defensive ones. His military genius preserved the empire from the barbarians who attacked it on every side. After his death an obscure period of a century and a half occurred, during which there were 11 or more kings named Rameses, under whom the kingdom was dismembered and again overrun by foreigners. A rival dynasty, the 21st, arose at Tanis in Lower Egypt, and after a prolonged struggle with the Pharaohs of Thebes succeeded in establishing their authority over all Egypt. One of this dynasty, whose name was Psu-en-sa, bestowed his daughter in marriage on Solomon, king of Israel. This dynasty lasted only 130 years, and was succeeded by the 22d, whose seat was at Bubastis, and whose names are almost all Assyrian, such as Nimrod, Tiglath, and Nabonasi. The first of this dynasty was Sheshonk, the Shishak of the Bible, who conquered Judah and plundered Jerusalem about 970. The duration of this dynasty was 170 years, and it was succeeded in 810 by the 23d dynasty, whose capital was Tanis. It comprised only four kings, though there were several pretenders and usurpers whose names are found on the monuments. The 24th dynasty consisted of a single king, Bocchoris, the Bocchoris of the Greeks, who reigned six years at Sais. He

was succeeded by the 25th dynasty, the founder of which was Shabaka, an Ethiopian, the Sabaco of the Greeks, the So of the Bible, who about 725 invaded Egypt with an army of Nubians and negroes and conquered it completely. He took Bokenranf prisoner, and to strike terror into the people caused him to be publicly burned alive. This Ethiopian dynasty consisted of four kings and lasted 50 years, during most of which term it was at war with the Assyrians, by whom Egypt was repeatedly invaded and conquered. The last Ethiopian king, Rot-Amen, at last voluntarily evacuated Egypt and retired to the upper Nile. Two years of anarchy followed, at the end of which Egypt was ruled for 15 years by a confederacy of 12 chiefs, one of whom, Psammetik (Psammetichus), at the end of that period dethroned his colleagues, expelled the foreigners, and made himself master of all Egypt from the cataracts to the sea. He founded the 26th dynasty, whose capital was Sais, and whose duration was 138 years. Under this dynasty Egypt, according to the Greek writers, was more prosperous than she had ever been before. She became wealthy by trade with the Greeks and other foreigners who now flocked into her ports, and who were enlisted in great numbers as mercenaries in her army. But her national spirit was corrupted; the military caste, disgusted by the favor shown to foreigners, emigrated in a body to Ethiopia; and when about 525, at the beginning of the reign of Psammetik III., the country was invaded by the warlike Persians led by Cambyzes, little resistance was offered by a people who had lost all aptitude for arms, and Egypt became a Persian province governed by a satrap. The people frequently revolted and were as often subdued, but at length, about 405, they succeeded in driving out the Persians, and with the aid of Greek auxiliaries maintained their independence under a series of native monarchs, the last of whom was Nectanebo II., who was conquered and dethroned by Ochus or Artaxerxes III., in 346. Egypt continued a Persian province only till 332, when it was conquered by Alexander the Great.—Of the manners and customs, mode of life, and social condition of the ancient Egyptians, we can form a very satisfactory opinion from the representations on the monuments. It is evident from their testimony that at a very early age the Egyptians were a highly civilized people, wealthy, industrious, with a fully organized society, and great proficiency in arts, manufactures, and agriculture. The fertile soil of the Nile valley was highly cultivated. A great number of workmen were employed in weaving and dyeing rich stuffs. The arts of working in metals, of making porcelain and glass, and of preparing enamel and mastic for mosaics, had attained a high degree of perfection. The rich products of Egyptian industry were exported to the most distant countries. The progress of the Egyptians in sculpture and painting was hampered by re-

ligious restraints, which prevented their development beyond a point which was early reached. In architecture, however, they occupy perhaps the most distinguished place among the nations. No people has equalled them in the grandeur, the massiveness, or the durability of their structures. A competent authority, Fergusson, the author of the "Illustrated Handbook of Architecture," says: "Taken altogether, perhaps it may be safely asserted that the Egyptians were the most essentially a building people of all those we are acquainted with, and the most generally successful in all they attempted in this way. The Greeks, it is true, surpassed them in refinement and beauty of detail, and in the class of sculpture with which they ornamented their buildings, and the Gothic architects far excelled them in constructive cleverness; but besides these, no other style can be put in competition with them. At the same time neither Grecian nor Gothic architects understood more perfectly all the gradations of art, and the exact character that should be given to every form and every detail. They understood, also, better than any other nation, how to use sculpture in combination with architecture, and to make their colossi and avenues of sphinxes group themselves into parts of one great design, and at the same time to use historical paintings, fading by insensible degrees into hieroglyphics on the one hand, and into sculpture on the other, linking the whole together with the highest class of phonetic utterance, and with the most brilliant coloring, thus harmonizing all these arts into one great whole, unsurpassed by anything the world has seen during the 30 centuries of struggle and aspiration that have elapsed since the brilliant days of the great kingdom of the Pharaohs."—Of the religious system of the Egyptians we possess scanty information. The people were of a peculiarly devout character, and their daily lives, as well as their language, literature, art, and sciences, were strongly influenced by religion. In the earliest ages they recognized only one God, who had no beginning and would have no end; who made all things, and was not himself made. To the last the priests retained this doctrine, and taught it privately to a select few. But in the course of time it became unknown to the multitude, who began to worship the symbols under which the attributes of God were represented. The oldest temples, some of which Mariette has discovered near the pyramids, were without idols or sculptures of any kind. But this primitive simplicity soon gave way to priestly inventions by which the multitude were led into idolatry and polytheism, until at last the people worshipped many gods, and each city or district had its tutelary deity, who in that place was particularly adored, while in the rest of the country he was little regarded. The principal gods were Osiris and Isis, who were worshipped throughout Egypt; Amen, or Ammon, who like Jupiter was held to

be the "king of gods," the especial tutelar deity of Thebes; Num or Knuphis, the god of the cataracts and oases, who in later times under the Romans was called also Ammon, and considered the same as Jupiter; Sale, his wife, who corresponded to Juno; Ptah, the Memphian deity, who symbolized the creative power; the goddess Neith, worshipped at Sais, who may be compared to Minerva; Khem, who represented universal nature, and particularly the generative principle, and whose chief temples were at Coptos and at Chemmis; the goddess Pasht, whose worship prevailed at Bubastis, and who corresponded to the Artemis or Diana of Greek and Roman mythology; Maut, the maternal principle; Ra or Phrah, the sun; Seb, the earth, who was called "father of the gods;" Nepte, the sky, wife of Seb, the "mother of the gods;" Mui, the sunlight; Atmu, the darkness; Thoth, the intellect. Other noted deities were Khons, Anuke, Tafne, Savak, Mandu, Set, Horus, and Athor or Hathor. A great variety of abstract principles and even of animals and vegetables were worshipped by the multitude. To each deity an animal seems to have been held sacred, which was probably regarded as his symbolical representative. Bulls were consecrated to Osiris and cows to Athor; the sacred bull of Memphis, called Apis, being particularly venerated throughout Egypt. A hawk was the symbol of Ra, the ibis of Thoth, the crocodile of Savak, and the cat of Ptah. Of the doctrines of the Egyptian religion little is accurately known. The existence of the spirit after death was believed, and a future state of rewards and punishments inculcated, in which the good dwelt with the gods, while the wicked were consigned to fiery torment amid perpetual darkness. It was believed that after the lapse of ages the spirit would return to the body, which was therefore carefully embalmed and preserved in elaborately constructed tombs.—The government of Egypt was a monarchy, limited by strict laws and by the influence of powerful hereditary privileged classes of priests and soldiers. The priests were the ruling class. They were restricted to a single wife, and if polygamy was permitted to the rest of the people, it must have been very seldom practised. The marriage of brothers and sisters was permitted. The laws were wise and equitable, and appear to have been rigidly enforced. Murder was punished with death, adultery by bastinadoing the man and by cutting off the nose of the woman, forgery by cutting off the culprit's hands. Imprisonment for debt was not permitted, but a man could pledge to his creditors the mummies of his ancestors, and if he failed in his lifetime to redeem them, he was himself deprived of burial. Women were treated with respect, and the laws and customs seem to have been so favorable to them that their condition in Egypt was much higher than in any other nation of antiquity. The military force of Egypt

was a species of hereditary militia, which formed one of the leading classes, and in time of peace cultivated the land, of which it held a large portion. The king's guards, some few thousands in number, were the only standing army. The number of soldiers in the military class is stated by Herodotus at 410,000, which probably included all the men of that class able to bear arms. Their arms were spears and swords, and they were protected by large shields. They were distinguished for their skill as archers, and also used the sling. They do not seem to have been well supplied with cavalry, though they made much use of war chariots.—The researches of modern investigators have established the fact that the ancient Egyptians were of the Caucasian type of mankind, and not of the negro. Their language bore unmistakable affinities to the Semitic languages of western Asia, such as the Hebrew and the Arabic. Herodotus, it is true, speaks of them as black and woolly haired, but the mummies, of which immense numbers remain, prove that his words are not to be taken literally. The shape of their skulls is Asiatic, not African; and the paintings on the monuments show that they were neither black like the negro nor copper-colored like some of the Ethiopian tribes. The true negroes are distinctly represented on the monuments, and in a style of caricature which the Egyptians would not have applied to themselves. There is, however, reason to believe that the Egyptians had mixed largely with the negroes, and from the positive statements of Greek and Roman eye-witnesses there can be no doubt that they were of very dark complexion. We have no certain knowledge of the amount of population under the Pharaohs. By some of the Greek and Roman writers the number of inhabitants at the most flourishing periods is said to have been 7,000,000, a prodigious amount for so small a country, the average number to the square mile, exclusive of the desert, being twice as large as in the most densely peopled lands of modern times. Still, so great was the fertility of the country that the statement is not improbable. The cultivable land is somewhat greater in extent now than it was in antiquity, owing to the wider spread of the inundation of the Nile; and it is computed that if properly tilled it would yield more than is requisite for the food of 8,000,000 people, though without allowing any considerable surplus for exportation. Under the Pharaohs little or no corn was exported, and the land seems to have been carefully cultivated. Another statement of the Greeks and Romans, that at the height of her prosperity there were in Egypt 20,000 cities, is altogether preposterous. The country contained several large and populous cities, the most considerable of which were Thebes, Latopolis, Apollinopolis, and Syene, in Upper Egypt; Memphis, Heracleopolis, and Arsinoë, in Middle Egypt; Heliopolis, Bubastis, Leonto-

polis, Sais, Busiris, Naucratis, Mendes, Tanis, and Pelusium, in Lower Egypt.—The conquest of Egypt by Alexander the Great was much facilitated by the hatred of the natives to their Persian masters. He conciliated the priests by sacrificing to the sacred bull Apis, whom the Persians had treated with indignity; and in order to restore to the people their ancient laws and usages, he established two judgements, with jurisdiction over the whole country, and appointed two eminent Egyptians to these offices, directing also all the Greek officers to regard the customs of Egypt in administering the government. But the greatest and most permanent benefit which the Macedonian conqueror bestowed upon Egypt was the foundation of Alexandria, whose capacities to be made a port of the first class and an emporium for the commerce of the eastern Mediterranean he perceived at a glance while passing through the place on his way to visit the oracle of Ammon. The city which he ordered to be built there became in a few years one of the great capitals of the world and the chief centre of Greek civilization. Alexander effected not merely a political, but a social and intellectual revolution in Egypt, which for a thousand years after the conquest remained essentially a Greek country—the Greeks being the dominant if not the most numerous race. After the death of Alexander, 323 B. C., and the division of his empire among the Macedonian captains, Egypt became subject to Ptolemy, surnamed Soter, an able and enlightened ruler, who after a splendid reign of 38 years abdicated in favor of his son Ptolemy Philadelphus, and died two years afterward. The early part of the reign of Ptolemy Philadelphus was disturbed by civil war with his rebellious brothers, two of whom he put to death. The domestic state of Egypt was greatly improved under his administration, and Upper Egypt, which had been in a turbulent condition for half a century, was reduced to order and made safe for merchants and other travellers. The port of Berenice on the Red sea was constructed, and other cities were built or enlarged, to facilitate the trade with India, which was at that time extensive and profitable. The museum of Alexandria and its famous library, both founded by Ptolemy Soter, were under him and his son at the height of their prosperity. Demetrius Phalereus was librarian, Euclid was head of the mathematical school, and the poets Theocritus, Callimachus, and Philætas were reckoned among the ornaments of the court. The Jews at this time were numerous in Egypt, and with the king's sanction the version of the Old Testament known as the Septuagint was made from the Hebrew into the Greek. The dominions of Ptolemy Philadelphus comprised besides Egypt a considerable part of Ethiopia, together with Palestine, Cœle-Syria, Cilicia, Pamphylia, Lycia, Caria, Cyprus, and the Cyclades. His army is said to have numbered 200,000 foot and 20,000 horse, 2,000 char-

lots, 400 elephants, and a navy of 1,500 ships of war and 1,000 transports. Commerce and the arts, science and literature, directed by Greek genius and Greek energy, were carried to a height of splendor that rivalled the brightest days of the elder Pharaohs. Alexandria, the capital, was a superb city, adorned with magnificent edifices, and preëminent throughout the civilized world as a seat of learning, science, and trade. Ptolemy Philadelphus reigned like his father 38 years (285–247), and was succeeded by his son Ptolemy Euergetes, who had a brilliant and prosperous reign of 25 years. He rebuilt many of the great temples of Egypt and founded others, and his court was thronged by artists and authors. Under his profligate and tyrannical son, Ptolemy Philopator, the kingdom began to decline; and in the reign of the next king, Ptolemy Epiphanes, a minor, the king's guardians were forced to invoke the protection of the Romans against the ambitious designs of the sovereigns of Syria and Macedon, who had formed a combination against Egypt. The result of their interference was that, after a century and a half of turbulence and misrule, under eight sovereigns bearing the name of Ptolemy, the last of whom, Ptolemy XIII., reigned jointly with his sister and wife, the famous Cleopatra, Egypt was reduced to the condition of a Roman province by Augustus Cæsar, 30 B. C. It remained subject to the emperors of Rome for more than three centuries, with the short and doubtful exception of a period when it may have been held by Zenobia, queen of Palmyra. It was looked upon as the most valuable of the provinces of the empire, as the granary of Rome, upon whose harvests the idle and turbulent millions of the imperial metropolis depended for their daily bread. Its history during this long period is a record only of fruitless rebellions and of savage persecutions of the Christians, whose religion had been early introduced and made rapid progress. After the transfer of the seat of the empire to Constantinople, A. D. 330, the Christians of Egypt triumphed over the pagans, and for another period of three centuries its history presents little but theological contests, which not unfrequently broke out into civil strife. The first of these contests was the Arian controversy; Arius, who was pronounced a heretic by the council of Nice (325), being a presbyter of the church of Alexandria, while Athanasius, his orthodox opponent, was archbishop. By the emperor Constantius II. Athanasius was removed from his see and an Arian appointed in his place, while the orthodox Christians were grievously persecuted. When Julian the Apostate became emperor, the pagan mob of Alexandria rose against the Christians and murdered the Arian archbishop, and Athanasius finally regained the archiepiscopate. The emperor Valens appointed an Arian to succeed him, and the persecutions of the orthodox were renewed. Theodosius I. in 379 issued stringent edicts

against paganism, which still held its ground, and in Alexandria numbered among its adherents most of the learned and scientific classes and the students in the schools of philosophy. In compliance with the orders of the emperor, the pagan temples were broken into by the Christians and the statues of the deities destroyed or overthrown. The great temple of Serapis, which had been for ages the most sacred and celebrated of pagan fanes, was plundered and desecrated, and its library of 700,000 volumes despoiled by the mob. The pagans resented these outrages, and took arms in defence of their religion; but after several battles had been fought in the streets, the Christians were victorious, and the pagan leaders were driven from the city. In the reign of Theodosius II., Cyril, archbishop of Alexandria, in 414, expelled every Jew from the city. The pagans were next assailed, and one of their most popular teachers of philosophy, Hypatia, daughter of Theon the mathematician, was brutally murdered. At a later period the theological controversies of Egypt culminated in the complete separation of the Coptic or Egyptian church from the orthodox, whose bishops held a council at Chalcedon in 451, and denounced the Egyptian doctrines as heretical. The animosities generated by these contests alienated the Egyptians from the government at Constantinople, so that they made no opposition when in the reign of Heraclius, in 616, the country was overrun by the forces of the Persian king Chosroes II., who held it ten years, until the outbreak of Mohammedanism so harassed the Persians that Heraclius was enabled to recover the province, only however to lose it a few years later, in 640, when it was conquered by the Arabs, led by Amru, the general of the caliph Omar. For more than two centuries after the Mohammedan conquest Egypt remained a province of the caliphate. In 868 Ahmed the viceroy threw off his allegiance and established an independent kingdom, which lasted 37 years, when the caliphs again reduced it to subjection. After a long period of anarchy, Moez, the fourth of the Fatimite caliphs, who reigned in northern Africa, and were rivals of the caliphs of Bagdad, conquered Egypt in 970, built the city of Cairo, and made it the seat of his government. The Fatimite dynasty ruled Egypt for two centuries. The most distinguished of them was Hakem (died 1021), the prophet and messiah of the Druses, who still look for his return to earth. Adhed, the last of the Fatimites, died in 1171, and was succeeded by his vizier or prime minister, Saladin, the chivalrous and successful adversary of the crusaders. He took the title of sultan of Egypt, and at his death in 1193 was sovereign of a vast empire which his sons divided among themselves, Egypt falling to the share of Aziz. Successive invasions by the crusaders harassed Egypt for the following century, but they were all repelled by the descendants of Saladin, with signal loss to the

Christians. The last and most disastrous of these attacks was made by Louis IX. of France in 1248, who landed with a large army and the flower of the French chivalry at Damietta, but after some successes was defeated and compelled to capitulate with the loss of 30,000 men. A remarkable revolution next took place in Egypt. Saladin and his successors had organized a numerous body of guards, called Mamelukes, composed exclusively of slaves brought from the countries around the Caspian sea. They gradually acquired such power and influence that at length they deposed their lawful sovereign and made one of their own number sultan. For about 130 years these mercenaries controlled the destinies of Egypt, making and unmaking sultans at their pleasure. At length, at the close of the 14th century, the Circassians, from whom the ranks of the Mamelukes had long been largely recruited, overthrew the power of the Turkish Mamelukes and took the government into their own hands. Another century of anarchy succeeded, and in 1517 Egypt was conquered by the Ottoman sultan Selim I. and reduced to a Turkish province. Some of the Mameluke sultans were men of talent and energy, and under their rule Egypt was at times the centre of an extensive though fluctuating empire. The arts were cultivated with some success, as is shown by the mosques and tombs of these sultans at Cairo, which justly rank among the most magnificent and elegant specimens of Saracenic architecture. Under their sway Cairo became the chief seat of Mohammedan learning and intellectual cultivation. For two centuries the Turkish pashas ruled Egypt, which decayed like all the lands subjected to them. But in the 18th century the Mamelukes, who still constituted the military force of the province, gradually regained their former power to such an extent that in 1768, under the lead of their ablest and most influential chief, Ali Bey, they threw off the Turkish yoke and declared Egypt independent. But after four years Ali Bey was betrayed and poisoned, and the authority of the sultan was nominally reestablished. Confusion and civil war between the different factions of the Mamelukes continued to prevail until in 1798 the invasion of Egypt by Napoleon Bonaparte united their chiefs in self-defence. Their famous cavalry was forced to give way before the science and tactics of Europe. In the battle of the Pyramids the Mameluke army was nearly annihilated. The French conquered the whole of Egypt, and held it till 1801, when they were expelled by a British army under Generals Abercromby and Hutchinson. After the departure of the French civil war broke out afresh between the Turks and the surviving Mamelukes, which resulted in 1806 in the elevation to the post of pasha of Mehemet Ali, an Albanian adventurer who had become leader of one of the contending factions. His authority, however, was not firmly established until after a long struggle

with the Mamelukes, 500 of whom he perfidiously massacred in 1811. The dispirited survivors fled to Nubia. Mehemet Ali introduced great reforms into Egypt, in the system of administration, and in the organization of the army and navy. With the aid of European adventurers he armed and disciplined a large native force, and created a respectable fleet. Manufactures of arms, cloths, and other important articles were introduced and sedulously fostered; the commerce of Alexandria, which had dwindled almost to nothing, was revived, and the population of the city was increased tenfold during his reign. Egypt, firmly and moderately governed, enjoyed a state of peace and good order to which it had been a stranger for centuries, and attained a commanding position among the surrounding nations. He carried on a long war with the Wahabees of Arabia, finally conquering them and taking possession of their country in 1818. He next subjected Nubia to his sway. The pasha aimed at complete independence, and so great were his resources that in 1831-'3 he waged a highly successful war with the Turkish sultan, conquered Syria and a great part of Asia Minor, and would have made himself master of Constantinople had not the European powers interfered to arrest the progress of his army, and avert the overthrow of the Ottoman empire. Another war in 1839-'40, though successfully begun, ended with a considerable loss of power, owing to a new intervention. In 1848 Mehemet Ali, at the age of 80, grew imbecile, and his son Ibrahim was invested with the pashalic. Ibrahim died at the end of two months, and was succeeded by his nephew Abbas, who as governor of Cairo had been guilty of the greatest atrocities, for which Ibrahim had sent him into exile at Hedjaz as soon as he entered upon his reign. Abbas erected palaces and castles in the deserts, and withdrew to them for months at a time, without paying any attention to the duties of government. One of his first acts was to abolish the educational institutions established by his predecessors, and his next step was to dissolve the army in order to save the expense of it and increase his personal revenues. He hated Europeans, turned them out of office, and tried to drive them out of the country. The only concession he ever made was to permit an English company to build a railway between Alexandria, Cairo, and Suez. In 1852 Abbas received from the Porte an order to introduce the Tanzimat, the fundamental law of Turkey, dating from 1839, which, while granting greater liberties to the people, diminished the autocratic power of the pasha. He refused at first to obey the mandate; but finding that he was involving himself in difficulties which he would not be able to meet, he issued a firman putting the Tanzimat into immediate effect. The Porte found soon after another opportunity for humiliating the pasha. Abbas treated his relatives with great

cruelty and threatened their lives, and they fled to Constantinople and instituted proceedings against him. But a liberal use of money saved him from great molestations, and the ensuing Crimean war made it necessary for the Turkish government to keep on good terms with him. He furnished a contingent of 15,000 men and large sums of money, besides providing for the maintenance of his troops. In July, 1854, Abbas suddenly died, being assassinated, as is believed, by two Mamelukes in the service of a princess of his family whose life he had threatened. The assassination was kept a secret for nearly a week to gain time for the return of El-Hami, his son, in order to secure to him the viceroyalty, which according to the Turkish law of succession fell to Said Pasha, the fourth son of Mehemet Ali. Said Pasha was however informed of the death of Abbas in time to obtain recognition on the part of the foreign consuls and of the Turkish government. He curtailed the power of the mudirs and sheiks el-beled, instituted a new order of conscription, ordered a more equitable taxation, permitted the sale of produce to other purchasers than the government, and undertook several public works, like the cleansing of the Mahmoudieh canal and the continuation of the railway between Alexandria and Cairo to Suez. But the \$5,000,000 which he spent on the last enterprise were thrown away, as this portion of the railway failed to pay the expense of running, and was abandoned for the road subsequently built from Benha to Suez. The construction of the Suez canal is also due to him. His foreign policy was peaceful. After the close of the Crimean war the only use he was called upon to make of his large army was to check the inroads of the Bedouins, and to advance into the Nubian territories not before annexed, which he put under his protectorate. His reforms failed to bear good fruit during his lifetime, because his extravagance heaped upon the country enormous debts. He died Jan. 18, 1863, and was succeeded by his nephew Ismail Pasha. The dearth of cotton caused by the American civil war induced him to cultivate that plant upon his domains, inviting his people to follow up his experiments; the result is that Egypt has become a very important cotton market. The difficulties that beset the continuance of the excavation of the Suez canal he managed with considerable tact, and he was equally successful, by the aid of an enormous sum of money, in obtaining at Constantinople an avoidance of the Mohammedan law of succession as applied to the viceroyalty of Egypt, and the substitution of succession from father to son. In 1866 he put at the service of the Porte an army of 30,000 men to suppress the rebellion in Candia, and soon after increased voluntarily the amount of his tribute. Toward the end of the year he established a kind of parliament, consisting of 75 members, chosen without regard to religion,

for the discussion of measures that he might wish to submit for approval; but he remained as absolutely the ruler of the country as before. In the following year he obtained from the Porte several concessions on the hattî-sherîf of 1841, which bound Egypt to an observance of the general laws of the Turkish empire, and of the treaties which it made with foreign powers. The sultan gave Ismail power to issue laws relating to the interior administration, tolls, and taxes, and to conclude treaties with other powers in regard to general transit and postal affairs. Ismail thereupon asked for the appellation of *aziz ul-Misr*, sovereign of the land of Egypt, but the sultan granted him instead the title of *khedive*, substitute or viceroy. His subsequent demands for an entirely independent legislation, and diplomatic representation at foreign courts, revealed that his aim was gradually to render himself independent of the Turkish empire. He attempted to force the Porte into granting his request by threatening to withdraw his troops from Candia, and by demanding that his tribute should be reduced to the former amount, and that it should be remitted for the next five years; he even hinted that he might take possession of Candia if his demands were not complied with. It was through the interference of the foreign powers to check his ambitious projects that a war between the sultan and his vassal was prevented. Ismail advanced in 1868 into the countries of the Upper Nile, over which he extended his sway. In the autumn of 1869 he sent out an expedition under Sir Samuel Baker to establish his rule in the lands bordering on the White Nile. In the same year he attempted to negotiate a neutralization of the Suez canal, as well as a loan, while inviting the different sovereigns to be present at the opening festivities. He received soon after an order to reduce his army to 30,000 men; to countermand the ironclads and breech-loaders which he had ordered in France, or, if that was impossible, to transfer them to the Turkish government on payment of their cost; to abstain in future from all diplomatic transactions and from making foreign loans; and to submit for inspection the annual budget of the income and expenditures of Egypt. The khedive's reply was unsatisfactory; he made no concessions, and declared that he would make loans whenever and wherever he wished. The sultan was about to send a messenger to Cairo with the ultimatum to the khedive of obedience or deposition. England and France tried to bring about a more peaceful course, but the sultan declined all interference; he was, however, induced to defer action until after the visit of the European princes at the opening of the canal. At this festivity 10,000 persons of all countries were entertained at the expense of the khedive. The empress of France, the emperor of Austria, and the crown prince of Prussia were present. Before the last guests had left Egypt a note arrived from

the sultan presenting the alternative of submission or war. Ismail had seen that he could not expect armed assistance from the European powers; he therefore issued (Dec. 9) a firman declaring his submission to the will of the sultan. But in the following year he threw another loan on the European market, saying that he offered no other guarantee than his private treasury. The sultan thereupon cut off his credit by a public announcement to the effect that the loan proposed by the khedive had not the support of the laws of the country. This and the subsequent Franco-German war obliged the khedive to abandon for a while his attempt to establish a recognized independence. He has since been busy in carrying out his other plan of getting under his control the whole country extending to Gondokoro and the coast of the Albert Nyanza, about lat. 2° S., in which he has been served by Sir Samuel Baker. The constant wars between the several rulers of Abyssinia since the English expedition afforded the khedive an opportunity to push into that country, and establish over portions of it a sort of military rule, on the pretext of protecting Egyptian trade. Through the other native territories he has drawn a military cordon, and opened roads for traffic. His intention is to transform those regions into an agricultural district; he supplies the chiefs with seed, and holds them under obligation to furnish certain quantities of produce. Thus he has made their stores of ivory, gums, hides, wax, gold, &c., more accessible; and the railways and telegraphs which he is now rapidly building through Nubia, as well as his control over the Red sea and the Suez canal, enable him to secure the wealth of these districts for the benefit of the lower provinces. These efforts of the khedive to secure the prosperity of Egypt restored to him the confidence of the sultan, and on June 8, 1873, a firman was granted which not only confirms the privileges enjoyed by his predecessors, but changes the position of Egypt from a province into an almost sovereign kingdom. The firman authorizes the khedive to make laws and internal regulations; to organize every means of defence, and without restriction to augment or diminish the number of his troops; to contract with foreign powers commercial treaties, and others regulating the position of foreigners and their intercourse with the government and the population; and to contract loans abroad in the name of the Egyptian government, with complete and entire control of the financial affairs of the country. The khedive is forbidden to make treaties bearing on political matters; he can have no agents accredited at foreign courts; the money coined in Egypt must be coined in the name of the sultan; the colors of the Egyptian army and navy must be in no way different from those of the Turkish forces; ironclad vessels must not be built without the permission of the sultan. The khedive retains the privilege of conferring military promotions up

to the rank of colonel, and civil grades to that of *rutbeh-i-sanieh* only. Finally, he is bound to remit every year, in full and without delay, to the Turkish treasury 150,000 purses of tribute.—The following is a list of some of the most important works on ancient and modern Egypt: Denon, *Voyage dans la basse et la haute Égypte* (Paris, 1802); Champollion (the younger), *L'Égypte sous les Pharaons* (Paris, 1814), and *Monuments de l'Égypte et de la Nubie* (1843); *Description de l'Égypte* (26 vols. 8vo, and 12 vols. fol. of plates, new ed., 1820-'30); Lane, "Manners and Customs of the Modern Egyptians" (2 vols., London, 1836); Russeger, *Reisen* (7 vols., Stuttgart, 1841-'50); Bunsen, *Aegyptens Stelle in der Weltgeschichte* (5 vols. 8vo, Hamburg and Gotha, 1845-'57), and more especially the second edition of the English translation, with additions by Samuel Birch (5 vols., London, 1867); Samuel Sharpe, "History of Egypt from the earliest Times to the Conquest of the Arabs" (London, 1846; new ed., 1870); Wilkinson, "Manners and Customs of the Ancient Egyptians" (3d ed., 5 vols., London, 1847), "Handbook for Travellers in Egypt" (1847), "A popular Account of the Ancient Egyptians" (2 vols., 1854), and notes and appendices to Rawlinson's "Herodotus" (1858-'9); Lepsius, *Denkmäler aus Aegypten und Aethiopien* (Leipzig, 1849 et seq.), *Chronologie der Aegypter* (Berlin, 1849), and *Briefe aus Aegypten und Aethiopien* (Berlin, 1852; English translation, London, 1855); Kenrick, "Ancient Egypt under the Pharaohs" (2 vols., London, 1850); Brugsch, *Reiseberichte aus Aegypten* (Leipzig, 1855), *Histoire d'Égypte des premiers temps jusqu'à nos jours* (3 vols., 1859 et seq.; abridged by Mariette for the use of the colleges of Egypt as *Aperçu de l'histoire d'Égypte*, Alexandria, 1864), and *Geographische Inschriften Altägyptischer Denkmäler* (Leipzig, 1857-'60); Uhlemann, *Handbuch der gesammten Aegyptischen Alterthumskunde* (4 vols., Leipzig, 1857-'8); Alfred von Kremer, *Aegypten, Forschungen über Land und Volk* (2 vols., Leipzig, 1863); Chabas, *Voyage d'un Égyptien en Syrie, Phénicie et Palestine* (Châlons, 1866); Dümichen, *Historische Inschriften* (Leipzig, 1867-'9); Ebers, *Aegypten und die Bücher Mose's* (2 vols., Leipzig, 1871-'4); and Stephan, *Das heutige Aegypten* (Leipzig, 1872). EGYPT, Language and Literature of. Nothing is positively known of the origin and chronology of the old Egyptian language. Though very distinct, it indicates some affinity to the Semitic languages, but not as great a relationship as exists between Hebrew, Aramaic, Arabic, and Assyrian. Besides the analogy in the mode of writing, which omits many vowels and gives the words only in skeleton, there are numerous coincidences in the vocabulary. The Berber, Saho, and Galla languages, which

are considered one in origin with Semitic tongues, have also an unmistakable affinity with Egyptian. The Semitic character of the language is specially maintained by Benfey, Ernst Meir, Karl Lottner, F. Müller, De Rouge, Ebers, Brugsch, and Lepsius. Some words, however, are Indo-European, and Pott, Ewald, and Renan have placed Egyptian in that family of languages. Ewald and Renan are of late less positive, and the internal evidence seems sufficient to establish some relationship between Semitic and Egyptian. The history of the development and decay of the language has not yet been traced; only the four distinct graphic systems, hieroglyphic, hieratic, demotic, and Coptic, can safely be confined within chronological limits. The time of the development of the old and full hieroglyphic writing is unknown. It was perfectly understood and freely used in the time of the 3d and 4th dynasties, which renders it probable that the date of its discovery must be placed much earlier than 3000 B. C. The use of this writing was not confined to the sacerdotal classes, as was formerly believed on the authority of the Greeks, but it was employed by all, and for all purposes. Though shorter methods of writing were afterward devised, the hieroglyphic or pictorial representation of the language continued in use for important state documents, inscriptions, and religious compositions, and is found, accompanied by transcriptions in demotic and in Greek, down to the Roman emperor Decius, and, if Lenormant's reading is correct, as late as the usurpation of the government of Egypt by Achilles, who was put to death by Diocletian, A. D. 296. The spread of Christianity in Egypt caused a proscription of the hieroglyphics, because they are full of mythological allusions and sensual figures. The wants of a reading and writing nation led at an early period to the use of linear hieroglyphics in long documents, which subsequently developed into a cursive hand, called the hieratic. The great body of Egyptian literature has reached us through this character, the reading of which can only be determined by resolving it first into its prototype hieroglyphics. It is not possible to fix the time of the first use of hieratic writing; but from the actual preservation of several hieratic papyri of the 11th dynasty, presenting it as a perfectly distinct and well developed mode of writing, it is safe to conclude that it must have come into use long before 2000 B. C. The demotic indicates a rise of the vulgar tongue into literary use, which took place about the beginning of the 7th century B. C., when it was brought into fashion by the great social revolution in the reign of Psammetik (Psammetichus). The oldest demotic papyrus found, now in the Turin museum, dates from the 45th year of his reign, or 620 B. C. The demotic was used to transcribe hieroglyphic and hieratic papyri and inscriptions into the vulgar idiom till the 2d century

A. D., and the gradual transition from the obscure and difficult demotic to the more intelligible Coptic alphabet can be easily discerned. Demotic words were occasionally transcribed in Greek letters, pure Coptic occasionally in the demotic characters, and again demotic in Greek letters, with the sounds not found in Greek preserving their original signs, which was in reality the Coptic alphabet. Coptic is the exclusive character of the Christian Egyptian literature, and marks the last development or final decay of the Egyptian language, which became almost extinct during the last century, and made way for Arabic. (See COPTIC LANGUAGE.)—To understand the varied use of the hieroglyphic signs which make up the language, it is necessary to inquire how this system of writing came to be established. There are traces in Egyptian of a purely pictorial stage, when, as in the North American and Mexican graphic pictures, no attempt was made at recording particular words, but only ideas, which could be read in any language whatever. The great pictures on temple walls and the vignettes in the funeral rituals were probably the original text, expounded subsequently by writing proper, and ultimately preserved as illustrations. After this period of ideographs, or picturing the thing itself instead of tracing signs to suggest the name of it, the Egyptians learned in very early times to use certain objects symbolically to represent abstract ideas, actions, and relations, like goodness and anger, to adore and to rule; thus an irritated ape stood for anger, a lute for goodness, a man lifting his hands for adoration, and a whip for ruling. When no symbol could be found to convey an abstract idea, the discovery was probably made that the sound of its name might be depicted by an object of which the name was the same or nearly the same in sound; just as in English the verb "can" might be represented by a can. This system of suggesting an idea by the picture of a different idea which accidentally had the same sound for its name, became the source of great confusion; and this led to the addition of determinative signs expressing the idea of the hieroglyphs which denoted the sound; and the subsequent desire of using consistently a selection of objects for representing names of other objects than themselves gave rise to the syllabics and alphabets. Hieroglyphs are therefore either ideographs or phonetics. The ideographs (of which there are about 900) are used in various ways: 1, directly, or representing the object itself intended to be expressed; 2, indirectly, or expressing the idea subjectively; 3, tropically, intended to convey only the quality of the object represented; 4, putting the cause for the effect, as a whip for to rule; 5, putting the effect for the cause, as a fallen man for to kill; 6, putting sacred animals and other symbols for the deities to which they belonged. The determinatives are also a subdivision of ideographs, though some pho-

netics are occasionally used as such, and form a class of about 200 hieroglyphs. They convey an idea either directly or indirectly connected with the sense of the word to which they are attached. The determinatives generally follow an ideograph, as  , a lion, where the lion is followed by the hieroglyph of a skin, which is determinative of all animals, and here shows that the lion is to be read *lion*, not simply *r*. Certain words have two determina-

tives, as  , young troops, where

the boy expresses the special nature of the troops, and the three men the determinative conditions or kinds of men. When two determinatives were required, one sometimes preceded and the other followed the phonetic group, or occurred in the second place after a phonetic; and sometimes a phonetic was used as a determinative of a sound not afterward attached to it. Thus the determinative lion which is the phonetic for *r* or *l* is not sounded in

   (*shuk*), to repulse. All groups,

with the exception of the verb to be, pronouns, and prepositions, are followed by a determinative. Every hieroglyphic word in fact consists of two portions: one or more hieroglyphs expressing its sound, and one hieroglyph expressing its idea. All hieroglyphs used phonetically are sounded as the original name of the object which they represent. The so-called alphabets are single syllables composed of two vowels. The syllabic phonetics represent dissyllables, as  (*au*), sometimes written with its second vowel  (*u*);  (*i*), sometimes written  (*i*); and trisyllables, each terminating with a vowel, as   

(*mer*), composed of  (*mu*), =  

(*mu*), and  (*ru*). Some phonetic hieroglyphs are found in the place of others in groups expressing the same idea, and are called homophones. Some alphabetic and syllabic hieroglyphs have sometimes the hieroglyph nearest approaching to their sound placed before them. Phonetics are used to express entire words, principally of an abstract nature, as the verbs to be and to have, the pronouns, prepositions, adverbs, interjections, and other words often used, as  (*neb*), a lord. They often express an entire word with only the aid of determinatives denoting the genus of the idea. Phonetics were also used to complete or indicate the meaning of certain ideographs and determinatives, and in this case are generally placed after them. In a few instances groups of ideographic hieroglyphs are used for phonetic purposes, and again some phonetics occur as determinatives of other pho-

netics. The form  or , which sometimes

interchange, was indifferently prefixed to certain nouns, and  to some verbs. The following is a list of alphabetics in common use:

	Au		Mu		Am
	Âu		Na		Ar
	'Au		Na		As
	Ba		Nu		Âk
	Ba		Pa		Hk
	Bu		Pu		Hn
	Fi		Ra		Hr
	Zi		Ru		Km
	Hâ		Sa		Kr
	Hâ		Su		Mh
	H'a		Su		Mr
	Hu		Su		Nfr
	Iu		Ta		Nn
	Iu		Tu		Pr
	Iu		Ua		Sb
	I		Ui		Sb
	I		Ui		Ts
	K'a		Kh'a		Uh
	Ka		Khi		Ur
	K'a		Shâ		Shm
	K'a		Sha		Sh'n
	Mâ		Shi		Sh't
	Mâ		Shu		Kh'pr
	Mâ		Khnt		

The following are some of the principal deities and important places:

	Amn, Amen, Jupiter.
	Bast, Bubastis, Diana.
	{ Hathar, Athyr, Venus.
	Heshar, Osiris.
	Ptah, Vulcan.
	{ Mut, wife of Amen-Ra, Thermonitis.
	Ra, the Sun.
	Teti, Thoth, Mercury.
	{ Khem or Min, Chem. (Ithyphallic god.)
	Assuru, Assyria.
	Kenus, Nubia.

—The Egyptian wrote with a reed and a palette, with two small oval wells of red and black ink, tracing the hieroglyphs in outline and in black, and commencing paragraphs, directions, and repetitions in red. Hieroglyphical papyri, in rolls about 10 inches wide, and often 150 feet long, present one continuous text of vertical lines, without any separation into pages. The hieroglyphs used in sculpture were generally embellished with colors, and cut from a line to an inch deep, the outline being countersunk, and the details elaborately carved on the inner surface. This protected the texts from ordinary injury and the ravages of time. Most of the hieroglyphs are only relieved by a single color, and it is often necessary to consult the polychromatic texts to determine the character of objects that are now unknown or too crudely represented. Of the colors of the monochromes, black was chiefly used during the 4th and several of the subsequent dynasties, in the 19th dynasty, and still later for sculptures in alabaster; blue, the favorite color of the Egyptians, belongs to all times, but chiefly to the 12th and 18th dynasties; green was used in the 13th, and yellow at the close of the 18th and the commencement of the 19th dynasty. The polychromes imitate, according to Egyptian notions, the color of the objects which they represent: blue, celestial objects, water, liquids, some metals, and edifices; green, trees, vegetable substances, and bronze; red, human flesh, earthenware, and the sun; yellow, light, wood, and some animals; black, hair, and several animals. The

order in which the hieroglyphs are written is not uniform. When used in isolated words explanatory of persons and objects represented, they are distributed promiscuously, either in horizontal or vertical groups, or both. More careful inscriptions have them in vertical or horizontal lines, the columns separated by a broad straight line. Except in a few instances, all the animals and other objects belonging to a certain group, or a sentence, face in one direction, and are to be read in the opposite direction. The signs face generally to the right, whether written in vertical or in horizontal columns, and are read accordingly from right to left; but sometimes the reading is from left to right, although the characters face the other way. Another arrangement is to have half a sentence in vertical and the remainder in horizontal lines, and in some instances the hieroglyphs are without any arrangement whatever, distributed within the limited area of the field of a picture.—The Egyptian language retains always the verbal root of a noun unchanged, the numbers being formed by suffixes and the cases by prefixes. The singular number has the root only; the dual is expressed by repeating it if an ideograph, or by doubling the initial sign of syllables if a phonetic; and the plural by repeating three times the ideograph, syllabic, or phonetic, or by affixing three vertical bars to a masculine noun, and the half circle and three bars to a feminine. The phonetic mode of

forming the plural was to affix  (*u*), to which the three bars were usually added. The indefinite article *ua* scarcely ever occurs, and the definite article only occasionally. In the singular the masculine article is *pa* or *pui*, the feminine *ta*; in the plural, masculine or feminine, *na*, *naiu*, or *nn*, prefixed to the noun. There are only the masculine and feminine genders. Though the masculine is generally expressed by the verbal root of the noun alone, the single bar, *i* (*ua*, one), was sometimes affixed. The verbal root received a *t* (*t*), and at a later period *ts* (*ts*), when feminine. The genitive case is formed in the singular by prefixing a noun of different signification before another, but this form is only elliptical, and during the old empire it was formed by prefixing  (*n*), or by its homophones  and  during the 20th and 21st dynasties. The genitive plural is formed at all periods by  (*nu*), following the noun. The dative is formed by  or  (*n*) when in the sense of possession, and by  (*r*) in the sense of direction. The accusative is like the nominative, and the vocative and ablative are formed by  or  (*m*), and other prepositions.

Simple adjectives are always placed after the

noun which they qualify, compound adjectives before; and they form the masculine, feminine, and plural like the noun. The comparative is formed by adding  (*er*), the superlative by making the noun in the genitive precede, or by trebling the adjective, or by affixing  (*ti*). The phonetic names of the numerals are:

	<i>ua</i> , one.
	<i>sen</i> , two.
	<i>khemt</i> , three.
	<i>ftua</i> , <i>ft</i> , four.
	<i>seb</i> , five.
	<i>ses</i> , six.
	<i>sefkh</i> , seven.
	<i>sesennu</i> , eight.
	<i>put</i> , nine.
	<i>kh'a</i> , a thousand.
	<i>ash</i> , many.

The general mode of expressing them was by repeating the vertical bar as often as required until 10; after which the characters are as follows:

	tens.		millions.
	hundreds.		billions.
	thousands.		infinity.
	tens of thousands.		zero.
	hundreds of thousands.			

Ordinals are formed by prefixing  (*meh*) or affixing  (*n*) to the cardinals. The prefix or isolated pronouns are placed at the beginning of sentences and before substantives and verbs, and are used emphatically; they are *anak*, *anuk*, *nuk*, I; *ntek*, *net*, thou; *ntef*, *su*, *ntes*, his; *nen anen*, me; *nteten*, ye; *ntesen*, *natsen*, *sen*, they. The affix pronouns either express relation or form the paradigms of verbs; they are *a*, my; *k*, masc., *t*, fem., thou; *f*, *u*, *su*, masc., *s*, *st*, fem., he, him, she, her; *n*, *nu*, we, our; *ten*, *ye*, your; *u*, *su*, *st*, they, them, their. When the affix pronouns are found combined with the article, the latter indicates the number and gender of

the object possessed, and the former those of the possessor. The demonstratives are *pen*, *ten*, this; *apen*, *apui*, these; *ua*, one, united with *neb*, all, to express every one; *tennu*, each; *ari*, another; *akh*, who or which, interrogative; *ma*, the relative who or which. The verb to be, when rendered by *pu*, is declaratory, and equivalent to the impersonal it is or was, following the nominative case. It is generally omitted after the pronoun *anuk*, I. When rendered by *ar*, it is often placed at the commencement of sentences, but also at the close, and either precedes or follows the nominative case. The substantive verb *au* is nearly an equivalent of the English verb to be. *Auenti* and *autu* express being or having been. Other forms of the verb to be are *au* and   (*kheper*), the latter generally in the sense of coming into existence or happening. The imperfect is formed by the introduction of  or   (*an*), between the verbal root and the nominative case, and the infinitive by prefixing *r*. The active particle *enti*, being, is often used for the relative form who is and who are, and also for it is and that; it is declined with the articles *pa*, *pui*, *ta*, *tui*, and *t* prefixed. The Egyptian verb is conjugated by prefixes, affixes, and auxiliary, abstract, or substantive verbs accompanied by prepositions. The passive form is less frequently used than the active, and chiefly in the past participle. The moods are the indicative, subjunctive, optative, imperative, and infinitive; the tenses are the same as in other languages. The present tense is formed by affixing the noun or pronoun in the nominative case to the verbal root, as *mer-a*, I love (masc.), *mer-t*, I love (fem.); *mer-k*, thou lovest (masc.), *mer-t*, thou lovest (fem.); *mer-f*, he loves; *mer-s*, she loves; *mer-nen*, we love; *mer-ten*, ye love; *mer-sen* or *su*, they love. The distinction between the perfect and the imperfect is not always strictly observed, and both tenses are formed by prefixing   (*ha*), to stand, often accompanied by the affix  (*n*) or  (*nn*), and also by placing between the auxiliary and the verb  (*her*), about, on the point of, or  (*tu*). The perfect tense can also be formed by the usual affix, as  (*ar*), to make,  (*arna*), I made, which are pronouns preceded by , or  (*n*), or by the auxiliary  (*au*), which serves also to express the future tense. The preposition  (*r*) before the verbal root and after the auxiliary is, however, the usual form of the future, which is the same as the infinitive with the verb to be. 

or  (*tu* or *ut*) forms the past participle. The simplest mode of forming the imperative is by prefixing the interjections *A!* *Oh!* or *Hai!* to the subject. *Am*, *amma*, *ma*, generally used for the optative, and *akhi*, equally used for the imperative, and the prepositions   (*ar*, *r*), placed after the verb and before the subject, have the same force. The regular form of the subjunctive is hardly distinguishable from the infinitive; it has the preposition  (*n*) prefixed to the verb, and is only determined by the context. The optative mood is formed by prefixing    (*mai*). The infinitive is often given by the verbal root alone, but generally by placing the root of one verb before another, with occasionally the preposition  (*r*). A kind of gerund or participle is formed by prefixing  (*m*), or by  (*her*), in the act of, about, or  (*r*), to, in. The participle is formed by affixing the verbal root to the subject instead of prefixing it, and can be declined by adding the usual terminations; it can also be formed by prefixing   (*ut*), or by affixing    (*ma*), the homophones of *ta*, as    (*mert*), loved. The passive voice is conjugated the same as the active, but giving the verbal root the form of the past participle before the affix pronouns. The forms of *tau* or *ra* are supposed to be prefixed to verbs to give them an impulsive or causative sense, which is also effected by prefixing  or  (*s*) to nouns and verbs. The prepositions are either simple or compound. The former generally consist of one phonetic character or group; the latter of a preposition united with a noun. Both classes are prefixed to their objects, which include also verbs and sentences. , , and  (*n*) are used at different periods for the genitive, dative, and ablative cases; they have the sense of by and to;  or  (*an*) indicates by means of;  (*m*) and its homophones convey the meaning of in the condition of, as, in, for, throughout, by means of, to, from, with;  (*r*), to, for, with, by, from, over, in, as far as, as, &c., and, after an adjective, than;  (*her*), or its fuller form  , signifies by means of, for, in favor of, against, beyond, in the moment of, and by;   (*kar*), stands for under, at the time of, to, at, for, and with. The compound prepositions are sometimes followed by the prefix form of the genitive. Adverbs of negation are always placed before the verb or adjective to which they belong.

 (*nen*), not, and  or  (*nent*), are the principal forms of negation, combined with *put* or *sep*; they signify never.

 (*m*) is used as a prohibitive negative.

Conjunctions are often omitted;  (*hua*),

and,  (*mak*), because, and 

(*khetf*), when, are those chiefly used. Prepositions put before the verb have also the force of conjunctions:  (*en*) or  (*an*), for

that;  (*em*), inasmuch, &c. The syntax consists chiefly in making the sentences short, rarely exceeding ten words; making the verb agree with the subject in number, but putting the verbal root, if alone, always in the singular; prefixing prepositions and interjections to the noun or verb which they govern; and putting the adverb last. The sentence consists often of two antithetical members, in which a substitution of different pronouns frequently occurs, transitions being abruptly made from different persons among themselves. The following is a portion of an inscription found in the tomb of Amenis in Beni-Hassan, dating from the 12th dynasty :

The order both of the columns and the hieroglyphs is from left to right. Verbally translated it reads as follows:

1. <i>nuk</i>	<i>neb</i>	<i>aamt</i>		
I am	a lord	excellent		
2. <i>uah</i>	<i>mert</i>	<i>heka</i>		
very	beloved	ruler		
3. <i>mer</i>	<i>tamaf</i>	<i>arna</i>	<i>kar</i>	
loving	his country	passed I	for	
4. <i>renpau</i>	<i>em</i>	<i>heka</i>	<i>em</i>	
years	as the ruler	of		
5. <i>Sah</i>	<i>baku</i>	<i>neb</i>	<i>en</i>	
Sah	the work	all	of	
6. <i>sutna</i>	<i>kheper</i>	<i>em</i>	<i>tuta</i>	
the palace	was done	by	my hand.	

It may be rendered thus: "I was an excellent and very beloved person, a ruler beloved in his district. I passed many years as the ruler of Sah (Speos Artemidos). All the work of the palace was done by my hand."—The history of the recovery of the Egyptian language, of which not only the vocabulary but also the characters were totally unknown, presents a

wonderful process of induction. The earlier Greeks and Romans were so little interested in the speech of other nations, and at the same time such imperfect linguists, that they left no other information concerning the language than that the Egyptians had two or three different kinds of writing, used for different purposes, and that two of them were confined to sacred uses, which is now known to be erroneous. Their other accounts of the Egyptians and their language are with few exceptions entirely wrong. They picked up stories here and there from communicative priests, and these, mixed up without discrimination, passed from one writer to another, no one caring to criticise, compare, or methodize them. The learned men who in the last century turned their attention to Egyptian writing naturally consulted the works of the ancients, and were consequently led astray. With the exception of a single passage in Clemens Alexandrinus, which is so obscure that it lends itself to many interpretations, all the ancients agreed in speaking of the hieroglyphic system as ideographic. They even gave the meaning of a few signs which are common in the inscriptions, and seemed to be well informed as to their interpretation. As the hieratic and demotic character appeared more cursive, and better suited to the transcription of long documents, they maintained that by means of them the same language was written in letters representing sounds. The writings of Kircher during the 17th, and of De Guignes and Koch during the 18th century, and later those of Zoëga, were based on the opinions of the Greeks and Romans, and failed consequently to throw light on the language. It happened that in 1799 a French engineer officer, M. Broussard, throwing up earthworks at Rosetta (Rashid), discovered a large black slab of stone, somewhat mutilated, with an inscription in hieroglyphics, in demotic, and in Greek. The victory of the English a few days later threw it into the hands of the ambassador Sir William Hamilton, who deposited it in the British museum. By this accident a text was discovered, of which the Greek version stated that it was an ascription of divine honors to one of the Ptolemies, and that the hieroglyphic and demotic versions were transcriptions of the Greek text. Though the sense of a hieroglyphic inscription was thus ascertained, the difficulty remained of determining the value and sound of each character. It was observed that at about the place corresponding to the name of Ptolemy in the Greek version, there was in the hieroglyphic inscription an oval ring enclosing a group of characters; and as a long series of sitting figures on the temple of Karnak had also such rings placed over them, apparently indicating their names or titles, it was conjectured that this ring was the sign of the proper name. An amusing account of the false conjectures made in deciphering this celebrated

inscription, based on the assumption of the Greeks that the hieroglyphic signs were purely ideographic, is given by Birch in Wilkinson's "Egyptians under the Pharaohs." The great discovery that the character was a mixed one, containing partly pictures of objects and partly signs of sounds, was announced by Champollion in a paper read at Grenoble in 1810, and soon after by Thomas Young. Champollion acknowledged that he was led to the discovery by the labors of De Sacy and Akerblad, who had shown that the Greek proper names on the Rosetta stone were transcribed phonetically in the demotic version. These results were obtained by guessing that a group occurring in almost every line was the conjunction; and that a group repeated 29 times in the demotic version corresponded to king in the Greek, where this word occurred about the same number of times; and for the words Alexander and Alexandria in the 4th and 17th lines of the Greek, were discovered two groups of equally close resemblance in the 2d and 10th lines of the demotic. Young's most important contribution was to assert the ideographic nature of many demotic signs, in opposition to the current belief that hieratic and demotic writing were entirely phonetic. It was thereupon observed that the hieratic and demotic characters were abbreviations of the fuller pictures; and Brugsch, now the highest authority on the language, shows in his *Grammaire démotique* that demotic contains at least as many ideographic signs as hieratic writing. All these conjectures were at first applied only to the characters inside the rings. But there remained the difficulty of determining the order in which the characters were written, which might be, as in Hebrew, from right to left, or, as in modern systems, from left to right. This point was soon settled by Champollion. Mr. Bankes brought a little obelisk found in the island of Philæ, which was inscribed with a dedication in Hebrew and Greek to a Ptolemy and his sister Cleopatra. This

inscription was copied by Cailliaud in 1816, and commented on by Letronne and Champollion in the French scientific journals in 1822. Figs. 1 and 2 are the hieroglyphs for

FIG. 1.—Cleopatra.

FIG. 2.—Ptolemy.

Cleopatra and Ptolemy. There was a ring identical with the ring for Ptolemy in the Rosetta stone, and another for Cleopatra. By a fortunate coincidence these names have several letters in common. Assuming from the analogy of other systems that the objects depicted signified the initial letter of their Coptic names, both groups were spelled out, and Champollion was in possession of 11 phonetic signs of the old Egyptian lan-

guage. It now became plain that in this case the signs were not syllabic, but alphabetic. Applying them to monuments which appeared to be of the Roman epoch, and attempting to decipher the royal rings upon them, Champollion found an almost complete list of the Roman emperors, each with his title, emperor, added, and this title became a clue to all similar inscriptions. Some of the opponents of Champollion suggested that the hieroglyphs were only used phonetically in order to transcribe the names of the foreign lords of Egypt; but further researches proved that well known old Egyptian kings, as Psammetichus, Shishak, and Rameses, had their names written in phonetic characters also. These discoveries made it certain that the hieroglyphic inscriptions could only be read by ascertaining the sounds of the old Egyptian language; if the writing were pictorial or symbolical, the sense could have been discovered without knowing a single sound. To discover the sounds, several learned men turned to the modern Egyptian or Coptic language, which was expressly stated by early Christian fathers to be almost the same as the demotic, though written in a different alphabet. Though the Coptic language was almost extinct, there was a school of Coptic priests at Rome during the last century, who could still speak the language of their sacred books; and from the information they possessed, together with the Coptic version of the Scriptures, a very good knowledge not only of the grammar but also of the vocabulary had been obtained. Champollion made himself master of the Coptic language, and saw that it retained more or less accurately the old Egyptian names of a large number of objects. He further analyzed grammatical forms, terminations, and inflections, and found the same close correspondence. When he was sent to Egypt to explore the ruins in person, he applied what letters he knew to groups of hieroglyphics, apparently giving the names of numerous pictures of well known objects, engraved in the tombs of Beni Hassan, and found that the Coptic furnished in almost every case a direct clue to the sound of the hieroglyphs. He thereupon easily completed his alphabet from partially read words, agreeing in sense with known names; and so the great discovery was gradually completed, sounds suggesting signs, and signs sounds, each new step verifying and correcting previous inferences as well as suggesting new ones. Two difficulties impeded the progress of the discovery. The first was to understand the proper application of the symbolical hieroglyphs, and when the same sign was to be used in the ideographic and when in the phonetic sense. Champollion concluded that the written system of 1,000 signs, used at random ideographically or phonetically, must have been a source of confusion to the Egyptians themselves, and that they must have used some means to avoid it. He therefore looked for and found indications added to the pictures, informing the

reader how to understand them. But there are some specimens of a sort of writing which Champollion left unexplained, and which he considered symbols used by the priests as a really secret character. This view has been supported by De Rougé and Lauth, but has been denied by Dümichen, who says he has been unable to find in the monuments any systematic secret writing, side by side with the usual hieroglyphics. Birch agrees with this view, and advances the theory that the 22d dynasty, of Assyrian origin, introduced phonetic signs for many ideographs, and so produced these so-called anaglyphs. Brugsch considers them merely a profusion of licenses and individual fancies, which make the interpretation a matter of great labor and ingenuity, but not impossible. The second obstacle, though greater, was readily overcome. It soon became evident that the Egyptians used different signs to signify the same sound. At the outset, when the names *Berenike* and *Aleksandros* were guessed at, it was found that there were different signs for *k* and for *s*. On comparing the several copies in the European museums of the long and elaborate book of ritual which the old Egyptians placed beside mummies in the coffin, it was found that, though they are identical in sense and character, they contain frequent variations as to single signs, and that in hieratic copies the same sign generally represents these varieties. It was clear that these were different equivalents for the same sounds, or what are called homophones. After the discovery of one of them the rest became quickly known. Lepsius has since established that the most ancient alphabet admitted very few homophones, and De Rougé says that many of them really indicate slight variations of pronunciation, which, like the various sounds of *th*, were carefully distinguished by some scribes by separate signs. After the discovery of the homophones it only required additional researches to complete the structure of which Champollion had laid the foundation and sketched the plan. Hundreds of perfectly distinct documents have since been read by the received principles of interpretation, and a consistent meaning extracted from them. Though no other corroboration was wanting, it came crowding upon the Egyptologists in the numerous confirmations of historical facts thus deciphered. Lepsius found in 1866, while making researches at Tanis, another trilingual inscription in hieroglyphics, demotic, and Greek; and the Egyptian, according to Birch, was read off and explained much easier than a fair Latin scholar could have rendered the same amount of Tacitus, and the translation produced a sense identical with the Greek version. Another test of the correctness of the principles of interpretation laid down by modern Egyptologists was offered a few years ago by Mariette, who copied from the pillars along the line of the Suez canal inscriptions set up in four languages by Darius I.,

king of Persia, describing how he had undertaken the cutting of the canal, but stopped it when almost completed because he was persuaded that the levels of the Red sea and the Mediterranean varied, and that Egypt would be inundated by opening the canal. The inscription found on several stone pillars was written in hieroglyphics and in the three kinds of cuneiform characters, and it was found that the Persian and Assyrian versions correspond in sense to the hieroglyphic as now interpreted, adding, however, many details intended for the special edification of the Egyptian subjects of the great king. Champollion's system of interpreting hieroglyphics encountered great opposition at every step of his discovery. Among his most prominent opponents were Klaproth, Palin, Janelli, Williams, Secchi, Seyffarth, and Uhlemann, every one of whom proposed some method of decipherment as much at variance with the methods of the others as with Champollion's; with the exception of Uhlemann, who adopted Seyffarth's suggestions. The chief value of their writings consisted in stimulating new researches to correct or establish the rules laid down by Champollion and his followers. The most eminent among these are Sylvestre de Sacy, Niebuhr, Humboldt, Lepsius, Bunsen, Rosellini, Leemans, Wilkinson, Hincks, Brugsch, Birch, De Rougé, Chabas, Le Page Renouf, Lauth, Dümichen, Goodwin, Czermak, Devéria, Eisenlohr, Ebers, Mariette, and Maspero. The researches on the hieratic writing were of necessity closely linked to the study of hieroglyphics. The decipherment of the demotic writing was specially studied by De Sacy, Akerblad, and Young. It was further elucidated by Champollion, Tattam, Salvini, Lepsius, De Sauley, Leemans, and Maspero, and was finally treated by Brugsch in a separate grammar and a hieroglyphic-demotic dictionary.—LITERATURE. The literature of Egypt presents a remarkable exception to the literatures of other countries. It contains no signs of a gradual development of different species of composition at different epochs. The characters were changed, and the language underwent some modifications, but the literature remained in its principal features the same. Novels or works of amusement predominated in the great epoch of the Rameses, and historical accounts of Egypt under the Ptolemies, just as homilies, church rituals, and other Christian literature invaded Egyptian in its Coptic stage; but the same type and general style appear in every epoch. There is therefore no need of a chronological sketch of Egyptian literature. Its materials are scanty, and many periods of Egyptian history are as yet complete literary blanks. Another misfortune is that even the scanty documents recently obtained are not all accessible; many of them are lying unread in private collections. The magnificent collections of Mr. Harris of Alexandria, and of Mr. Smith, an American resident at Luxor, and doubtless many others,

are yet almost entirely unknown.—The religious is the most important branch of the Egyptian literature that has come down to us. At first sight it seems to proclaim the Egyptians the most polytheistic of men, but a more careful examination leads to the supposition that the various gods were only intended to bring out in symbol and in allegory the various qualities and manifestations of one great God, uncreate, eternal, and omnipotent. Egyptologists strongly combat the commonly received opinion that the doctrine of one God was the belief of the learned only, and that the Egyptian ritual was intended for the vulgar. The most prominent of the theological treatises is the "Book of the Dead," also called the "Funeral Ritual." The earliest known copy is in hieratic writing of the oldest type, and was found in the tomb of a queen of the 11th dynasty, which can hardly be placed later than 3000 B. C. The sense of certain chapters had already become obscure to the writers, who add many notes and rubrics, and sometimes another reading; thus it contains another version of the 64th chapter, ascribed to King Menkera of the 4th dynasty. The latest copy is of the 2d century A. D., and is a demotic papyrus written in pure Coptic. It consists, in its complete state, of 166 chapters, many of which were added in the days of the new empire, or about 1600 B. C., and perhaps as late as the time of Psammetik. The main body of the work is uniform throughout, and gives a mystical account of the adventures of the soul after death, and directions how by the use of theological knowledge, as being able to recite the names and titles of innumerable gods, the soul could reach the hall of Osiris. Here it was to be judged by Osiris and the 42 assessors, who took cognizance of the 42 mortal sins. It was probably from some confused report of this chapter of the ritual that Diodorus was led to state, what is often repeated in modern books, that the Egyptians held trial over their dead before burial. The soul was sent, after a successful examination, to the abode of the sun, to live in blessedness. Almost every museum in Europe has specimens of the ritual, and many have published facsimiles of it. A complete translation, by Dr. Birch, may be found in the 5th volume of the 2d edition of Bunsen's "Egypt's Place in Universal History" (London, 1867). The best editions of the whole text are Lepsius's *Todtenbuch* (Leipsic, 1842), from a Turin copy in linear hieroglyphics; De Rougé's *Rituel funéraire* (Paris, 1861-'5), in hieratic; and a collection of the most important texts in Lepsius's *Älteste Texte des altägyptischen Todtenbuchs* (Berlin, 1867). The preparation of these books of the dead seems to have been a regular trade with the Egyptian priests. They were written and illustrated in various styles, proportioned to the rank of the deceased or to the price which his relatives chose to pay, and they were placed in the coffin with the dead. As the books were to be sealed up, and

not to be read, or seen again by the relatives, they are often written with the greatest carelessness, and are full of omissions and gross faults in orthography. They seem to have been kept ready made, for the name of the deceased appears in different ink and handwriting from the rest of the book, and appears to have been inserted in a blank left for the purpose. The only other kind of composition which can be strictly classed as theological are the treatises describing the metamorphoses of the gods, and the lamentations of Isis, found in the tombs of priests and priestesses; but these books are so replete with allegories that it is almost impossible to discover their meaning. To this class belong also the myths in the Ptolemaic temples, and it is believed that when the immense profusion of pictures found at Edfoo, Esne, Denderah, and other such temples are collected and deciphered, the obscurities of the ritual will be greatly diminished. They explain such myths as that of the winged disk, or the adventures of Horus in avenging his father Osiris, and possess occasional historical allusions of great value. Some of these texts are given in Brugsch's *Die geflügelte Sonnenscheibe* (Berlin, 1870), and Naville's *Textes relatifs au mythe d'Horus* (Paris, 1870). The devotional treatises mainly consist of hymns, some of which are addressed to the sun or to the god of Egypt considered as such, and abound in lofty and pure sentiment. Translations of such hymns are scattered among the archaeological, philological, and oriental reviews; some may be found in Chabas's *Papyrus magique Harris* (Châlons, 1861) and Maspero's *Hymne au Nîle* (Paris, 1868). The ethical treatises are in part in the form of regular moral essays, either in a connected discourse or in disjointed proverbs; partly in an epistolary form, under the garb of a private letter from a teacher to his pupil, but evidently intended for general use; and also in the form of dialogue. The oldest hieratic book which we possess is the moral treatise of Prince Ptah-hotep, and the copy of it, called the *Prisse papyrus*, may have been prepared as late as the 11th dynasty; but the author speaks of having reached a ripe old age under Assa, the last king but one of the 5th dynasty. The collection of proverbs in the Leyden papyri, which is of the Ramesid era, and the instructions of a demotic papyrus in the Paris library, dating from the Ptolemies, differ in no fundamental point from the ancient treatise, and do not even show a development. They enumerate and enjoin the same private and social qualities which are now thought to make a man respectable. Fragments of Ptah-hotep's moral discourse have been translated by Dümichen in *Der Aegyptische Felsentempel von Abu-Simbel* (Berlin, 1869), and by Lauth in his *Moses der Ebräer* (Munich, 1868). The proverbial precepts of the demotic treatises are given in the *Recueil de travaux relatifs à la philologie égyptienne et assyrienne* (Paris, 1870). The moral philosophy of one of the Leyden papyri speaks in para-

bles, and explains its truths by the aid of metaphors from common life. A translation of it is given in Leemans's *Monuments du musée d'antiquités des Pays-Bas* (Leyden, 1839-'64). The instructions conveyed in letters mostly concern particular cases, and recommend special professions; and being all the compositions of literary men, they naturally laud their own occupation as the highest. The Sallier papyri in the British museum furnish the best specimens of these epistolary treatises. There are translations of them by Prof. Goodwin in the "Cambridge Essays" for 1858.—The magical literature has come down to us in many specimens. They are preserved in the papyrus of Mr. Harris, which Chabas has translated, and in the Ramesid papyri and demotic fragments of the Leyden and Paris museums. The principles adopted in the magic ceremonies of the Egyptians were uniform. There is first a mention of a mythological event, generally relating to some of the conflicts between Osiris and Set, or the good and evil powers in nature; secondly, the conjurer identifies himself with a deity whose powers and attributes he assumes by means of incantation; lastly, injunctions and threats against the objects to be conjured. People in almost every condition of life appear to have sought assistance from magic, and numerous little rolls of papyrus inscribed with magic formulas have been found, which were used as amulets to protect the wearer from sickness or death.—The medical papyri, or prescriptions of the old Egyptians, are described by Brugsch in his *Ueber die medizinischen Kenntnisse der alten Aegypter* (1853), and in his *Notice raisonnée d'un traité médical*, &c. (Leipsic, 1863), reprinted from the second volume of his *Recueil de monuments* (Leipsic, 1859); by Chabas in his *Mélanges égyptologiques* (vol. i.); and by Birch in Lepsius's *Zeitschrift* for 1871. The most remarkable is the papyrus of Berlin, which states that it was discovered rolled up in a case, under the feet of an Anubis in the town of Sekhem, in the days of Tet (or Thoth), after whose death it was transmitted to King Sent, and was then restored to the feet of the statue. King Sent belonged to the 2d dynasty, and if the treatise was old in his day, Manetho's statement that the second king of Egypt, the successor of Menes, composed works on anatomy, is more than probable. These data remove the origin of medicine among the Egyptians to a time long previous to 3000 B. C. The contents of this papyrus give a kind of anatomy of the human body, and a number of remedies, which were generally to be taken internally, and consisted of carefully proportioned prescriptions, in which the milk of various animals, honey, salt, and vinegar play a prominent part. There are also directions for the application of raw flesh, lard, and ammonia, and prescriptions of draughts, unguents, and injections. Noticeable is the entire absence of charms and superstitious observances in administering medicines,

and the attempts at rational treatment far surpass the medical literature of the early Greeks. Later documents are of inferior scientific value, and they contain a great deal of magic and incantation, although the remedies are prescribed for the most part separately from them. But the documents are so few that we may have recovered accidentally a higher order of treatise from the earlier, and inferior kinds from the later period of Egyptian history. The demotic papyrus repeats the same technical terms for remedies, but shows a small proportion of honest prescriptions; and love philtres, which turn the love of women toward their husbands and lovers, and not the opposite, as generally told by classical authors, play a great part in it. The Coptic period furnishes a fragment treating of skin diseases, one of the most prevalent and permanent plagues of Egypt. It is a small portion of a large work, as the prescriptions preserved are called the 185th chapter; they consist of potions, baths, and unguents.—The scientific treatises show, especially in a document belonging to the old empire, and now preserved in the Berlin museum, that the Egyptians were acquainted with the true motion of the planets, including that of the earth. Among the Rhind papyri in the British museum, there is one called the geometric papyrus, of which Mr. Birch has published a short description in Lepsius's *Zeitschrift* for 1868. The age is given as the 20th dynasty, or about 1100 B. C. The treatise proceeds in regular propositions, stating the questions with "Suppose," and the answers with "Therefore" or "It follows." It is chiefly concerned with mensuration, the measuring of fields, and the estimating of the solid contents of pyramids; its title reads, "Principle of arriving at the Knowledge of Quantities, and of solving all Secrets which are in the Nature of Things." The area to be measured is divided into parallelograms or isosceles triangles, and the lengths of the sides are generally given in the statement of the question.—Epistolary correspondence is, like the solar hymns, one of the best known and most perfectly understood branches of Egyptian literature. From the Ramesid era, which was undoubtedly the most literary of all, we have about 80 letters on various subjects, from different scribes, of whom the names of 13 are preserved, and they are mere specimens of style and illustrations of manners. There are about 20 letters in different papyri of the Leyden collection, but as some of them seem to have been prepared for transmission, they cannot well be considered as specimens of literature. The most important collection is that in the Sallier and Anastasi papyri of the British museum, and consists of 58 letters, of which a few are duplicates. The collection was made by three scribes, about the time of the Exodus, and their names are Pentaür, Pinebsa, and Enna.—The fictitious writing of the ancient Egyptians is represented by two valuable and tolerably com-

plete relics: "The Tale of the Two Brothers," contained in the document known as the D'Orbigny papyrus of the British museum, and first described by De Rougé, and "The Romance of Setna," recently discovered in the tomb of a Coptic monk by Brugsch, who furnished a translation of it in the *Revue archéologique* for 1867. The former was written by the scribe Enna, and evidently intended for the amusement or instruction of one of the royal princes, whose name is mentioned in the last chapter. One of the most striking features of this romance is the low moral tone of the women introduced, and the blunt realism exhibited in their life and language. Other documents of the same period show that the Egyptian ladies held a far higher position than is here implied. Our demotic copy of the "Romance of Setna" was written in the 2d or 3d century B. C. The story turns upon the danger of acquiring possession of the sacred books without a clear right and great precaution; but the opening of the story and its date and superscription are missing. The epics and biographical sketches, excluding here the sepulchral monuments, which are of greater value to history than to literature, consist of a number of narrations of personal adventure in war or travel, and are distinguished by special efforts at the graces of style. Prominent among them is the epic of Pentaur, on the achievements of Rameses II. in his war against the Kheta. This poem, which has been called the Egyptian Iliad, was very popular and widely known, and several copies of it are in existence. Considering that it is several centuries older than the Greek Iliad, it deserves admiration for the rapid narration of the antecedents and consequences of the great scene in order to preserve it as the most prominent and central picture of the poem. Translations of it are given by Prof. Goodwin in the "Cambridge Essays," and by De Rougé in the *Recueil de travaux relatifs à la philologie égyptienne*. The biographical sketch of Mohar has been called the Odyssey, by way of contrast with the preceding. The author gives an account of the journey of Mohar, evidently a high official, through Syria and Palestine, gathered from the correspondence or diary which the latter had sent to him. This papyrus, in the Anastasi collection of the British museum, has been translated by Chabas, under the title of *Voyage d'un Égyptien* (Berlin, 1866), by Goodwin, and by Lauth in the appendix of his book *Moses der Ébräer*; and the last named author endeavors to establish that the person spoken of in the document was Moses himself, while Brugsch and De Rougé believe that the journey is not real, but only intended to furnish an entertaining description of the lands spoken of. The satirical writings and beast fables of the Egyptians caricature the foibles of all classes, and do not even spare the sacred person of the king. They are often illustrated with satirical pictures in mimicry of the Pharaohs and their

courts. One such, known as the satirical papyrus of Turin, has been published with the caricatures in Lepsius's *Auswahl*. — Besides these numerous specimens of a strictly literary nature, a large amount of judicial documents, as petitions, processes at law, judgments, decrees, and treaties, has also been recovered. In the chronological documents, history is computed after the manner of early nations by a list of kings and priests; and without dwelling upon their historical value, we owe to them the whole of our knowledge of the Egyptian language, as the decipherment of some proper names mentioned in them furnished the first clue to the reading of hieroglyphics.

EHNINGER, John Whetton, an American artist, born in New York, July 22, 1827. He graduated at Columbia college in 1847, and in 1848-'9 he was a pupil of Couture in Paris. His first oil painting, "Peter Stuyvesant" (1850), the subject of which was taken from "Knickerbocker's History of New York," was engraved by the American art union. Among his best works are "Love me, love my Horse," "The Sword," "The Foray," the landscape of which is by Mignot, "Lady Jane Grey," and *Ars Celare Artem*. He has also produced a series of etchings illustrating Hood's "Bridge of Sighs," published in 1849, another on subjects from Irving's story of "Dolph Heyliger" (1850), eight illustrations of Longfellow's "Miles Standish" (1858), and various other works of the kind.

EHRENBERG, Christian Gottfried, a German naturalist, born April 19, 1795, died June 27, 1876. He was educated at Leipsic and Berlin. In 1818 he published *Sylva Mycologica Berolinenses*, in which he described 62 new species of cryptogamous plants. In 1820 he visited Egypt, Nubia, and Arabia, at the expense of the Berlin academy of sciences, and continued his scientific explorations in those countries for six years. On his return to Berlin he was appointed extraordinary professor of medicine. In 1829 he accompanied Humboldt to the Ural mountains and central Asia. In 1842 he was elected permanent secretary of the academy, and in 1847 was appointed to a regular professorship. The scientific results of his observations in Africa are contained in *Symbolæ physica Mammalium, Avium, Insectorum et Animalium Evertibratorum* (Berlin, 1828-'33); *Die Korallenthierie des Rothen Meeres* (1834); and *Die Akalephen des Rothen Meeres* (1836). He engaged in the investigation of infusoria, and arrived at results of the greatest value, which were presented in various publications, the most complete of which is *Die Infusionsthierehen als vollkommene Organismen* (with 64 plates, Leipsic, 1838). He discovered fossil infusoria, showed the similarity of their phenomena in different parts of the world, and published on this subject *Die fossilen Infusorien und die lebendige Dammerde* (1837); *Die Bildung des europäischen, libyschen und uralischen Kreidefelsens und Kreidemergels aus*

mikroskopischen Organismen (1839); and especially *Mikrogeologie* (1854). For some account of his discoveries and classification, see ANIMALOULES. Among his works on other subjects is *Ueber die naturwissenschaftlich und medicinisch völlig unbegründete Furcht vor körperlicher Entkräftung der Völker durch die fortschreitende Geistesentwicklung* (Berlin, 1842). His latest publication is *Mikrogeologische Studien als Zusammenfassung seiner Beobachtungen des kleinsten Lebens der Meerestiefgründe aller Zonen und über dessen geologischen Einfluss* (Berlin, 1872).

EHRENBREITSTEIN (*i. e.*, the broad stone of honor), a town of Prussia, on the right bank of the Rhine, opposite Coblenz, with which it is connected by bridges; pop. in 1871, 2,504, exclusive of the garrison. It is situated at the foot of a rocky height, upon which is the fortress. The fortress of Ehrenbreitstein was probably founded by the Romans under the

EIBENSTOCK, a town of Saxony, near the right bank of the Mulde, 16 m. S. E. of Zwickau; pop. in 1871, 6,362. It has manufactories of muslin, lace, chemicals, and tobacco; and in the vicinity are several tin mines, to which the town owed its foundation in the 12th century.

EICHENDORFF, Joseph Karl Benedict, baron, a German author, born near Ratibor, Upper Silesia, Dec. 10, 1788, died at Neisse, Nov. 26, 1857. He fought as a volunteer in the last campaigns against Napoleon I., and held various offices under the Prussian government, retiring in 1844. He was a representative of the romantic school, wrote many fine poems, novels, and plays, and translated Don Juan Manuel's *El conde de Lucanor* (Berlin, 1824) and Calderon's religious plays (2 vols., Stuttgart, 1846-'55). Among his critico-historical writings are *Der deutsche Roman des 18. Jahrhunderts in seinem Verhältnisse zum Christenthum*

(1851), and *Geschichte der poetischen Literatur Deutschlands* (1856). The 4th edition of his poetry and of his most popular novel, *Aus dem Leben eines Taugenichts*, appeared in Berlin in 1856.

EICHHORN, Johann Gottfried, a German scholar, born at Dörenzimmern, in the principality of Hohenlohe-Oehringen, Oct. 16, 1752, died in Göttingen, June 25, 1827. He studied theology at Göttingen, in 1775 was elected professor of oriental languages in the university of Jena, and in 1788 was called to the same

office at Göttingen, where he taught till near his death. He first proved the extent of his learning by treatises on the commerce of the East Indies prior to the time of Mohammed, and on the ancient history of the Arabs. At Göttingen he devoted himself especially to Biblical criticism, and published *Repertorium für biblische und morgenländische Literatur* (18 vols., Leipsic, 1777-'86), and the *Allgemeine Bibliothek der biblischen Literatur* (10 vols., 1787-1801), which he prepared in connection with other learned men. He was especially influential in founding the interpretation of the Scriptures on a knowledge of Biblical antiquity and oriental modes of thought by his introductions to the Old and New Testaments, and his works on the Hebrew prophets and on the Apocalypse, besides many valuable papers in periodical works. Having conceived the plan of a full history of all branches of intellectual culture in Europe since the revival of letters, he associated him-

Ehrenbreitstein.

emperor Julian, was rebuilt in the 12th century by Hermann, archbishop of Treves, and became of great strategic importance during the thirty years' war. The French under Marshal Boufflers, aided by Vauban, in vain besieged it in 1688. They assailed it again at the end of the following century, but gained possession of it (January, 1799) only after a siege of 14 months, and after reducing the garrison to starvation. In 1801 they blew up its defences, but the fortress was subsequently rebuilt by Prussia. The works will lodge 100,000 men, yet a garrison of 5,000 is deemed sufficient to defend them. The magazines are capable of containing provisions for 8,000 men for ten years. The escarped rocks and steep slopes on three sides of the fortress seem impregnable. The platform on the top of the rock serves as a parade ground, and covers vast arched cisterns capable of holding a three years' supply of water, which is obtained from springs without the walls.

self with several scholars, and composed, as an introduction, the *Geschichte der Literatur von ihrem Anfange bis auf die neuesten Zeiten* (6 vols., Göttingen, 1805-'12). Among his other writings are *Urgeschichte* (edited by Gabler, 2 vols., 1790-'93), in which he examined the Mosaic records of the creation and fall; and works on the French revolution (1797), on ancient history (2 vols., 1811-'13), and on the history of the last three centuries (6 vols., 3d ed., 1817-'18).—His son KARL FRIEDRICH, born Nov. 20, 1781, professor of law at Berlin and elsewhere, Prussian state councillor, &c., was the author of works on German law and history, and edited with Savigny and others from 1815 to 1838 the *Zeitschrift für geschichtliche Rechtswissenschaft*. He died July 4, 1854.

EICHSTÄDT, a town of Bavaria, on the river Altmühl, 56 m. N. N. W. of Munich; pop. in 1871, 7,011. It is the seat of a bishop and has several schools and hospitals. Its manufactures are chiefly woollen and cotton fabrics, iron and stone ware, and beer. The most remarkable public buildings are the castle, the council house, and the cathedral, a fine Gothic edifice. The castle of Wilibaldsburg, which overlooks the town from a height of 1,200 ft., was formerly the residence of the bishops, and is now used for barracks.—Eichstädt was founded by the Anglo-Saxon St. Wilibald, created bishop about 745, whose statue is in one of the public squares. It increased in size through the pilgrimages made to the shrine of St. Walpurgis, whose remains were deposited there in 871, and whose church is still visited annually by thousands of pilgrims. Upon the death of Count Hirschberg, in 1305, the bishopric was endowed with his estates, and afterward it became one of the richest foundations of Germany. It was secularized in 1802, and erected into a principality, and in 1805 was incorporated into Bavaria. The principality was in 1817 assigned with other territory to Eugene Beauharnais, duke of Leuchtenberg. It ceased to be a principality in 1854. The present bishopric of Eichstädt is under the jurisdiction of the archbishop of Bamberg.

EICHWALD, Karl Eduard, a Russian naturalist, born at Mitau, July 4, 1795, died in November, 1876. He studied at Berlin, travelled several years, in 1823 was appointed professor of zoology and midwifery at Kazan, in 1827 of zoology and comparative anatomy at Wilna, and in 1838 of mineralogy and zoology at St. Petersburg, and retired in 1851. From 1825 to 1827 he explored the Caspian sea and the Caucasus. In 1846 he made scientific excursions in the Tyrol, Italy, Sicily, and Algeria. He also made geological journeys through France, Switzerland, parts of Russia, and the Scandinavian countries. His numerous works, written in Latin, German, French, and Russian, relate chiefly to the botany, natural history, geology, mineralogy, and palæontology of Russia.

EIDER, a river of northern Germany, rising near Kiel, and flowing into the North sea not

far from Tönning. Its general course is W., and for a considerable distance it forms the boundary between Schleswig and Holstein. Its length is about 105 m., of which 70 are navigable. With the aid of a canal from Rendsburg to Kiel fiord, this river forms a communication between the North and Baltic seas.

EIDER DUCK (*somateria mollissima*, Leach), one of the *fuligulæ* or sea ducks, well known for the remarkable softness of its down and the beauty of its plumage, and common, like other arctic species, to both hemispheres. The bill is elevated at the base, compressed behind the nostrils, divided in front by an acute angle of feathers, flattened at the tip, which is armed with a strong, broad, and hooked nail; the lamellæ are moderate and far apart; the wings are moderate, pointed, the first and second quills longest; the tail short and wedge-shaped; tarsi more than half as long as the middle toe; the toes long, united by a full web. The head is very large, the neck short,

Eider Ducks (*Somateria mollissima*), Male and Female.

the body bulky and much depressed; the feet are short, and placed far behind. The plumage is short, dense, soft, and blended. The bill is pale grayish yellow, iris brown, feet dingy light green with dusky webs; upper part of head bluish black, with the central part white; occiput, upper part of hind neck, and sides of neck delicate pale green; sides of head, throat, and neck white; lower neck and upper breast cream-colored or buff; rest of lower surface black, as are the tail coverts and middle of the rump; rest of upper parts white, the scapulars tinged with yellow, except the secondaries, which are brownish black, and the primaries, grayish brown; the length is 25 in., the extent of wings 42, the tail 4½, bill 2¾; the weight is from 4½ to 5½ lbs., greatest in winter. The female differs greatly from the male, being somewhat smaller, and having the general plumage brown barred with black, lighter on the head and neck; secondaries and their coverts with white tips; the young in the first winter resemble the female. The eider is rarely seen south of New York; east of Boston it

is more and more abundant as the latitude increases. Thousands of pairs breed and pass the summer in Labrador, where they are called sea ducks, a name also given to other species; they there begin to make their nests about the last of May, amid the grass and low bushes, and in sheltered places among the rocks; many nests are found near together, made of seaweed, moss, and twigs, each containing from five to seven eggs, about 3 in. long, of a pale olive green; the eggs are considered great delicacies by the fishermen. When the eggs are laid, the female plucks the down from her breast, and places it under and around them, and when incubation commences the male leaves her to take care of her eggs and herself; when she quits the nest in search of food, she pulls the down over the eggs; she leads the young to the water, or carries them thither in her bill, teaches them to dive for food, and protects them from their worst enemies, the black-backed gulls; by the 1st of August old and young are moving southward. In many places the nests are robbed by man of both down and eggs, when the female seeks another male, and lays a second time with the usual quantity of down; if again disturbed, she will try a third time, the down being supplied from the breast of the male. The unnecessary destruction of the birds by the eggers of Labrador has nearly destroyed the trade, and driven them further north. The down of a nest, though bulky enough to fill a hat, when cleared of grass and twigs rarely weighs more than an ounce, though an instance has been related in which the quantity obtained the first time from a single nest is said to have weighed half a pound; when properly cleaned it is worth from 12s. to 14s. per lb. for the English market. So highly is it prized for warmth and lightness, that in Iceland and Norway the districts resorted to by the duck are valuable property, and are strictly preserved. The Icelanders make artificial islands by cutting off projecting points from the mainland, such spots being more attractive to the birds from their seclusion than the mainland itself. Eiders fly rapidly, steadily, and generally near the water, rarely more than a mile from the shore; they are very expert divers, descending several fathoms, and remaining long under water; their food consists of crustacea, mollusks, and the roe of fishes; the gizzard is large and muscular; they are rarely seen inland, unless driven in by storms. They are shy, and difficult to kill; the flesh of the young and females is said to be well flavored, but that of the males is tough and fishy, and rarely eaten. The common eider has been reared in captivity, becoming as gentle and tame as the domestic duck, with which it readily associates; from its eminently social disposition, it would doubtless be a valuable acquisition in a domesticated state, for its feathers and down, for its eggs, and even for its flesh. —The king eider (*S. spectabilis*, Leach) is handsomer than the preceding, and like it is an

inhabitant of the higher latitudes of both continents. The bill of the male is yellowish, the upper mandible having at the base a soft, compressed, orange-colored substance, extending upon the forehead; the front is covered with short black feathers; the general shape is like that of the common eider, and the character of the plumage the same. The iris is bright yellow, feet dull orange with the webs dusky; the head is bluish gray, darkest behind; the sides of the head pale bluish green; a black spot below the eye, and two lines of the same color on the throat; fore neck cream-colored; the sides and posterior part, with a patch on the wings, and one on each side of the rump, white; lower plumage blackish brown; posterior part of back, scapulars, larger wing coverts, and secondaries brownish black, the latter with a greenish gloss; primaries and tail blackish brown; the size is about that of the other species. The female is quite different,

King Eider Ducks (*Somateria spectabilis*).

having the head grayish yellow, with small brownish black lines, the scapulars with brownish red margins, the general color of the lower parts pale yellowish brown, and the quills and tail deep grayish brown; the feathers of the lower neck, breast, sides, and lower tail coverts with a centre and margin of brownish black. The king eider is not often seen in the United States, breeding further north than the common eider; its habits resemble those of the latter species; its home is the sea, the land being visited only in the breeding season; its down is valuable; the eggs are about 2½ in. long, of a dull greenish color.

EILDON HILLS, a group of hills in Roxburghshire, Scotland, consisting of three conical peaks, the highest of which has an elevation of about 1,350 ft. At their foot on the north is the town of Melrose. From their summits a magnificent view of the romantic border scenery of Scotland may be obtained. There is a tradition among the peasants of the neigh-

boring country that these hills were originally one mountain, which was divided into three separate summits by a demon under the wizard Michael Scott.

EILENBURG, a town of Prussia, in the province of Saxony, 14 m. N. E. of Leipsic, on an island formed by the Mulde; pop. in 1871, 10,135. It has many flourishing manufactures, chiefly of cotton and linen goods, chemicals, and tobacco. It received its name from the ancient castle near it, which is mentioned in the 10th century as a seat of the counts of Ilburg, and as an important frontier fortress against the Wends and Sorbs.

EIMBECK, or **Einbeck**, a town of Prussia, in the province of Hanover, on the Ilme, 21 m. N. N. W. of Göttingen; pop. in 1871, 6,189. It has manufactories of woollens and linens, several bleacheries and tanneries, and a gymnasium founded by Luther. It was formerly the capital of the county of Mansfeld, and was once prominent among the military towns of the empire, but the French destroyed its walls in 1761.

EINSIEDELN, or **Einsiedlen**, a village of Switzerland, in the canton of Schwytz, on the Sihl, 20 m. S. E. of Zürich; pop. in 1870, 7,633. It

is about 3,000 ft. above the sea. Adjoining the village is a famous Benedictine abbey whence it derives its name, founded about 900, at the spot where St. Meinrad was murdered, but several times rebuilt. The present edifice, which dates from 1719, is in the modern Italian style, and contains a museum, a library of 30,000 volumes, and a marble chapel wherein is an image of the Virgin that attracts multitudes of Roman Catholics from many parts of Europe. The average number of communicants, chiefly from Switzerland, Germany, and Italy, annually exceeds 150,000. The yearly festival is held on Sept. 14; and in 1861 the thousandth anniversary of the death of St. Meinrad was celebrated with great pomp. Connected with the abbey are an ecclesiastical seminary, a gymnasium, and a lyceum.

EISENACH, a town of Germany, in the grand duchy of Saxe-Weimar, formerly capital of the principality of Saxe-Eisenach, 45 m. W. of Weimar; pop. in 1871, 13,967. It is situated on the border of the Thuringian forest, at the confluence of the Hösle with the Nesse, 712 ft. above the sea, and is the chief station on the Thuringian-Saxon railway. The town is enclosed by a wall, has broad streets generally paved with

The Wartburg, Eisenach.

basalt, and several remarkable public buildings, among which is the castle, formerly the residence of the princes of Eisenach. Its manufactures are chiefly woollen and cotton fabrics, white lead, and pipe heads of soap stone. In its environs on a lofty height is the ancient castle of Wartburg, once the residence of the land-graves of Thuringia, celebrated as the place where the minnesingers contended for the palm of poetry, and as the asylum where Luther composed his translation of the Bible. The "Evangelical church conferences," consisting of repre-

sentatives of all the governments of Germany and of Austria, for the regulation of the Protestant church affairs of these states, have been held here biennially since 1852.—The ancient principality of Eisenach was in 1440 united with Saxony. Three times, in 1596, 1640, and 1672, a special line of Saxe-Eisenach was founded, but each of them was of short duration; the last became extinct in 1741, when the country was united permanently with Saxe-Weimar.

EISENBERG, a town of Germany, in the duchy of Saxe-Altenburg, on an affluent of the

Elster, 40 m. S. W. of Leipsic; pop. in 1871, 5,261. It has a Protestant lyceum, an observatory, and manufactories of china ware and woolen goods. An important trade is carried on in lumber. The ducal castle, Christiansburg, has a beautiful church in Italian style, built from 1676 to 1692. In 1675 Eisenberg became the capital of the new sovereign duchy of Saxe-Eisenberg, which became extinct on the death of its founder, Duke Christian.

EISENBURG, a county of Hungary. See VAS.

EISENLOHR, *Wilhelm Friedrich*, a German physicist, born at Pforzheim, Jan. 1, 1799, died in Karlsruhe, July 9, 1872. He studied at Heidelberg, and in 1819 was appointed teacher of mathematical and physical sciences at the lyceum of Mannheim, where he remained till 1840. From that date till 1865 he was professor in the polytechnic institute at Karlsruhe. His principal work is *Lehrbuch der Physik* (1836; 10th edition, 1872).

EISENSTADT (Hun. *Kis-Márton*), a town of Hungary, on the slope of the Leitha hills, near the frontier of Lower Austria, 11 m. N. W. of Oedenburg; pop. about 3,000. It consists of the town proper, surrounded by walls, and of the Schlossberg, which formerly belonged to the Esterházy family, and contains a magnificent palace with pleasure grounds, a theatre, and a chapel. The library is rich in church music, masses, and oratorios, and contains some of Haydn's MSS. In a church for pilgrims on a so-called Calvary mountain the remains of Haydn are buried.

EISELEBEN, a town of Prussia, in the province of Saxony, 18 m. W. by N. of Halle, on the railway from Halle to Nordhausen and Cassel; pop. in 1871, 13,434. It contains a castle, and has manufactories of linen, tobacco, saltpetre, potash, and copper, the metal being largely mined in the vicinity. The portion called the old town is surrounded by walls. It is noted as the place where Martin Luther was born and died. The house in which he was born was burned in 1689, but that in which he died is still preserved, and has been converted into a school for poor children. In an upper story of the house several relics of Luther are kept, among which is the album of his friend the painter Cranach, who made the designs for his works. In the church of St. Andrew, the pulpit from which Luther preached but a few days before his death is still preserved.

EISTEDDFODS (from *eistedd*, to sit), meetings of bards held in Wales down to the time of Queen Elizabeth. Several associations have been formed in modern times in Wales which hold periodical meetings called Eisteddfods, as for example the Gwyneddigion, founded in 1770, the Cambrian, founded in 1818, and the Metropolitan Cambrian institution. They seek to preserve the poems of the ancient bards, and to promote national feelings by awarding prizes for Welsh poems, singing, &c. (See BARDS.)

EJECTMENT (Lat. *ejectio firmæ*; Fr. *éjection de firme*), an action for the recovery of

the possession of lands. It was originally applicable to the case of a lessee for years who had been dispossessed; but by the legal fiction of supposing a lease to the imaginary person John Doe, and that he had been ousted by the other imaginary person Richard Roe, it was gradually made the substitute for the cumbrous real actions of the common law, and has come to be the common action, wherever the common law prevails, for the trial not merely of the right to possession, but to the title. To maintain the action it is sufficient that the plaintiff has a present legal right to possession, whether as tenant to another or as owner of the freehold; and a previous peaceful possession is sufficient evidence of such right as against a mere intruder who shows no right in himself. The legal fictions formerly belonging to this action are now generally dispensed with, and it has become one of the most simple and direct of all legal proceedings.

EKHMIN, or *Akhmin* (anc. Eg. *Khemmin*; Gr. *Chemmis* and *Panopolis*), a town of Upper Egypt, on the right bank of the Nile, 60 m. above Siout and 75 m. below Kenneh; pop. about 10,000. It stands on the ruins of one of the most ancient cities in Egypt, the capital of the Chemmim nome in the Thebaid, which was dedicated to Khem or Min, whom the Greeks identified as Pan. In the vicinity of the modern town are the remains of several temples and tombs, and large excavations have recently been made which are expected to throw new light on the condition of the ancient empire, and especially on the nature of the worship of Khem, who is believed to have been a phallic deity. The place contains at present the finest Coptic church in Egypt, and a Coptic and a Franciscan convent. The inhabitants carry on a lively trade in cotton goods and agricultural produce. The name of the town is sometimes given as El-Akhmin, and by the Copts as Khmin.

EKRON, the most northern of the five Philistine cities, assigned in Joshua's distribution of territory to Judah. The ark was taken to Ekron after its capture by the Philistines. Beelzebub was called the god of Ekron, and was here worshipped, and the prophets made this city the burden of some of their most violent denunciations. Its site is occupied by the town of Akir, 10 m. from the Mediterranean, 15 m. S. E. of Jaffa, and 25 m. N. W. of Jerusalem. The present town is built of unburnt bricks; and as there are no ruins, the ancient city was probably constructed of the same materials.

ELAGABALUS, or *Heliogabalus*, *Varius Avitus Bassianus*, a Roman emperor, son of the senator Varius Marcellus and cousin of Caracalla, born in Emesa, Syria, about A. D. 205, killed in Rome in 222. He has been called the Sardanapalus of Rome. While yet a child he

was made priest of Elagabalus, the Syro-Phœnician sun god, in his native city; and the Roman soldiers, beholding the elegant figure of the young pontiff, thought they recognized in him the features of Caracalla. His grandmother, Julia Mæsa, willing to advance his fortune at the expense of her daughter's reputation, spread a report that he was the offspring of an intrigue between her and the murdered emperor. The army, disgusted with the parsimony and rigid discipline of Macrinus, was disposed to admit his pretensions. Elagabalus, as he was called from his sacred profession, took the name of Antoninus, was received with enthusiasm by the troops of Emesa, and declared emperor under the name of Marcus Aurelius Antoninus (218). Macrinus sent detachments of his army from Antioch to crush the rebellion, but the legions murdered their commanders and joined the enemy. At length Macrinus himself marched to meet the pretender, but was signally defeated. He was soon after captured and put to death, and the Roman senate recognized Elagabalus as emperor. His elevation he thought to be due to the power of the sun, which he worshipped in the form of a black conical stone, and Rome saw her hills covered with altars and her streets filled with processions in honor of the god of Emesa. The Palatine hill became the seat of a magnificent temple, where lascivious dances were performed by Syrian damsels. The Quirinal was occupied by a senate of women, who gravely discussed matters of toilet and ceremonial. In a mystical fancy about the sun and moon, he married the Carthaginian priestess of the moon, which was adored in Africa under the name of Astarte. He abandoned himself to the wildest pleasures, but neither a rapid succession of wives, nor a long train of concubines, nor the art of his cooks, could satisfy his passions or save him from satiety. Wearied at length with playing the part of a man, he declared publicly that he was a woman, wished to be dressed like the empress, chose a husband, and worked upon lace. His cruelties were as fantastic as his follies. Having at one time invited the patricians of Rome to a dinner, in the midst of the repast he opened the doors and let in upon them several furious tigers and bears. The patience of the populace and soldiers being exhausted by his vices and tyranny, a sedition was about to break out, when Elagabalus was induced to adopt as his colleague his cousin Alexander Severus. Alexander cherished the rigid manners and primitive usages of Rome, and quickly became the favorite of the army. When Elagabalus sought to withdraw from him the power which he had granted, or to compass his death, the prætorians mutinied, killed the emperor and his mother, and threw their bodies into the Tiber.

ELAM, afterward *Susiana* (called by the Greeks *Cissia* and *Susis*), an ancient country of S. W. Asia, bounded N. by the river Diyaleh, E. by the Kebir Kuh range, W. by the Tigris, and S. by

the Persian gulf. It comprised a low and fertile tract, originally peopled by Turanians and descendants of Shem, who were conquered at a very early time by a Hamitic or Cushite race from Babylon. According to the Biblical account, a very important power had been built up in this region by the time of Abraham. The dynasty of the Chaldean empire mentioned by Berossus after the Median or Aryan, occupying the throne from about 2300 to 2100 B. C., was probably of Elamite origin. It is certain that Chedorlaomer, who belongs to this period, was master of the whole Tigro-Euphrates basin, having as vassals Amraphel, king of Shinar, Arioch, king of Ellasar, and Thargal, the Tidal of the Bible, "king of nations," probably nomadic tribes. He made with them an expedition toward the west, temporarily subjugated parts of Syria, plundered the cities of Sodom and Gomorrah, led Lot away captive, and was at last defeated by Abraham. Ashur-bani-pal mentions in two inscriptions that he took Susa 1,635 years after Kedor-nakhunta or Kudur-nanbundi, king of Elam, had conquered Babylonia, which would give the year 2295 B. C. as the date of the establishment of the Elamite dynasty in Chaldea. Other names of Elamite kings of this dynasty, obtained from inscriptions recently discovered, are: Kedor-mabug and his son Zikar-Sin, Burnaburyash I. and his son Kurigalzu I., Ishmi-Dagan and his sons Gungun and Shamshi-Bin. It is certain that Elam was afterward a formidable feudatory of Babylonia and Assyria, and had its own monarchs and an independent government. An inscription of the 9th century includes Elam in the Assyrian empire; and others show that the Assyrian kings were continually engaged in war with Elamites, who in conjunction with Babylon attempted to assert their independence. About 790 the Elamites became again an independent state under Shutruk-Nakhunta. About 60 years after, Sargon or Saryukin defeated, as he relates in his annals, Humbanigash I., king of Elam, in the plains of Kalu. During the time of Sennacherib, 704-680, Elam revolted again under Kedor-nakhunta II. in concert with Babylon. Sennacherib devastated the whole southern part of the country, and captured Suzub, the Babylonian king, who contrived to escape, and "opened the treasure of the pyramid, the gold and silver of the temples of Bel and Zapanit; he plundered them to give to Uman-Minan, king of Elam," brother and successor of Kedor-nakhunta. Uman-Minan accepted the bribe and joined the invasion of Assyria. Sennacherib bribed in turn Humbarandasha, the Elamite general-in-chief, and gained an easy victory over the combined army of 150,000 men. Babylon and Elam made renewed efforts, and Sennacherib, exasperated by these continued revolts, chastised them with the utmost severity, and the sacred city of Babylon, revered by the Assyrians as much as by the Chaldeans, was given

up to be plundered. Esarhaddon or Asshurakhiddin (680-667) established in the Israelitish territory large numbers of captives from the land of Elam. Esarhaddon and his son Asshur-bani-pal were constantly kept busy by the troublesome and rebellious inhabitants of Elam. Nine kings of Elam are mentioned in the inscriptions of these two monarchs. They maintained the struggle against Assyria without abatement, and often came near overwhelming it, but Asshur-bani-pal put an end to it by devastating the whole country, and reducing the populace to slavery. At the subsequent conquest of the Assyrian empire and its division between Cyaxares and Nabopolassar, the Elamite country was assigned to the Medes. It became afterward part of the Persian empire, forming a distinct satrapy and paying an annual tribute of 300 talents. At the time of Darius the Elamites had regained sufficient strength to venture on an insurrection under Martius, the son of Sisicres, who made himself king, representing himself as Omanes, a descendant of the old native dynasty. Darius relates in the Behistun inscription: "Upon this I was moving a little way in the direction of Elam; then the Elamites, fearing me, seized that Martius who was their chief, and slew him." Shortly after the Elamites joined their old friends the Babylonians in another revolt, which was suppressed in the following year by Gobryas, Darius's general. This was the last effort of the Elamites to regain their independence; their country remained a Persian province, sharing the fortunes of the empire.—In regard to the various names assigned by Greek and Roman writers to the country, Elymais seems to be less comprehensive than Elam, and Susiana and Susis are terms formed artificially from the capital city Susa; Cissia is used by Herodotus as the name of the territory of the Cushites. The modern Khuzistan nearly corresponds to it.

ELAND, a name applied by the colonists of the Cape of Good Hope to the impoofoo (*boscaphus oreas*, H. Smith; *oreas canna* of some authors), an antelopean ruminant, resembling the bovine group in stature, shape, dewlap, and high shoulders. The general color above is a grayish yellow, with rusty and purplish shades shining through it; the lower parts cream yellow; the forehead with long, stiff, yellowish brown hairs; face brownish red, chin white, eyes chestnut; a slight brownish yellow mane, along the back becoming reddish brown; muzzle black; hoofs brownish black, edged above with brownish red hair; the tail is brownish red, with a tuft of yellowish brown; the mane of the dewlap is yellowish brown, pencilled with brownish red. This is the color of the male, which has a small head, a neck tapering above, but bulky toward the chest; the body is thick and heavy; the limbs are elegant and slender; the eyes full and soft, and the expression of the face is gentle and ovine; the horns slope slightly back from the crown, being

very thick at the base, with two spiral turns having an obtuse ridge, and the upper two thirds straight, tapering to a point; the ears are long, narrow, and pointed, hairy on both sides; the hair is rather thin, except on the neck, mane, dewlap, and tuft of tail. The length from nose to base of tail is about $10\frac{1}{2}$ ft., the head being 17 in.; the horns are nearly 3 ft. long; the height at the shoulder is $5\frac{3}{4}$ ft., and at the crupper 2 in. less; the length of the tail $2\frac{1}{2}$ ft., and of the dewlap at its base 20 in. The female is of a pale sienna yellow, deadened with pale brown above; below dirty white, with a cream-yellow tinge; the figure is more delicate and elegant than that of the male, the limbs are more slender, the mane is shorter, the dewlap narrower, the tail less tufted; and the horns are straight, slender, somewhat spiral at the base, with a rudimentary ridge on the spire. The young are of a tint between reddish orange and yellowish brown. This is probably the largest of the antelopes, equalling the horse in

Eland (*Oreas canna*).

height, and weighing from 7 to 10 cwt. It ranges the borders of the great Kalahari desert in herds varying from 10 to 100; rare at present within the limits of Cape Colony, it was found in abundance in the wooded districts of the interior by R. Gordon Cumming. The flesh is most excellent, and is greatly esteemed. When young and not over-fed the eland is not easily overtaken by the Cape horses; but in good pastures it grows so fat that it is easily run down; it is said that when pursued it invariably, if it can do so, runs against the wind, which gives it an advantage in outrunning a horse. The hide is very tough, and much prized for shoes and traces. Like other antelopes, it seems to be independent of water, frequenting the most desert localities far from streams and rivers; except in the breeding season and when pursued, the males generally keep in groups apart from the females. A variety of this species is called bastard eland by the colonists; it is smaller than the other, dark

brownish gray, with a white space between the fore legs. The name of eland, or elk, is applied to this as well as to several other species of deer and antelope by the Dutch colonists of Africa and the Indian archipelago, and is apparently indiscriminately given to any large hollow-horned ruminant; the animal called eland by recent travellers and hunters in south Africa is in most cases the first described species, and probably sometimes the second, as both are found in the same districts, though the herds do not intermingle; they may be the same animal at different ages. These animals are gentle and readily domesticated; but though strong, the shoulders do not possess that solidity which renders common domesticated cattle so valuable. The first specimens brought alive to Europe were received in England in 1842; they all died except one, but others have been imported and the herd has increased rapidly. The first one was killed for the table in 1859; it was five years old, and weighed 1,176 lbs., "huge as a short-horn, but with bone not half the size." The meat resembles beef, with a venison flavor, and has a fineness of fibre and a delicacy of fat which place it high on the list of choice and nutritious articles of food. They are to be seen now in many of the zoölogical gardens of Europe.

EL-ARASH, or **Al-Arish**, also called **LARACHE**, a fortified town of Morocco, capital of the province of Azgar, on the Atlantic coast, 45 m. S. S. W. of Tangier; pop. about 5,000. It is built on two hills on the southern bank of the wady El-Khos or Luccos, is surrounded by walls, and contains an exchange, a bazaar, a fine mosque, and a dilapidated castle occupied by the governor of the province. The fortified harbor is about $\frac{1}{4}$ m. wide and 1 m. long, with an average depth of 24 ft. The exports consist mainly of grain, wool, hides, beans, and cork. The beautiful orchards and pleasure gardens from which it derives its name are suffering from neglect, though some olives and oranges are cultivated. —The town stands probably on the site of the ancient Lixus, on the river of the same name, but only a few Roman ruins have been discovered here. Opposite, on the right bank of the wady El-Khos, are the ruins of the Phœnician colony Lex or Lix (Arabic, *Teshemis*), and several tombstones with Phœnician inscriptions have recently been found. The wonderful island and gardens of the Hesperides were located by the ancients at the mouth of this river, which accordingly sometimes received the name of Hesperides. The island now found here is about 600 ft. long and 120 ft. wide. The town was occupied by the Portuguese during the 17th century, and became the centre of a large export trade in African produce. In 1829 the Austrian fleet destroyed here the pirate fleet of Morocco.

EL-ARISH, or **Kalat el-Arish**, a fortified town in Lower Egypt, on the Mediterranean near the mouth of the wady El-Arish; pop. about 2,000. It is the frontier town between Egypt and

Syria, and as such a great centre of inland traffic between the two countries. Since the construction of railways through the Delta it has lost much of its maritime importance. The fortifications are insignificant.—At this place stood the ancient Rhinocorura or Rhinocolura, an Egyptian penal colony, which is said to have derived its name from the convicts having their noses cut off. Baldwin I., king of Jerusalem, returning from his Egyptian expedition, fell sick and died here in 1118. The French defeated here the Turks, captured the town, and reduced the fort in February, 1799. The place was retaken by the grand vizier in December. The convention for the evacuation of Egypt by the French was concluded here, Jan. 24, 1800, between Gen. Kléber, Sir Sidney Smith, and the grand vizier.

ELASMOSAURIANS, a genus of gigantic marine saurians, of the cretaceous epoch, whose remains have been found especially in New Jersey. These, with the huge mosasaurus, the

Restoration of an Elasmosaurus.

pythonomorphs of Prof. Cope, were the sea-serpents of the close of the mesozoic age. They seem to have combined the features of serpents, lizards, and plesiosaurs, and to have resembled the *varanidae* of the tropics of the old world more than any other living type. The *elasmosaurus*, with the allied *cimoliasaurus*, both found in New Jersey but not elsewhere in America, and in England, were reptilian whales; the latter genus resembled the plesiosaurus, while the former had an enormously long and flattened tail; in both, the zygapophyses or processes connecting the vertebral arches are very oblique, with their articular faces turned opposite to that which prevails among vertebrates generally. The *E. platyrus* had vertebrae nearly as large as those of an elephant; the bulk was whale-like, the neck long and flexible, the paddles short, and the tail serpent-like; skull light, with long, narrow, and flat muzzle; nostrils or spout holes near

the orbits; teeth long, cylindrical, very sharp, and fitted for seizing the fish upon which it fed. It attained a length of 45 feet, and might well furnish a model for the modern sea serpent, which in the light of geology is not a zoölogical impossibility.

ELASTIC CURVE, the curve assumed by a straight spring of uniform thickness when the ends are brought forcibly together. It embraces a variety of appearances, simple waves, overlapping waves, a figure of eight, retrograde loops or kinks, ordinary loops, and the circle. The fundamental law or equation of the curve is that the curvature of each point is directly proportional to its distance from a certain straight line on which the curvature is zero; so that when the curve crosses this line it reverses the direction of its curvature.

ELASTICITY, the property in virtue of which a body tends to recover its form and dimensions on the removal of the forces by which these have been changed. A perfectly elastic body is defined by Thomson and Tait (1872) as one which "when brought to any one state of strain requires at all times the same stress to hold it in this state, however long it may be kept strained, or however rapidly its state may be altered from any other strain or from no strain to the strain in question." According to Maxwell (1872), a perfectly elastic body is one "which, subjected to a given stress at a given temperature, experiences a strain of definite amount, which does not increase when the stress is prolonged, and which disappears completely when the stress is removed." If the form of the body is found to be permanently altered, its state of stress just previous to the change is called the limit of perfect elasticity. If the stress increases until the body breaks, the value of the stress is called the strength of the material. If breaking takes place before there is any permanent alteration of form, the body is said to be brittle. If the stress, when it is maintained constant, causes a displacement within the body which increases continually with the time, the substance is said to be viscons. Viscosity, whether in solids or fluids, is then intimately connected with their elasticity, and the preceding definitions of elasticity, although popularly associated with the behavior of solid bodies, are equally applicable to liquids and gases; indeed, strictly interpreted, they have reference to the behavior of the molecules and ultimate atoms of which bodies are supposed to be composed. A perfect knowledge of the laws of elasticity is nothing less than a knowledge of the exact laws according to which atoms attract and repel each other, or, more generally, of the ultimate constitution of matter. In this broad sense this subject offers the most important and at the same time the most difficult field of study that can be cultivated by the physicist. The ultimate constitution of matter is in fact as truly the goal of the modern physical and chemical sciences, as the constitution of the universe is the final problem of astrono-

my. The tendency of modern physics is to look with distrust upon all theories of molecular action that assume the principle of action at a distance. When, however, we have attained to a correct knowledge of the internal constitution of bodies, it may be expected that the laws of elasticity will be deduced therefrom by mathematical processes. Until then the subject of our article must be treated inductively, except in so far as we assume the relative position of the particles of bodies to be disturbed only to an indefinitely small degree by the exterior forces; in these cases the molecular motions may be deduced from the established general laws of mechanics, and have indeed been so investigated with great success by a host of scientists, beginning with Bernoulli, Young, Fresnel, and Green. The general investigation of the relation between the strains and deformations of a solid has been shown by Green (1830) to depend upon the solution of a quadratic equation having 6 unknown quantities and 21 terms whose coefficients are essential for a complete theory of the dynamics of an elastic solid subjected to infinitely small strains. I. **ELASTICITY OF MASSES.** The elastic properties of homogeneous bodies relate to the behavior either of the constituent molecules and sensible masses of the bodies or of their ultimate atoms to each other. In considering the latter class of relations we have to do with chemical changes and the properties of heat, light, electricity, and magnetism. Considering the behavior of molecules, we have to do with the laws of strength of materials, elasticity of springs, propagation of sound, &c. The latter class of phenomena will here first attract our attention, and we shall treat in succession of solids, jellies, fluids, vapors, and gases, concluding with some of the relations between the molecular elasticities of these bodies and the agencies of heat, light, and electricity.—Our first ideas as to the elasticity of solids are derived from the properties of extension and compression under forces respectively of tension and pressure. In the second column of the following table is given for each substance the weight necessary to extend by $\frac{1}{100}$ part of its length (or one centimetre) a bar whose section is one square millimetre, and whose length is one metre:

SUBSTANCE.	Weight in Milligrammes.	Modulus in Kilogrammes per sq. mm.	Modulus in pounds per sq. inch.	Specific gravity.	Modulus of length in metres.
Flint glass.....	555.1	5.551	8,800,000	8.3	19,000
Brass.....	1,094.8	10,948	15,400,000	8.3	91,000
Copper.....	1,255.8	12,558	17,500,000	8.9	111,000
Cast iron.....	1,374.1	13,741	19,500,000	7.25	99,000
Wrought iron.....	1,399.4	13,994	20,400,000	7.5	150,000
Steel.....	2,173.3	21,733	30,900,000	7.85	170,000

When the elongations are small they are, according to the law of Hooke, directly proportioned to the tension or the applied weight; therefore in the preceding cases weights ten times as great as those in the second column

will extend the bars to double their original length, if we suppose the material to withstand such a force without breaking; the corresponding numbers are found in the third column of the preceding table, and constitute for each substance the so-called "Young's modulus of elasticity," which may be defined as the weight that will so elongate a bar of unit square section as to double its original length. The moduli given in the third column in kilogrammes per square millimetre may be converted into the British system of pounds per square inch by multiplying by 1,422·3, as given in the fourth column. It is frequently convenient to express the above given weight modulus by an equivalent length of a bar of the same material; this number, which may be called the length modulus, is found by dividing the weight modulus by the weight of the unit of length, or in the French system, by the specific gravity of the substance and multiplying the quotient by 100,000. Thus a bar of glass will be stretched to double its length by the weight of a similar bar of glass whose length is 19,000 metres. In general, for large forces and changes of form that leave a permanent deformation of the solid, the resistance to crushing differs from the resistance to stretching; this is shown by the coefficients of strength for these two kinds of forces; and the difference of bodies in this respect is a highly important element in calculating their fitness for building or mechanical purposes. On the other hand, the effect of an exceedingly small force in producing a slight compression is sensibly equal to the effect of the same force in producing a slight extension; therefore the above given moduli of elasticity hold good for such values of both pressure and tension as do not approach the limit of perfect elasticity. If now a bar of any substance be slightly bent, its convex side is extended, but its concave side compressed; there must therefore be within its substance some neutral line, or axis of no change whatever; this line constitutes the elastic curve of Bernoulli, and has been the subject of many investigations. The exact curvature of this line, or of the bar, is known when the applied forces are given. The formulas relating to the various cases that occur in engineering are given in works on applied mechanics, such as those of Weisbach and Rankine. One of the most interesting and important applications of the elasticity of a plane curved spring is found in the case of the mainspring and especially of the hair spring of a chronometer; the theory of their action has been studied, among others, by Yvon Villarceau (1863). Other applications are found in the dynamometer for measuring great tensions, the horizontal fixed glass thread for weighing minute quantities, the tuning fork and the stretched strings of musical instruments, &c. —The near approach to perfect elasticity that is the property of some bodies, as steel and glass, is evinced by the perfect uniformity of

the times of vibration of the strings, bells, bars, &c., that give out pure musical notes on being struck, and that no matter how extensive their arcs of vibration or how loud their corresponding notes; if the elastic force did not increase precisely in proportion to the amount of the molecular displacement, we should notice discords instead of the single pitch that emanates from the sounding body. The perfect uniformity of these minute vibrations has suggested their application in the sphygmograph and other chronographs, where they replace the pendulum for the measurement of minute intervals of time; indeed, in the chronograph of M. Hipp, a vibrating spring serves also as the regulator of the revolving cylinder. The vibrations of a carefully arranged metallic spring, hermetically sealed in an exhausted glass vessel, and at a standard temperature, depending as they do solely on the elasticity of the body, offer a means of measuring small intervals of time with almost absolute perfection; and Sir William Thomson has suggested that for scientific purposes such an arrangement must be adopted as a standard far more constant than the rotation of the earth or the vibration of a pendulum.—If a straight bar be twisted about its longitudinal axis, an elastic force is brought into play to resist the mechanical couple by which the twisting is effected. This, the elasticity of torsion, does not depend upon that of compression or extension; its modulus must therefore be determined by direct experiment. The laws of the elasticity of torsion have been studied originally by Coulomb, and subsequently by Binet, J. Thomson, and especially by St. Venant (1855) and Thomson and Tait. The principal applications of torsional elasticity are found in the spring balance in ordinary commercial use, and in the torsion balance used in electrical measurements, in the Cavendish experiment, and other delicate researches. In the latter instrument the amount of torsion is evidently a direct measure of the external force applied and to be measured. In the former instrument (the spring balance) the elastic wire is coiled around a cylinder like the threads of a screw, and an external force is applied parallel to the axis of the cylinder to increase or diminish the distance between the coils. The theory of the action of such spiral or helicoidal springs has been developed by Binet (1814), and by Prof. J. Thomson (1848), by whom it has been shown that the force that opposes the elongation or contraction of a helicoidal spring is the elasticity of torsion. Besides the applications above mentioned of the spring balance to commercial uses, it has been proposed to use a very delicate instrument of this construction as a means of investigating the local and general variations of gravity on the earth's surface, for which purpose it possesses some advantages over the pendulum.—The grandest application of the laws of the elasticity of solids that has yet been made consists in the investigation into

the elasticity of the earth, considered as a whole, which is an important element in the theory of oceanic tides. Sir William Thomson, who has given much attention to this problem, concludes (1871) that the earth has considerably more average rigidity than a globe of glass of the same size; were it not so, the yielding of the solid earth to the tidal influence of the sun and moon would to a great degree annul the observed ocean tides.—The elasticity of a body subjected to a severe strain is in general permanently injured; and Messrs. Hodgkinson and Fairbairn (1837) concluded from their experiments on iron, &c., that the limit of perfect elasticity is much lower than was formerly conceived; that, indeed, a permanent set takes place in ordinary cast iron on the application of even a very slight force; and that there is in general no clearly defined limit of perfect elasticity. This conclusion is probably applicable only to the metals as found in commerce, and not to chemically pure homogeneous or crystalline masses. The ease with which a solid body receives a slight permanent set or deformation is expressed by the words soft and plastic, and the stress on a unit section exerted at the time the body breaks or crushes is the coefficient of rupture; at the limit of perfect elasticity the investigation of elasticity proper ceases, and the phenomena become those of viscosity, as previously defined, until the force applied causes a rupture of the body.—In connection with the elastic properties of solids there remain to be noticed the phenomena of impact. When two bodies strike each other, the portions in contact are forcibly compressed; and as no body is perfectly inelastic, they begin to separate as soon as the compression reaches its maximum value. Newton found that the relative velocity of separation after impact bears a proportion to the previous relative velocity of approach, which is constant for the same two bodies; this proportion is always less than unity, but approaches that limit the harder the bodies are. To this proportion the name coefficient of elasticity is frequently given; this, however, is a misnomer, and Thomson and Tait suggest the more appropriate term coefficient of restitution, while others call it the coefficient of impact. The quantity of force, if any, that is apparently annulled on the collision of two bodies, is not destroyed, but is converted into the other forms of molecular elasticity, *i. e.*, the vibrations of sound, heat, light, and actinism, which spread in all directions to indefinite distances from the place of their origin.—Crystalline bodies differ from homogeneous ones, so far as concerns their elastic properties, only in that the coefficient of elasticity varies with the direction of the external forces that produce the strain.—Jellies form a class of solids distinguished by a wide range of distortion possible within the limits of perfect elasticity, or without producing permanent deformation. In solid bodies the limit of perfect elasticity varies

from something indefinitely small, as in most hard bodies, to a number as large as 1·1 or 1·2, as in the case of cork, and to 2 or 3 in the case of India rubber; the latter is, in its purest state, more properly allied to the class of jellies. In the vibration of solids it has been observed that a force generally called internal or molecular friction resists the vibrations and diminishes their amplitude; this resisting force is probably nothing but the transformation of a portion of the vibratory movement of the mass into heat vibrations. The development of internal friction is specially notable in the vibrations of jellies; it is allied to, if not the same as, the property of viscosity in fluids.—The distinctive property of a fluid is that its molecules can quickly, easily, and permanently change their relative positions; a perfect fluid is a body incapable of resisting a change of shape, provided only that its volume be not altered. Fluids are divided into the two classes of liquids and gases, according to the relative values of their coefficients of elasticity and viscosity.—The elasticity of liquids is generally known as their compressibility, which property has reference to the behavior of the interior of a mass of liquid; the phenomena of capillarity, on the other hand, depend on the peculiar elastic condition of the superficial film of a mass of liquid. "The coefficient of elasticity of a fluid is the ratio of any small increase of pressure to the cubical compression thereby produced. The elasticity however varies with certain conditions that may be imposed, such as that the fluid be under a given pressure or exposed to a given temperature. Every substance has two elasticities, one corresponding to a constant temperature, the other corresponding to the case where no heat is allowed to escape from the body during the process of compression. In the latter case the elasticity is always greater than in the case of uniform temperature." The following are the coefficients of compressibility of several liquids, or the fractions by which the original volume is diminished for an increase of pressure of one atmosphere or about 15 lbs. to the square inch:

Substance.		Coefficient of elasticity.
Mercury at a temperature of 32° Fahr.	82	0·000003
Water " " "	107	0·000050
Alcohol " " "	45	0·000044
Ether " " "	32	0·000111
" " "	57	0·000140

The other and highly important property, the superficial elasticity of liquids, is commonly known as the phenomena of thin films, of capillarity, &c, and is well illustrated by the blowing of a soap bubble, which operation is but the forcible stretching of a superficial sheet of a highly elastic liquid membrane. The superficial tension of the latter may be measured in grammes weight per linear metre or other unit; it is the same whether the globe be hollow or full; it varies with different liquids and with the nature of the gas or other fluid

contiguous to the thin film. The following table contains some results obtained by Quincke; the figures hold good for the temperature of 20° centigrade and the above units of weight and length :

LIQUID.	Tension of surface separating the liquid from	
	Air.	Water.
	Grammes.	Grammes.
Water.....	8.253	0.000
Mercury.....	55.03	42.53
Olive oil.....	3.760	2.10
Turpentine.....	3.030	1.18

The investigation of the superficial tension of liquids leads to the explanation of the phenomena of capillarity, evaporation, the wetting of surfaces, the condition of vapor in clouds, or of vapor vesicles if such there be, &c.; and thus brings these diverse subjects within the range of the laws of elasticity.—The elasticity of vapors, or more strictly their expansibility, is a matter of such importance in connection with the steam engine, &c., and in meteorology, that it will be specially treated of under those heads. By the removal of pressure or the communication of heat, or both, a solid or liquid may be converted into a more or less perfect gas, usually called a vapor. The vapors generally have coefficients of elasticity that depend almost wholly upon the temperature; a few such are given in the following table, from Regnault :

Temperature, centigrade.	Alcohol, millimetres.	Ether, millimetres.	Water, millimetres.
-20°	3.3	63.9	0.9
0	12.7	154.4	4.6
+20	44.5	432.8	17.4
40	133.7	907.0	54.9
60	350.2	1725.0	148.3
80	512.9	3022.8	354.6
100	1697.6	4953.3	760.0
120	3231.7	7719.2	1491.3
140	2717.6

—The elasticity of a gas is its power to resist compression, and to restore either its original volume or its original tension. At ordinary temperatures all gases are perfectly elastic, so far as the most delicate measures have as yet been able to determine, for the most extreme changes of pressure. The limits of perfect elasticity are therefore practically infinite; thus justifying the law first announced by Boyle, though frequently spoken of as the law of Mariotte, because firmly established by him, that the density of a gas is directly, or its volume inversely, proportional to the pressure. The elasticity of gases, being to a high degree independent of temperature, finds an important application in mechanical engineering, in the transmission of power to great distances by means of compressed air. It is through this elastic property of the air that sounds are conveyed by it at the rate of about 1,100 feet

per second in all directions. II. ELASTICITY OF MOLECULES AND ATOMS. The explanation of the phenomena of heat and light has led to the assumption of the existence throughout all space of a highly elastic gas, the ether of physical science; the vibrations of the molecules of this ether, being communicated to the nerves of the body, produce the sensations of heat and light. This gas is supposed to exist, though in a state of constraint, among the atoms of transparent bodies, and the mathematical development of the nature of its molecular vibrations offers a complete explanation of all the phenomena of optic and thermic science; and indeed, according to Maxwell and Edlund, we can use this same ether for the explanation of the phenomena of electricity and magnetism. Its elasticity is such that heat, light, and electricity are transmitted by it at the rate of about 200,000 miles per second through the interplanetary spaces. It is in general homogeneous, but in the interior of many crystalline bodies its elasticity varies as does that of the material of the crystal, thus producing the phenomena of polarization, double refraction, &c. While heat itself apparently consists of molecular vibrations depending on the elasticity of the ether, it on the other hand exerts a marked and highly important influence over the elasticity of bodies. So intimate is this connection that it may indeed be doubted whether the elasticity of the ether can be properly spoken of as distinct from the elasticity of the more material bodies that are recognized by the methods of chemical science. In general an excess of heat induces such molecular vibrations that the constituent atoms become separated from each other, producing in the chemical nature of the body the changes known as dissociation, changes that may be compared with the rupture or crushing of a solid mass when subjected to too great a stress. When, on the other hand, a more moderate degree of heat is applied, most interesting changes occur, which will be briefly indicated in so far as they affect the elasticity of the substances. The elasticity of solid bodies is in general diminished by heat, thus tending to lengthen the time of vibration of chronometer springs, tuning forks, &c., retarding the velocity of sound waves, contracting the limits of perfect elasticity, diminishing the force of cohesion or the strength of the material, increasing its plasticity, diminishing its viscosity, &c. Iron and steel are among the few known instances of departure from this general rule. The elasticity of liquids is so affected by heat that, according to Gladstone and Dale, the index of refraction and the coefficient of dispersion diminish as the temperature increases. An increase of temperature diminishes the compressibility of water, but increases that of ether, alcohol, and chloroform. With regard to vapors and gases there seems to be one uniform rule, *i. e.*, that an increase of heat increases the elasticity of these forms of matter. The pre-

ceding table from Regnault has shown the connection between temperature and elastic pressure for some of the more interesting vapors. For short distances on either side of the boiling point of a liquid the elasticity of its vapor approximately varies directly as the temperature, as was first propounded by Dalton. In considering the effects of heat on the elasticity of a vapor or a gas, it is necessary to distinguish between (1) the elastic pressure exerted by a gas that is confined within a constant volume and has its temperature altered by external heat, and (2) the pressure exerted by a gas that is compressed by external force to a smaller volume, but whose temperature is not altered. The former is the elasticity under constant volume or the expansion under constant pressure; the latter is the elasticity under constant temperature, and is for perfect gases expressed by Boyle's law, which however holds good only approximately for vapors. Gay-Lussac has shown that the expansion under constant pressure is sensibly the same for all perfect gases, and is such that the volume increases by 0.002036 of its original value for an increase of 1° F., or by 0.00367 for an increase of 1° C. This law was fully confirmed by Regnault, who showed that it is only approximately true when gases or vapors approach the point of liquefaction. The effect of heat on the elasticity of a gas is so combined with its effect on the density as in general to increase the velocity of the transmission of sound. Thus in air at a pressure of 30 inches the velocity in feet per second is 1,089 at a temperature of 32° F., but is 1,131 at a temperature of 70° F.

ELATERIUM (Gr. *ēlabveiv*, to drive out), a substance deposited by the juice of the fruit of *momordica elaterium*, or squirting cucumber, a plant of the order *cucurbitaceæ*, growing in the south of Europe. (See CUCUMBER.) It is found in thin flat cakes of a gray or greenish color, which have a feeble odor and a slightly bitter taste. Its medicinal activity depends upon a crystalline, neutral, active principle, called elaterine. This is insoluble in water and alkaline solutions, sparingly soluble in dilute acids, and freely soluble in alcohol. The proportion of elaterine in different specimens of elaterium varies exceedingly, and the medicinal activity of the latter article varies proportionally. Elaterium and its active principle elaterine are violent cathartics, and also increase somewhat the secretion of urine. In small doses, that is, from $\frac{1}{16}$ to $\frac{1}{32}$ of a grain of elaterine and from $\frac{1}{8}$ of a grain to 2 grains of elaterium, these articles produce copious watery discharges, which are frequently attended with nausea, vomiting, and depression. In larger doses they act with great violence upon the stomach and bowels, and in still larger doses excite an inflammation of these organs which has sometimes proved fatal. Their action is rapid. They generally purge in an hour or less, and a legitimate dose may be repeated in an hour if it has not acted by

that time. On account of the energy of their operation, they are not much used medicinally except when, in the treatment of dropsy and disease of the kidneys, it is desirable to obtain copious, frequent, and watery evacuation. They should always be administered cautiously, and never given when great constitutional weakness exists.

ELATH (in Josephus *Ælane*, in Roman geography *Elane*, now *Ailah*), a seaport of ancient Idumæa, on the shore of the eastern or Elanitic gulf of the Red sea, now the gulf of Akabah. It was a part of David's conquest from the Edomites; was a place of great importance in Solomon's time, as the port in which he built and fitted out his ships for bringing gold from Ophir; was captured by the revolted Edomites in the reign of Joram, after having been in the possession of the Israelites 150 years; was retaken by Uzziah, who fortified it anew, peopled it with his own subjects, and restored the trade to Ophir; was afterward taken by Resin, king of Damascus, who in turn was deprived of it by Tiglath-pileser, king of Assyria, from whose time it was never recovered by the Jews. Later it fell under the power of the Romans, became the residence of a Christian bishop, and submitted to the Moslems, its governor paying them an annual tribute. In 1116 it was taken by King Baldwin of Jerusalem, and in 1067 was again wrested from the Christians by Saladin. Edrisi describes it as a small town frequented by Arabs, and forming an important point on the route between Cairo and Medina. Elath adjoined Eziongaber; and Akabah now occupies the site of one or both of these ancient towns.

ELBA, an island in the Mediterranean, belonging to the Italian province of Livorno, separated from the mainland by the strait of Piombino; length about 18 m., greatest breadth 12 m.; area, about 90 sq. m.; pop. about 20,000. Its outline is irregular, the mountains which traverse the island rising in some parts more than 3,000 ft., and being indented by deep gulfs and inlets, so that its breadth in some places does not exceed 3 m. The soil is fertile, but only a small portion is under tillage. The valleys abound with fruit trees, but are not well cultivated, and the fruits are of inferior quality, excepting oranges. Among the annual products of the island and its waters are red and white wine, marine salt, tunnies, sardines, anchovies, and other fish, and iron, for which the island has always been celebrated. The iron is found in a mountain near Rio, on the E. coast, about 2 m. in circumference, 500 ft. high, and yielding from 50 to 75 per cent. pure metal. There are quarries of granite in the S. W. part of the island, in which crystals of red and green tourmaline and emeralds are found. The principal towns are Porto Ferrajo, Porto Longone, Rio, and Marciana. The island was called *Æthalia* by the Greeks and *Ilva* by the Romans, and was noted for its minerals. Ancient ruins

are still visible in several places. During the middle ages it was ruled by various Italian princes and chiefs. In 1548 Charles V. ceded the territory of Porto Ferrajo to Tuscany. Afterward the island was successively governed by Spain, Naples, and the lords of Piombino.

Porto Ferrajo, Elba.

From July, 1796, to April, 1797, it was occupied by the British. It was then ceded to France, and in 1801 united with the new kingdom of Etruria. The treaty of Paris in 1814 erected Elba into a sovereignty for Napoleon I., who resided there from May 4, 1814, to Feb. 26, 1815. During his brief sovereignty Napoleon caused a road to be built uniting Porto Ferrajo with Porto Longone. The villa of San Martino near Porto Ferrajo, which was occupied by Napoleon, has been converted into a Napoleonic museum, and contains various objects of interest relating to the first empire. (See *Napoléon à l'île d'Elbe*, by Amédée Pichot, Paris, 1873.) In 1815 Elba reverted to the grand duke of Tuscany, and with the rest of his territory was annexed to the kingdom of Italy in 1860.

ELBE (Bohem. *Labe*; anc. *Albis*), a river of Germany, rising in Bohemia, near the frontier of Prussian Silesia, and flowing into the North sea below Glückstadt in Holstein. It is about 700 m. long. It originates in a number of springs on the western slope of the Schnee-Koppe (snow summit), one of the peaks of the Riesengebirge, at an elevation of about 4,500 ft.; runs mainly in a N. W. course; is navigable from its confluence with the Moldau, and has but a very slight inclination, its bed 40 m. from its sources being but 658 ft. above the sea. Its chief affluents are: on the right, the Iser, Black Elster, and Havel; on the left, the Moldau, Eger, Mulde, Saale, Jetze, Ilmenau, and Oste. The chief places on its banks are Josephstadt, Königgrätz, Theresienstadt, and Leitmeritz, in Bohemia;

Pirna, Dresden, and Meissen, in Saxony; Torgau, Wittenberg, Magdeburg, Lauenburg, Altona, and Glückstadt, in Prussia; and Hamburg. Its channel between Hamburg and the sea admits of the passage of vessels drawing 14 ft. of water at all times, but is much encum-

bered with sand bars and shoals. By means of its own waters and those of the numerous canals branching from it, the Elbe places all N. W. and central Germany in connection with the seaboard. Wood, stones, fruits, and earthenware are exchanged through it for corn, salt, and colonial produce. But until recently its navigation has been much complicated by the regulations of the states through which it runs. These regulations were the subject of much controversy and negotiation. By the *Elbschiffahrtsacte* of June 23, 1821, the entire

navigation of the Elbe was thrown open to the commerce of the world, and the charges to which it was subject were fixed and rendered uniform. The regulations were still further modified by conferences which were held from time to time for their revision, and particularly by the additional act of April 13, 1844. The toll collected at Stade was abolished July 22, 1861, and finally all the remaining tolls were removed by act of the North German confederation, which went into operation July 1, 1870. The numerous river transportation companies are thus enabled to compete at better advantage with the railways, and the amount of business has been much increased.

ELBERFELD, a city of Rhenish Prussia, on the Wupper, a branch of the Rhine, in the district and 16 m. E. N. E. of the city of Düsseldorf, with which it is connected by the Bergisch-Märkische railway; pop. in 1871, 73,394. The town of Barmen adjoins it on the east, and the two towns taken together form one of the most important manufacturing centres of Germany. The number of looms in Elberfeld employed in the cotton manufacture in 1871 was estimated at 6,000, and the value of the products at \$13,000,000. There are besides large manufactories of silks, ribbons, carpets, carriage and furniture stuffs, buttons, machinery, &c. The establishments for dyeing are particularly celebrated. The railway has its principal office here, and every year extends its connections. A large amount of business is transacted at the two fairs which are held here annually. The finest public buildings are the council house, the court house, the new post

office, the railway station, the casino, the hospital, and the orphan asylum. It is the seat of a mercantile and other courts; has a gymnasium, and numerous schools, including one for teaching the management of the Jacquard loom and pattern drawing. Elberfeld is the centre of the Protestant Bible and missionary societies. It was originally settled in 1527 by refugees from the Netherlands, and of late years has increased in importance from the adoption of improvements in spinning. Though the town is mainly of recent origin, it is irregularly built, but the number of handsome private residences is increasing. West of the town is a hill called the Haardt, on which stands a round tower commanding a fine view of the valley of the Wupper; it is surrounded by a handsome park.

ELBERT, a N. E. county of Georgia, separated from South Carolina by the Savannah river, bounded S. and W. by Broad river; area, 514 sq. m.; pop. in 1870, 9,249, of whom 4,863 were colored. The surface is hilly, and the soil, particularly near the rivers, is fertile. Near the Savannah river are several remarkable artificial mounds, one of which is 40 or 50 ft. high and has a large cedar growing on its summit. The chief productions in 1870 were 22,736 bushels of wheat, 140,435 of Indian corn, 13,263 of oats, and 3,035 bales of cotton. There were 1,051 horses, 1,848 milch cows, 2,957 other cattle, and 7,097 swine. Capital, Elberton.

ELBEUF, a town of Normandy, France, in the department of Seine-Inférieure, on the left bank of the Seine, 13 m. S. S. W. of Rouen, and 63 m. N. W. of Paris; pop. in 1866, 21,784, and rapidly increasing. It manufactures double-twilled and water-proof cloth, billiard-table cloth, flannels, zephyrs, and light woollens of high finish. It has also dye houses, foundries, machine shops, and manufactories of soap and chemicals. The total value of goods manufactured annually is estimated at nearly \$18,000,000. Many of the workmen employed reside in neighboring villages; the whole number is estimated at 24,000. The town has eight artesian wells and six public fountains. There is daily communication with Rouen by steamers, and Elbeuf is connected with the village of St. Aubin, on the opposite side of the river, by a suspension bridge. It has a tribunal of commerce, a library, societies for the encouragement of the industrial arts, &c. The finest churches are those of St. Etienne and St. Jean.

ELBING, a town of Prussia, in the province of West Prussia, and in the district and 34 m. E. S. E. of the city of Dantzic, situated upon a river of its own name, 5 m. from the Frische Haff; pop. in 1871, 28,600. The city is composed of the old and new towns, and several suburbs, and is in part enclosed within ancient fortifications. It has one Catholic and nine Protestant churches, a synagogue, a gymnasium in which is the city library of 24,000 volumes, and several hospitals and charitable

institutions, including one founded by an Englishman named Cowle, in which 400 children are educated. The principal manufactures are of sugar, pearlsh, tobacco, soap, chiccorey, vitriol, sail cloth, and leather and woollen fabrics. Ship building, especially of iron, has of late become of great importance. On account of the shallowness of the Frische Haff, foreign commerce is carried on by way of the Kraffohl canal (from Elbing to the Nogat, a branch of the Vistula) and Dantzic; but as Elbing communicates with the lakes of E. Prussia through the Oberländische canal, its inland business is large. The chief exports are grain, timber, staves, hemp, flax, feathers, horse hair, wool, fruit, butter, and manufactured goods.

ELBURZ, *Elbruz*, or *Albarj*, a lofty range of mountains extending over northern Persia, connected on the west with those of Armenia and with the great Caucasus chain, and eastward with the Paropamisian range. It averages from 6,000 to 8,000 ft. in height, the highest peak, Mt. Demavend, being about 18,000 ft. (See *DEMAVEND*.) It enters N. Persia from the Caucasus, and runs for some distance parallel with the S. shore of the Caspian to Astrabad, whence it branches off in an easterly direction toward Afghanistan and Turkistan. By the Sahund mountains it also connects with the Zagros range on the Turkish border. The valleys of the Elburz, especially toward the S. declivities, are exceedingly fertile. In the slope of the mountains opposite Teheran is the tract of Shama-i-Iran or Shamirun (*i. e.*, the light of Persia), extending over 20 m., and containing nearly 40 villages surrounded by gardens and famous as summer resorts. The most celebrated pass is that of Sardari, known to the ancients as the Caspian gates, situated about 55 m. S. by E. of Mt. Demavend, and extending nearly 30 m. in a narrow road between high rocks, forming a barrier against foreign enemies.—One of the principal summits of the Caucasus range is also known as Mt. Elbruz, or Elburz, 18,514 ft. high. (See *CACCASTUS*.)

ELCSAITES, a sect of Asiatic Gnostics, founded in the reign of Trajan, about the beginning of the 2d century, a branch of the Jewish Essenes, kindred to and finally confounded with the Ebionites. A Jew named Elxai or Elkesai is supposed to have been their founder. Their most distinctive tenet was that man is but a mass of matter in which the divine power is concealed. They believed in the repeated and continuous incarnation of Christ, were tenacious of their oaths, practised circumcision, abstained from meat, favored early marriages, and rejected portions of the Old Testament and the epistles of Paul.

ELCHE (anc. *Illici*), a town of Spain, in the province and 16 m. S. W. of the city of Alicante, on the river Tarafa, 10 m. from the Mediterranean; pop. (including the surrounding plantations) about 20,000. It is girdled on every side by forests of palm trees, and has

been named the city of palms. The chief industry is the culture of dates, which is conducted with great skill. The leaves of the male and barren female palms are sent to all parts of Spain for use in the processions and decorations of Palm Sunday.

ELCHINGEN, *Ober* and *Unter*, two villages of Bavaria, situated on the sides of a steep mountain near the Danube, about 3 m. apart and 7 m. N. E. of Ulm. At Ober Elchingen was fought, Oct. 14, 1805, one of the most famous battles of the campaign of Austerlitz. For his conduct in this battle Marshal Ney received the title of duke of Elchingen. In the upper village is a Benedictine abbey founded in 1128, and celebrated in the middle ages.

ELDER, an overseer, ruler, or leader. The reverence paid to the aged in early times was doubtless the origin of this title, it being used as a name of office both among Jews and Christians. Macknight thinks it was applied in the apostolic age to all, whether old or young, who exercised any sacred office in the Christian church. Elders or seniors, in the ancient Jewish polity, were persons noted for their age, experience, and wisdom; of this sort were the 70 whom Moses associated with himself in the government of Israel, and such also were those who afterward held the first rank in the synagogue as presidents. In church history, elders were originally those who held the first place in the assemblies of the primitive Christians. The word *presbyter* is sometimes used in the New Testament in this signification, and as interchangeable with *ἐπίσκοπος*; and hence the first meetings of Christian ministers were called *presbyteria*, or assemblies of elders. Among the Baptists, ministers of the gospel generally are called elders. In the Presbyterian churches they are the officers who, in conjunction with the ministers and deacons, compose the church session, representing the church itself, conducting its discipline, and aiding in the promotion of the interests of religion. They are chosen from among the people, usually for life; are generally set apart to their office with some public ceremony; and their number is different in different churches.—It has long been a matter of dispute whether there are any such officers as lay elders mentioned in Scripture. On the one side, it is said that these officers are mentioned separately from the brethren, and that their office is described as being distinct from that of preaching, he that ruleth being expressly distinguished from him that exhorteth or teacheth. On the other side, it is contended that the distinction alluded to does not refer to different orders of officers, but only to the degree of diligence with which they discharge their duties.

ELDER, the popular name of plants of the genus *sambucus*. The most common American elder, *sambucus Canadensis*, Linn., is a showy shrub, well known from its numerous flat cymes of white flowers appearing in June, to

be succeeded by heavy black-purple, crimson-juiced berries in August, and overtopping the wild reeds and bushes on the borders of fields. On account of its long and spreading roots it is sometimes troublesome to the farmer. A wholesome sudorific decoction is prepared from its flowers, which are carefully gathered and

Sambucus Canadensis.

dried for the purpose; the fruit is much esteemed by some in the manufacture of a sort of wine, while the pith of the stem furnishes excellent pith balls for electrical experiments. The parsley-leaved elder (*S. laciniata*), an English variety, is one of the more ornamental species, and is often cultivated. It is one of

Sambucus laciniata.

the kinds most frequently used for medicinal purposes. The downy elder (*S. pubens*) has handsome flowers, of a greenish or purplish white, borne in thyrses-like spikes, and a scarlet fruit, fully ripe at the time *S. Canadensis* is in

blossom. There are two very variable species of elder indigenous to Great Britain; the *S. Canadensis* and *S. pubens* are the only species peculiar to North America; southern Europe has three species, and China one.

ELDON, John Scott, earl of, lord chancellor of England, born in Newcastle-upon-Tyne, June 4, 1751, died in London, Jan. 13, 1828. He became a fellow of University college, Oxford, in 1767, in 1771 gained a prize for an English prose essay, and in 1772 forfeited his fellowship by a runaway marriage. The forfeiture not taking effect for a year, he resumed his studies at Oxford with the intention of taking orders, if a living fell vacant during that period. This not having been the case, he devoted himself to the study of the law, removed to London in 1775, and entered the office of a conveyancer. He was called to the bar in 1776, and for several years attended the northern circuit without much success. In 1780-'81 he distinguished himself in the case of Ackroyd v. Smithson and in the Clitheroe election case, and his professional success was assured. His receipts ranged from £6,054 in 1785 to £10,557 in 1798. He was made king's counsel in 1783, and in the same year became a member of the house of commons, where he kept his seat till he entered the house of lords. He was knighted in 1788, and appointed solicitor general, and in 1793 attorney general, which office he held till 1799, conducting the state trials of 1794 against Horne Tooke, Hardy, and others. In 1799 he was appointed chief justice of the common pleas, created Baron Eldon of Eldon, and entered the house of lords. He proved a consummate common law judge. He became lord chancellor in 1801, and held the office for 26 years, with the exception of the time (1806-'7) during which it was filled by Erskine. As head of the court of chancery, though distinguished for his knowledge of the law and the acuteness and subtlety with which he applied it, he encumbered the court with arrears, and caused great prejudice to the suitors immediately interested by his delay in rendering his judgments. The language in which they were stated was also obscure; but the extreme care with which they were prepared gives them high value as precedents. In the cabinet he had great influence; and under George III. he was said to have sometimes used the great seal in the name of the king even when the king was suffering from mental incapacity. He took part in all important debates in the house of lords, vigorously supported tory principles, and was earnest in his opposition to parliamentary reform and to the Catholic emancipation bill. He was created Viscount Encombe and earl of Eldon in 1821.—See "The Public and Private Life of Lord Chancellor Eldon, with Selections from his Correspondence," by Horace Twiss (3 vols. 8vo, 1844), and "Lives of the Lord Chancellors," by Lord Campbell.

EL DORADO (Span., the golden), a country which, during the 16th and 17th centuries, and

to some extent during the 18th century, was supposed to lie somewhere in the new world. Men's imaginations were inflamed by the riches actually discovered in Mexico and Pern, and they conceived a belief that there was an undiscovered country in which gold was even more abundant. Many attempts were made to discover it. Orellana, the lieutenant of Pizarro, reported that he had obtained definite information in regard to it on his voyage down the Amazon in 1540-'41. He pretended to have visited Manoa, its capital, and to have seen there immense treasures of gold and jewels. Martinez, a Spaniard, asserted that he resided seven months in the country, and gave full particulars in regard to its ruler and inhabitants. The two expeditions of Sir Walter Raleigh to Guiana (1595 and 1617) were undertaken in quest of this country. The faith in its existence was so enduring that Spanish expeditions on the same errand took place even in the latter part of the 18th century.

EL DORADO, an E. county of California, drained by three forks of the American river and by the Cosummes; area, 1,872 sq. m.; pop. in 1870, 10,309, of whom 1,582 were Chinese. It is crossed by the Sierra Nevada. It is one of the richest mining counties in the state, and mining is the chief industry. Besides gold, rich copper ore and excellent marble are found. There is also considerable timber and tillable land. The Placerville and Sacramento Valley railroad terminates in the county. The chief productions in 1870 were 3,997 bushels of wheat, 8,642 of barley, 6,235 tons of hay, 215,530 lbs. of butter, 50,096 of wool, and 118,831 gallons of wine. There were 2,098 horses, 3,809 milch cows, 5,402 other cattle, 17,387 sheep, and 4,123 swine; 39 quartz mills for the production of gold, 21 saw mills, and 2 flour mills. Capital, Placerville.

ELEANOR OF AQUITAINE, queen of France and afterward of England, born about 1122, died about 1203. She was the eldest daughter and heiress of William IX., duke of Guienne or Aquitaine, and was married in 1137 to Prince Louis, who in the same year succeeded to the throne of France as Louis VII. She was a lover of poetry and art, and could not sympathize with her ascetic husband. She accompanied him on the second crusade to the Holy Land in 1147. At that time he complained of her preference for other men, and on their return from Asia they were divorced, March 18, 1152. A short time afterward she bestowed her hand upon Henry Plantagenet, the future Henry II. of England. This alliance, which made Henry master of Eleanor's possessions in France, produced protracted wars between the two countries. She bore him many children; but his infidelities and neglect having changed her love into hatred, she incited her sons Geoffrey and Richard to rebel against their father, was arrested in 1173, and remained in confinement until after Henry's death in 1189. She was released by his suc-

cessor, Richard I., Cœur de Lion, who placed her at the head of the government on his departure for the Holy Land. She negotiated his marriage with the daughter of the king of Navarre, and went to Germany with his ransom from captivity. She afterward retired to the abbey of Fontevrault, and surviving Richard, lived to see him succeeded by one of her other sons, John, the signer of Magna Charta.

ELEATIC SCHOOL, a group of Greek philosophers, beginning with Xenophanes of Colophon, who settled in Elea or Velia, a Greek colony of southern Italy, in the latter part of the 6th century B. C., and whose principal disciples were Parmenides and Zeno, both of Elea, and Melissus of Samos. Some of the ancients also ranked Leucippus and Empedocles among them, but for this there is no evidence. The general spirit of the school may be defined as an attempt, perhaps the first ever made, to refer all science to the absolute and pure ideas of the reason. There are, according to the Eleatics, two kinds of knowledge, that which comes to us through the senses, and that which we owe to the reason alone. The science which is composed of the former is only an illusion, for it contains nothing true, fixed, and durable. The only certain science is that which owes nothing to the senses, and all to the reason. Children and the untaught may believe in the reality of sensible appearances, but the philosopher who seeks the foundation of things should appeal only to the reason. There are two principles in nature, on the one side fire or light, and on the other night, or thick and heavy matter. These principles are distinct but not separate; they act in concert, playing together a perpetual and universal part in the world. The world is bounded by a circle of light as by a girdle, and is divided into three parts, in the central one of which necessity reigns supreme. The stars are but condensed fire, and the earth is the darkest and heaviest of all bodies. It is round, and placed by its own weight in the centre of the world. Men are born of the earth, warmed by the solar rays, and thought is a product of organization. From this commingling of fire and earth have begun all the things which our senses show us, and which will some time perish. But in all these physical phenomena there is no true science. Reason is the exclusive source of certainty, and reason conceives and recognizes as true nothing but absolute being, being in itself considered, that is, as disengaged from every particular, fleeting, and perishable circumstance, modification, or accident. Thus everything which has ever begun to be, everything which is susceptible of change or modification, of birth or destruction, has no veritable existence; it is not being, but only appearance. Besides being, in this sense of the word, there is, according to the Eleatics, only nothingness; and as this is but the negation of all things, one can neither affirm it nor deny it. Being is eter-

nal, unchangeable, self-existent; it has neither past nor future, neither parts nor limits, neither division nor succession; it is then an absolute unity, and everything else is but an illusion. Thus, the Eleatic system denies the data furnished by the senses, denies the generalizations and abstractions which the reason founds upon such data, and affirms only those necessary ideas which the reason owes solely to itself, and which it employs in its operations. The result is a pantheism, in Xenophanes resembling the blended material and spiritual pantheism of Spinoza, and in Parmenides approaching the spiritual idealistic pantheism of Fichte.

ELEAZAR (Heb., God is help), the name of several ancient Hebrews, of whom the following are the most important. **I.** The third son of Aaron, who held in his father's lifetime the oversight of the Levitical order, and on Aaron's death was raised to the dignity of high priest. His pontificate was contemporary with the military government of Joshua, and the book of Joshua closes with an account of his death and burial. **II.** One of David's three mighty men, who smote the Philistines till his hand was weary, and who with two others broke through the Philistine host to bring to David a draught of water from the well at Bethlehem.

ELECAMPANE (Fr. *énule campane*, from Lat. *inula campana*), the common name of the *inula helenium*, a handsome herb of the order *compositæ*, which, introduced into America from Europe, is now common in our gardens, and grows wild in meadows and by the roadsides in the northern states. The root should be dug in autumn and of the second year's growth. It has an agreeable aromatic odor

Elecampane (*Inula helenium*).

when dried, somewhat like that of camphor, and its taste when chewed is warm and bitter; water and alcohol extract its peculiar properties, the latter most readily. Its extracts afford the vegetable principles alantine or inuline, resembling starch, and helenine, which

forms long white crystals. The powdered root or the decoction in water is used in medicine as a tonic and stimulant. It is prescribed, if at all, in chronic diseases of the lungs. It is known in medicine by the name of inula. The dose of the powder is about a drachm; of the decoction one or two fluid ounces.

ELECTOR, or **Prince Elector** (Germ. *Kurfürst*), in the old German empire, the title of the princes who elected the emperor. The electoral privilege had its origin in the right assumed by the powerful nobles, who acquired supremacy in Germany after the extinction of the Carolingian dynasty, of choosing one from their own number to be their head. In the ordinance issued by the emperor Charles IV. in 1356, known as the "golden bull," the archbishops of Mentz, Treves, and Cologne, the count palatine, the duke of Saxony, the margrave of Brandenburg, and the king of Bohemia were recognized as the persons in whom this right was vested. These electors formed an electoral college, had the rank of king though without the title, and were possessed of various important rights and privileges. The electoral rights of the count palatine having been transferred during the thirty years' war (1623) to the duke of Bavaria, an additional or eighth electorate was created for the palatinate in 1648, which ceased to exist in 1777, when the house of Bavaria became extinct. Brunswick-Lüneburg was created an electorate in 1692. (See HANOVER.) When the left bank of the Rhine was ceded to France in 1801 by the treaty of Lunéville, changes in the electoral college became necessary, and were made in 1803. In place of the three ecclesiastics who were previously members of the college, the margrave of Baden, the landgrave of Hesse-Cassel, the duke of Würtemberg, the grand duke of Tuscany, who was also archbishop at first of Salzburg and afterward of Würzburg, and the archbishop of Mentz, with the style of archchancellor of the German empire, were confirmed in the electoral right. The whole electoral system, however, soon afterward (1806) came to an end upon the renunciation by the emperor Francis of the title of emperor of Germany. After that event most of the electors were designated by other titles. Hesse-Cassel ceased to be an electorate during the time it was merged in the new kingdom of Westphalia, but resumed the name upon the dissolution of that kingdom in 1813, and continued to be known by it until annexed to Prussia in 1866.—In the United States electors are chosen by the people of each state to elect the president and vice president. Each state chooses as many electors as it has members in the two houses of congress; and these electors meet at the capitals of their respective states, on the first Wednesday of December after the election, and cast their votes for president and vice president. These votes are then sealed up and carried by special messengers to Washington, where they are opened and counted before

both houses of congress, and the result proclaimed by the president of the senate.

ELECTORAL COMMISSION. See p. 806.

ELECTRA, daughter of Agamemnon and Clytemnestra, and sister of Orestes, Iphigenia, and Chrysothemis. The crimes of her mother and Ægisthus threw her into great distress. Fearing for the life of her younger brother Orestes, she sent him to King Strophilus of Phocis. When he was grown up to manhood, she instigated him to avenge their father's death, and became his accomplice in the murder of their mother. She subsequently married her brother's friend Pylades, and became the mother of Medon and Strophilus. Her tomb was shown in later times in Mycenæ. There are different versions of her story, which was used by the Attic dramatists Æschylus, Sophocles, and Euripides, the "Electra" of Sophocles being one of his most famous plays. It has also furnished a subject for Racine, Alfieri, and Goethe among the moderns.

ELECTRIC FISHES. The extraordinary modification of the peripheral extremities of nerves by which electricity is generated and discharged is found in four genera of fishes, and in no other class of the vertebrata. The best known of these fishes are the torpedo and the electrical eel; the former will be separately treated under its own name, and the latter, with two others for which there is no common name, in this article.—The electrical eel (*Gymnotus electricus*, Linn.), though apodal and eel-like in general appearance, differs from the eels in the completeness of the jaws, the presence of ribs, and the jointed fin rays; it has neither ventral nor dorsal fin; the anal reaches to the point of the tail, and like the pectorals is enveloped in a thick skin which conceals the rays; the skin is soft and scaleless; the head is oval and flat, the mouth furnished with broad lips, and opening not quite as far as under the eyes; the anterior nostrils are small tubes in a slight depression on the side of the

Electrical Eel (*Gymnotus electricus*).

lips; the posterior are behind and above them; lateral line distinct; about 50 pointed teeth on the upper jaw, and 60 on the lower, a second row of about six behind the middle of the upper ones, and four small teeth in two rows along the symphysis; the vent opens before the

branchial orifices, and behind it is a small opening and a slender papilla. The only species known inhabits the rivers of the northern parts of South America; it attains a length of 5 or 6 ft., and is brown and yellowish. The electric apparatus which has rendered this fish so celebrated occupies the space between the pectorals and the tail, for a large part of the lower bulk of the body; the organs are four in number, two on each side, the upper and larger organ being separated from the lower by a thin stratum of muscle and membrane, and the organs of one side are distinct from those of the other; the apparatus consists of an assemblage of membranous horizontal plates, nearly parallel and intersected by delicate vertical plates; the cells thus formed are filled with a glutinous matter; the septa, according to Hunter, are about $\frac{1}{10}$ of an inch from each other, and one inch in length contains 240 cells, giving a very great surface to the electric organs. The system is abundantly supplied with nerves from the

Malapterurus Electricus.

200 pairs of ventral spinal nerves, but not from the lateral continuation of the trigeminal and vagus nerves from which the electric system of the torpedo is supplied. The electric eel seems to be a mere appendage to the anterior part of its battery for moving it about, as all the other organs are confined to a very small space, even the vent opening under the head; and the nerves supplying the electric organs are much larger than those sent to any sensory or motor organs. According to Humboldt, the South American Indians capture these eels by driving horses and mules into the water inhabited by them; the electric powers of the fish being exhausted on the quadrupeds, the former are harpooned and thrown on shore; the horses suffer greatly, many of them being killed by the electric discharges of the fish which glide beneath their bodies. By grasping the head of the eel with one hand and the tail with the other, painful and almost insupportable shocks were received in the experiments of Faraday. This fish is neither voracious nor fierce, but uses its battery to secure its prey, and to defend itself

from its numerous enemies.—The third electrical fish belongs to the family of *siluridae*, and the genus *malapterurus* (Lacép.). The *M. electricus* (Lacép.) differs from the common siluroids in having no anterior dorsal fin nor pectoral spine; the skin is naked and scaleless; there is an adipose dorsal fin near the caudal; the ventrals are just behind the middle, and the anal occupies about half the distance between them and the rounded caudal; the body is stout, the tail thick, and the head short and conical; the lips are fleshy, with six barbels; five villiform teeth in each jaw, none on the vomer. The fish attains a length of 18 or 20 in., and is found in the Nile, Senegal, and other rivers of northern and central Africa; the color is cinereous or olive above, spotted and irregularly marked with black, whitish below; anterior nostrils tubular. The existence of a fish with benumbing powers in the Nile has been known for more than 300 years, but Geoffroy and Rudolphi were the first to give detailed descriptions of the electric organs. Valenciennes describes these as forming on each side of the body, between the skin and the muscles, two thin layers of spongy cellular tissue uniting together small lozenge-shaped cells filled with gelatinous fluid, and six or more fine longitudinal membranes; combining the structure of these organs in the torpedo and gymnotus, and receiving the nervous influence both from the lateral branch of the vagus and from the ventral branches of the spinal nerves. The shock given by this fish is comparatively feeble, the discharge taking place when the head is touched; no shock is felt when the tail is grasped, as the electric organs do not extend to this part; in giving a shock the tail is moved, as if the muscles were active. This fish is much esteemed as food. The Arabs call it *raash* (thunder).—The fourth electrical fish belongs to the order *plectognathi*, family *diodontidae*, and genus *tetraodon* (Cuv.). The upper and under jaws are divided by a median suture, so that they seem to have two teeth above and two below, incorporated with the jaws; in most of the species of the genus, the body, except the head and tail, is rendered rough by spines made erect by the inflation of the skin, or naturally erect; but in the electric species (*T. electricus*, Paterson) the skin is destitute of spines, in conformity with the ascertained law that no electric fishes have either scales or spines; the body is brown above, yellow on the sides, sea-green below, and varied with red, green, and white spots. It attains a length of 7 or 8 in., and is found in the lagoons of the Pacific. Its electric powers are comparatively feeble.—The most characteristic feature of all these batteries is their enormous supply of nervous matter; the electric organs generate the electricity, which is rendered active by nervous influence. In the torpedo the shock is best received when one hand is placed on the back and the other on the abdomen of

the fish; in the gymnotus the intensity of the shock is in proportion to the length of the fish included between the hands; actual contact with the torpedo is not essential, as it is well known by the Neapolitan fishermen that the shock is felt when the water is dashed upon it, the electric current passing up along the stream, the circuit being completed through the earth to the ventral surface of the fish; the dorsal surface is always positive, and the ventral negative. That this is the same as common electricity has been shown by Matteucci and Faraday; it renders the needle magnetic, and decomposes chemical compounds; by it heat is evolved, and the electric spark is obtained. The exciting nerves terminate in loops, as in the muscular tissue, and they arise like motor nerves from the anterior tract of the cord; the reception and conveyance of impressions, and the voluntary act which results in the shock, are of the same nature and follow the same course as the muscular contractions; a division of the electric nerves at their origin arrests all voluntary shocks, but an irritation of the ends of the nerves in connection with the organ is followed by an involuntary electric discharge, just as an irritation of the end of a divided motor nerve in connection with muscle is followed by its contraction. The electric like the muscular power is exhausted by exercise, and recovered by rest; both are increased by energetic respiration and circulation, and both are exalted by the action of strychnine, which produces tetanic contraction of the muscles, and a rapid succession of involuntary electric discharges. The phenomena displayed by these fishes afford no ground for the opinion that nervous influence is identical with electricity; the former is no more identical with the latter than it is with muscular contractility; the contractility of the muscle resides in its fibre, and the electricity is generated in the battery of the fish; both are brought into play through nervous influence, but neither resides in or is a property of the nerves. The phenomena of heat, electricity, and phosphorescence within the animal body depend on chemical actions, which take place in the system just as they would in the chemist's laboratory, modified always by the mysterious vital principle. According to Faraday, the shock of the electrical eel is equal to that of 15 Leyden jars of 3,500 square inches of surface.

ELECTRICITY, the science which treats of the peculiar phenomena of attraction and repulsion exhibited when friction and other mechanical forces are applied to bodies, and of certain effects which accompany chemical decomposition or other change of physical state; or the phenomena that arise from the relation which bodies may bear to terrestrial and other magnetic lines, particularly when these are undergoing change in quantity or direction. The general science includes statical and dynamical electricity, or electric force in a state of rest or of motion. The former, being

usually developed by friction, at least for experimental purposes, is often called frictional electricity. The latter may be developed by chemical action, by heat, magnetism, and other forces; but in whatever way produced, it is always in the form of currents, and exhibits a constant manifestation of power. Statical electricity may also be obtained by greatly increasing the intensity of dynamical electricity, as will be shown in the articles **GALVANISM** and **MAGNETO-ELECTRICITY**. This article will treat of frictional electricity, while dynamical electricity, so far as it relates to the development of currents by chemical action, will be treated in the article **GALVANISM**. That part of dynamical electricity which relates to the development of magnetism by electrical currents, and of the development of electrical currents by magnetism, will be treated under the heads **ELECTRO-MAGNETISM** and **MAGNETO-ELECTRICITY**. The development of electricity by heat will be treated in the article **THERMO-ELECTRICITY**.—The word electricity is derived from the Greek *ἤλεκτρον*, amber, a substance described by Thales of Miletus six centuries before Christ as possessing the property, when rubbed with a piece of silk, of attracting light bodies; this he ascribed to the presence of a soul, which when excited left the body and brought the light bodies to it. Theophrastus and Pliny mention the power of amber to attract straws and dry leaves, and also the possession of the same property by the *lapis lincurius*, supposed to be the mineral tourmaline. The electricity of the torpedo was known to the ancients, as we learn from Pliny and Aristotle; or rather, it was known that the fish had the power of producing certain physiological effects, but their explanation, or the relation which they bore to the property of amber, was unknown. As regards the science of electricity, a record of the simple phenomena of attraction and repulsion is all that has been handed down to us by them, and but little knowledge of the subject was acquired until toward the end of the 16th century, when Dr. Gilbert of Colchester, England, made a series of experiments on account of which he has been called the founder of the science. This title, however, can scarcely be justly applied to any one individual, especially at that early day, when a few isolated facts, as yet unconnected with any mathematical law, were all that was known. Robert Boyle, while investigating other physical subjects, added several substances to the list of "electrics." Otto von Guericke, about the same time or a little earlier, made discoveries of still greater scientific value; for instance, that of electrical induction. Sir Isaac Newton also made some important investigations in electricity, and Sir David Brewster ascribes to him the invention of the glass globe electrical machine. Stephen Gray, a member of the royal society, between the years 1720 and 1736 made several discoveries in regard to the conduction of electricity. M. Du Fay of the

French academy was perhaps the first to approach the subject in a theoretical way. He found that all bodies were susceptible of electrical excitement by friction if they were insulated, and was the first to propose the theory of two fluids, which he termed vitreous and resinous. The results of the labors of other investigators will be mentioned in the descriptions of apparatus or experiments. The discoveries of Franklin and some further notice of statical electricity will be found in the article **LIGHTNING**.—The ordinary phenomena of frictional electricity may be observed by taking a dry glass rod, rubbing it on a piece of dry silk, and presenting it to small scraps of paper or pieces of pith, when they will fly against the rod, and after remaining a short time, the length of which depends on the intimacy of contact and the nature of the light bodies, they will fly off with a sudden motion, as if repelled. Similar effects may be produced by using a stick of sealing wax, a material mainly composed of gum shellac, in place of the glass rod. It was supposed for a long time that only certain bodies were capable of becoming electrically excited, and they were called *electrics*, while those which did not distinctly manifest excitement under similar circumstances were called *non-electrics*. When the conduction of electricity was made the subject of investigation by Stephen Gray, it was found that all the so-called *electrics* were non-conductors, and that those which were termed *non-electrics* were conductors. This discovery led to the insulating of conductors and subjecting them to friction, when it was found that they also were readily excited. The division into *electrics* and *non-electrics* was thus found to be incorrect, and was abandoned, the fact being recognized that under proper circumstances all bodies are *electrics*. Bodies differ so greatly in the power of conducting electricity that they may be classed into conductors and non-conductors; but there are none which are perfect non-conductors except possibly dry gases. The following list of solids and liquids exhibits the conductors in the order of their conductivity, and the non-conductors in the inverse order, the best non-conductors being placed first:

CONDUCTORS.

All metals,	Snow,
Well burned charcoal,	Living vegetables,
Plumbago,	Flax,
Concentrated acids,	Hemp,
Dilute acids,	Living animals,
Saline solutions,	Flame,
Spring water,	Moist earth and stones.
Rain water,	

NON-CONDUCTORS.

Shellac,	Diamond,	Baked wood,
Amber,	Ebonite,	Porcelain,
Resins,	Gutta serena,	Marble,
Sulphur,	Silk,	Camphor,
Wax,	Wool,	Caoutchouc,
Jet,	Feathers,	Chalk,
Glass,	Dry paper	Oils,
Mica,	Leather,	Metallic oxides.

If an electrically excited insulated conductor is placed in contact with another conductor which is also insulated, a portion of its electricity disappears, and the two become equally excited. If the first body is large in proportion, it loses but little of its electricity; but if it be smaller than the other body, it parts with a proportional quantity; and if the difference is vast all sensible excitement disappears, as when communication is made with the earth, which is often called the common reservoir. Non-conductors may be used as insulators. Dry air is an excellent insulator; if it were not so, it would be impossible under ordinary circumstances to collect electricity upon any body, because it would be conveyed away as fast as generated. Damp air is a partial conductor, and therefore experiments in frictional electricity cannot be well performed during moist weather. It was for a long time observed that different bodies when electrically excited seemed to possess opposite states of electricity.

FIG. 1.—Attraction and Repulsion.

Thus, if a gilt pith ball be suspended by a silk thread, as in fig. 1, and approached by a glass rod which has been excited by friction with a piece of silk, it will be attracted to it; but as soon as contact is made it will be repelled, and the repulsion will continue as long as the ball retains its charge. If, however, a stick of excited sealing wax be brought toward it before its charge is lost, it will be attracted, and more powerfully than it was at first, by the glass rod. To explain this phenomenon different theories have been proposed, which are discussed in the article **ELECTRO-MAGNETISM**. In this article, for convenience of explanation, the existence of two fluids will be assumed, termed positive and negative, which in the natural state of bodies are supposed to be combined, but which are separated or decomposed by mechanical or some other force, and are moreover mutually attractive, but self-repulsive. There is no proof of a special electric fluid,

either compound or simple; but it may be that the luminiferous ether which most physicists now suppose to be the common medium for the transmission of light and heat will play an important part in a future theory of electricity. The fact that what is called the electric fluid cannot be discharged through a nearly perfect vacuum presents apparently a strong objection to the idea that the ether may be an electric medium; but this consideration does not affect the possibility that it may exert a controlling influence, and it is not improbable that the recent investigations into the molecular nature of bodies in relation to heat and light will lead to others by which the problem may at last be solved. With regard to the kinds of electricity which may be developed upon a body, it is found that it not only depends upon the body itself, but upon the body with which it is rubbed; thus, although glass in almost every instance collects positive electricity by friction, if the fur of the cat be used for this purpose it will be found to be negatively electrified. The surface also has much to do with the nature of the fluid which a given body may acquire; thus, if a piece of polished and a piece of rough glass be rubbed together, the former will be positively and the latter negatively electrified. If two silk ribbons are rubbed across each other, the one transversely rubbed will be negatively and the other positively electrified; and again, if two bodies of the same substance and having the same kind of surface, but differing in temperature, are rubbed together, negative electricity will be developed upon the warmer body. The kind of excitement a body may manifest also depends upon the color. When a piece of white is rubbed with a piece of black silk, the former acquires positive, and the latter negative electricity. The general deductions of Coulomb from numerous experiments are, that when two bodies are rubbed together, the one whose particles are least disturbed is more disposed to collect positive electricity. Other forms of mechanical action besides friction will develop statical electricity. Several minerals when pressed between the fingers exhibit free electricity. Calc spar, topaz, and fluor spar are examples, the first retaining its excitation for several days. According to the observations of Becquerel, the excitation is not perceptible while the pressure continues, but during the act of separation. Two similar bodies do not develop electricity when pressed together unless one is colder than the other, the colder body always becoming negative. Cleavage or the tearing asunder of laminae will produce electrical disturbance in minerals, card board, or other laminated bodies. Vibration develops electricity. A wire composed of iron and brass, connected with a galvanometer, on being made to vibrate so as to produce a musical sound, will cause a deflection of the needle. Statical electricity is also developed by heat; a familiar example is the attraction and repulsion

of ashes when tourmaline is placed in hot embers.—*Electrical Induction.* If a globe, C, fig. 2, supported upon an insulating pillar, and charged with positive electricity, be placed near one end of a cylinder, A B, also insulated, but not previously electrified, from which small gilt

FIG. 2.—Electrification by Induction.

pith balls are suspended, the latter will be seen to separate, the separation being greatest at the two ends, while at a place midway no excitement will be manifested. It will be found that that portion of the cylinder nearest the globe will have negative and the further end positive electricity, the amount in either case diminishing from the ends to the place between where there is no excitement. The greatest divergence of the pith balls will be upon the end nearest the globe, and the point of no excitement will be nearer this than the other end. If the globe is removed to a considerable distance from the cylinder, the latter will assume its natural state, the excitation having been caused simply by a separation by induction of the combined fluid upon the cylinder, and without any abstraction of either positive or negative fluid. If, however, while the globe is near the cylinder, the latter be placed in communication with the earth, the positive electricity which is repelled to the further end will escape, and a corresponding quantity of negative electricity will flow in the contrary direction to the cylinder, and, being attracted by the positive fluid of the globe, will increase the charge upon the end nearest it. Then, if communication with the earth be interrupted and the globe removed, the cylinder will be charged with negative electricity, which will manifest itself in the separation of the pith balls, the divergence being now equal along the whole length of the cylinder. If the experiment is made with two cylinders, placed end to end, they will both become excited by induction, the induced electricity of one causing induction in the other. In this manner a number of cylinders may be electrified, but the excitation will become feebler in proportion to the departure from the globe. The ordinary explanation includes the idea that the action takes place at a distance, the non-conducting medium

between the excited globe and the cylinder being disregarded; but according to the researches of Faraday, the molecules of this intervening medium, which is called a dielectric because the electric action is propagated through it, become alternately positively and negatively electrified. This condition he called polarization of the medium, and to exhibit it experimentally he placed small fragments of silk in a vessel of turpentine, in the opposite sides of which two conductors were placed. Upon charging one of these, and connecting the other with the ground, the particles of silk immediately placed themselves end to end, forming a continuous chain from one conductor to the other. The influence of the dielectric is also shown by placing a plate of shellac between the electrified globe and the cylinder, fig. 2, when the latter will manifest more excitement than before, the divergence of the pith balls increasing. By using different substances as dielectrics, it will be found that each exerts a specific influence, the relative amount of which Faraday has termed specific inductive capacity. An experiment of Matteucci supports Faraday's theory. Several thin plates of mica were placed closely together, the terminal ones having metallic coatings. While in a state of excitation by induction the plates were removed one by one, and found charged, on one side with positive and on the other with negative electricity. If a pith ball be suspended by a linen or cotton thread, it will be more strongly attracted by an excited body than if suspended by a silk thread, because the linen or cotton thread will allow the electricity which is of the same kind as that of the excited body to pass away from the ball, while it becomes fully charged with the opposite kind. The silk thread, however, prevents this, and only allows the fluid which is of the same kind as that of the excited body to pass to the further side of the ball.—*Electroscopes*. These are instruments used for the purpose of detecting the presence of free electricity, and also its nature. The pith balls represented in fig. 2 are electroscopes, but they possess little delicacy. A much more efficient apparatus is formed by two strips of gold leaf placed together and suspended by a conductor, as in Bennet's gold-leaf electroscope, fig. 3. It is protected by a glass cover, within which, at either side, project from the bottom two conductors for the purpose of preventing the rupture of the leaves if they should diverge rapidly from a strong charge. A body having only a small amount of electricity, upon being held near the knob of the conductor, causes induction and separation of the leaves. In order to ascertain the kind of electricity any excited body may have, it is first brought near the knob; this is then touched with the finger to bring it in communication with the earth, and thus permit the escape of the electricity which is of the same kind as that of the body to be tested. Then, while the excited body is near, the finger is

removed from the knob, the gold leaves and the conductor being thereby again insulated. The instrument is now charged with electricity of an opposite kind to that of the body, the presence of which is manifested by a divergence of the leaves. The body to be tested is

FIG. 3.—Bennet's Gold-leaf Electroscope.

now removed, and a glass rod that has been rubbed by a piece of silk is brought near the conductor. If the divergence of the leaves increases, it will indicate the presence of positive electricity, because the positive electricity of the glass repels that of the same kind from the knob to the leaves. If, on the contrary, the approach of the excited glass rods causes a diminution of divergence, it will show the presence of negative electricity, because it will be attracted from the leaves to the knob.—*Electrometers*. For the purpose of ascertaining the intensity with which a body is charged, and also the laws of electrical attraction, an instrument was invented by Coulomb, called Coulomb's torsion balance electrometer, represented in fig. 4. Its essential parts consist of a very fine metallic wire, weighing about one tenth of a grain to the foot, which is held in a cap at the top of the apparatus, and supports a delicate needle of shellac in a horizontal position at its lower end. This shellac needle has a small gilt ball, *g*, at one extremity, which being insulated may be made to receive, and for a short time to retain, a quantity of electricity. Another rod of shellac, *f'*, is so adjusted in the cover of the large glass cylinder that the small gilt ball *g'* which it carries, and which is of the same size as the ball *g*, may be passed down and held at a level with the latter. If now the horizontal needle *f* is so placed that the ball *g* may be touched by the ball *g'*, and the latter is charged with electricity and introduced, it will deliver to the former half of its charge, and the two will be mutually repelled, the repulsion being measured by the amount of torsion of the suspending wire, which may be ascertained by

means of a circular scale marked upon the circumference of the cylinder, and another suitably adjusted at the upper end of the small cylinder from which the wire is suspended. The cap at the top may be turned to increase the force of torsion, which is in proportion to the angle, and bring the balls nearer together; and it will be found that when the distance has been reduced to one half, the angle of torsion will be four times as great. It must be remembered, however, in making the calculation, that the actual distance between the balls is measured by the chord of the arc, and not by the arc itself. With this instrument Coulomb demonstrated the two following laws: 1. The force of attraction and repulsion between two electrified bodies is in the inverse ratio of the squares of their distance. 2. The distance remaining the same, the force of the attraction and repulsion between two electrified bodies

FIG. 4.—Coulomb's Torsion Balance Electrometer.

is directly as the product of the quantities of electricity with which they are charged. It is a natural conclusion that when a body is electrically excited, that is, when it contains free static electricity, it resides upon the surface, being held there by the resistance of the insulating air and the self-repulsion of the fluid; and such a conclusion is borne out by experiment; but in the case of currents the capacity of a body depends upon the area of its cross section, a hollow wire not being so good a conductor as a solid one. If a hollow, insulated globe, fig. 5, having an aperture, is charged with electricity, and a small disk of gilt paper, called a proof plane, is carried by means of an insulating handle into the globe and applied to its interior surface, it will be found upon withdrawal to contain no free electricity. Faraday used a wire-gauze cylinder in place of the globe. It rested upon an insulated metal plate, which being charged of course supplied electricity to

the cylinder, but it all resided upon the exterior, no trace being found on applying the proof plane to the interior. Coulomb's torsion electrometer may also be used to demonstrate the same condition; for if a solid and a hollow sphere of the same diameter be brought

FIG. 5.—Proof Plane and Hollow Sphere.

together, one having free electricity, the charge will be equally divided between them. In consequence of the self-repelling force of the electric fluid which thus causes it to reside upon the exterior of bodies, it will be distributed in equal quantities over the surface of a sphere; but upon an ellipsoid or an elongated cylinder it will be greatest at the ends, and if these be quite acute the tension will become so great as to cause it to be discharged in a current. A disk also contains nearly all the charge at the circumference, as may be shown by the use of the proof plane and Coulomb's torsion electrometer, substituting the proof plane in place of the gilt ball in the carrying rod. An exception to the rule that static electricity is confined to the exterior of a body is when an insulated electrically excited body is placed in the interior of a hollow conductor. In this case the excited body will induce upon the interior surface of the conductor a charge of opposite electricity; and if the conductor be insulated, an equal quantity of the same kind will be repelled to the outside. Again, if a conducting body be suspended by a wire connected with the earth inside of a hollow, charged, insulated conductor, it will become charged by induction with electricity opposite to that of the hollow conductor, a part of the charge of the latter being at the same time brought to its inner surface also by induction. If, now, the inner body be insulated and lifted out by a silk thread attached to the wire, it will retain its charge of opposite

electricity to that of the hollow conductor, but the electricity which existed upon the internal surface of the latter while the conducting body was inside will now return to its external surface. In fact, the two bodies are related to each other in a manner similar to the conductor and cylinder in fig. 2, so that the exception to the rule is more apparent than real. An electrified insulated body after a time loses its electricity; this is called dissipation of charge, and takes place partly along the supports and partly through the air. Coulomb found that, other circumstances remaining the same, the rate of loss is simply proportional to the charge, so that at equal intervals of time the charges form a decreasing geometrical series, following a law similar to Newton's law of cooling.—*Electrical Machines.* The first electrical machine was invented by Otto von Guericke, who was also the inventor of the air pump. A ball of sulphur turned on an axis was electrified by friction with the hand, receiving negative electricity, while the positive flowed to the earth through the person. Sulphur was afterward replaced by resin, and for this the English philosopher Hawksbee substituted a cylinder of glass. The hand was used as a rubber in all these, the cushion rubber made of horsehair, covered with silk, being introduced by Winckler in 1740. About the same time it is said that Boze, another German philosopher, used an insulated cylinder of tin. In 1760 Ramsden replaced the glass cylinder by a circular glass plate. Fig. 6 is a modification of Ramsden's machine in use at the present time. Between the two supports in which the glass wheel turns, and near its upper and lower edges, are two pairs of cushions, usually made of leather stuffed with horsehair and

FIG. 6.—Ramsden's Plate Electrical Machine.

coated with bisulphide of tin or some amalgam, mixed with grease, as Kienmier's amalgam, which is composed of one part of zinc, one of tin, and two of mercury. These cushions are the rubbers for producing friction, and are con-

nected with the earth by means of a metal chain or rod. Two large hollow cylinders of brass, C C, with globular ends, each supported by two glass pillars, constitute the reservoir for receiving the electricity, which in this case is positive. They are called the prime conductors, and are supplied with U-shaped rods of metal, furnished with points along their sides called combs, for the purpose of receiving the electricity from the glass plate, the arms of the U being held upon either side. The other ends of the conductors are connected by a rod, r , from the middle of which projects another short rod terminating in a knob for delivering the spark. The action of the machine is as follows: When the plate is turned friction decomposes the fluid, positive electricity going to the glass and negative to the rubbers. The positive electricity of the plate attracted by the combs, passes to the prime conductor, while the negative upon the latter passes in a contrary direction to the plate, which in turn delivers it to the rubbers. The rubbers in consequence of their connection with the earth, receive positive electricity, which is powerfully attracted by the negative they contain, the union being again destroyed by friction and the positive fluid delivered to the prime conductor, where it collects until the tension becomes greater than the confining force of the air. It is then spontaneously discharged in sparks and jets, with a crackling and hissing noise, unless taken off by a conducting body. Upon the two-fluid theory it is supposed that as much of negative fluid passes in one direction as of positive in the opposite; so that a body always contains the same amount of electricity, either of one or of both kinds. Some machines, like that of Prof. Nairne, which employs a glass cylinder, are constructed with two conductors, one connected with the rubbers and the other with the points which receive the fluid from the cylinder. By connecting the positive conductor with the earth, and insulating the rubbers, negative electricity may be obtained. A convenient method is to mount the prime conductor upon an independent stand, and connect it at pleasure either with the points or with the rubbers. A great variety of forms of machines may be constructed, and the prime conductors may be made to receive their charge either by conduction from the plate or rubbers, or by induction. Of the latter kind, one invented by Holtz of Berlin, in 1865, remarkable for its great power, is represented in fig. 7. A circular glass plate, a , is fixed in an insulating frame. In opposite sides, near the circumference, are two large orifices, which are partly covered at the back by two bands or armatures of thick paper, f, f' , having points projecting in the opposite direction to that of the motion of a second glass plate, b , somewhat smaller than a , and made to revolve very near it. Opposite the face of the movable plate, which has no orifices, there are metal combs, p, p' , con-

nected with insulated conductors which terminate in adjustable knobs, *m* and *n*. An orifice in the centre of the fixed plate gives passage to the axis of the movable one, which can be rapidly rotated by a system of band wheels. The machine is started by bringing the knobs *m* and *n* of the conductors together and elec-

FIG. 7.—Holtz's Electrical Machine.

trifying one of the armatures, say *f*, by holding against it a plate of ebonite which has been negatively excited. After a few turns of the plate both armatures become highly charged with opposite kinds of electricity, *f*' becoming positive, and if the knobs are separated a stream of sparks will pass from one to the other. By increasing, within a certain limit, the distance between the knobs, the sparks become larger and less frequent; but beyond this limit, which depends upon the insulation and working order of the machine, the sparks will no longer pass, and unless the knobs are quickly brought together the machine will cease to act. The following is a brief explanation of its action. The negative electricity of the first armature tends to repel the same fluid in its vicinity, and to attract the opposite; consequently negative electricity flows from the face of the movable plate to the points of the comb, while positive electricity is discharged by the comb upon the plate. This will cause the comb of the second conductor, which at the commencement, as has been said, is in connection with the first, to become negative, while each portion of the glass plate will pass from the first to the second comb positively electrified. When successive portions of the plate thus charged arrive opposite the second armature, the latter, through its point, discharges negative electricity upon the plate and receives positive in return, thus becoming positively charged. Positive electricity from the face of the plate also passes to the second comb, and the latter discharges negative electricity upon the plate, which then passes on to the first armature and comb negatively electrified. Therefore the comb will dis-

charge positive electricity on and receive negative from the plate, and the armature will also receive a higher negative charge from the other side of the plate, because the latter is charged with higher tension. The effect is to cause the plate to leave the first comb more highly positive than it was the first time, and on again coming opposite the second armature to increase its positive charge. Both armatures become thus in a short time highly charged with opposite electricities, whose tension is only limited by the degree of insulation. A strong current of positive electricity, it will therefore be seen, is constantly passing through the conductors from the second to the first comb, and a corresponding current of negative electricity from the first to the second comb; and when the knobs of the conductors are separated the electricity will leap from one to the other. It is moreover evident that the action of the machine requires that each part of the movable plate be charged with electricity of an opposite kind to that of the armature it leaves, and of the same kind to that of the one it approaches. This condition, however, cannot continue if the conductors are so far separated as to prevent communication, or are beyond striking distance, because there would then simply be two armatures in opposite electrical conditions, with a moving plate passing from one to the other and gradually equalizing the charge. The inventor has recently modified this machine by placing the plates horizontally and turning them in opposite directions, as represented in fig. 8. Neither plate has openings, but two combs are placed above the upper plate opposite each other, and two others below the lower plate, at right angles to the upper ones. Each of the upper

FIG. 8.—Holtz's Machine with Horizontal Plates.

conductors is connected with one of the lower, so that there are only two conductors. The machine is started by holding for a short time an excited plate of ebonite opposite one of the combs. Sometimes, as in the figure, a third

upper comb is placed above one of the lower combs, which appears to increase the power. In both forms of the machine work is expended in turning the plates in opposition to electrical attractions and repulsions, by which mechanical is converted into electrical energy. It will always be found difficult to obtain good results with electrical machines in damp weather. By warming the glass insulators, however, and frequently rubbing them with a warm dry cloth, their non-conducting property may be in a degree preserved. The Holtz machine is more sensitive to moisture than the ordinary kinds.—Other apparatus besides the ordinary machine are employed to develop static electricity, the electrophorus of Volta being used with advantage in some experiments. It usually consists of a cake of resin about 1 in. thick, represented in fig. 9, resting upon a metallic base called the sole, and having resting upon it a metal disk with a rounded edge, and of less diameter than the resinous cake, furnished with an insulating handle. A good material for the resinous cake is composed of ten parts of shellac and one of Venice turpentine. Resin is better than glass or ebonite, because it does

FIG. 9.—Electrophorus.

not so readily condense moisture on its surface, and this little instrument requires to be in excellent condition to yield satisfactory results. In making experiments with the electrophorus the resinous cake is whipped with a catskin or rubbed with fur, which excites it negatively, and the metal disk is then laid upon it; this therefore has its natural fluid decomposed, the positive being drawn to the under and the negative repelled to the upper surface. The disk is now touched with the finger, by which it becomes positively charged from the earth, and if removed by the insulating handle will yield a spark; an operation which may be repeated several times before the resinous cake loses its charge.—The hydro-electric machine of Sir William Armstrong, which is said to have been discovered by accident, consists of a wrought-iron plate boiler, fig. 10, standing upon four glass legs. It is about 5 ft. long by 2 ft. in diameter, provided with a gauge, O, to show the height of water. A stopcock, C, when opened allows the steam to pass through a number of tubes in the box B,

containing cold water for cooling the steam. The ends of the tubes are furnished with jets whose construction is such as to increase the friction, and the jets are lined with hard wood, as shown in the figure at M. A metal plate, P, armed with points, collects the electricity, which is ordinarily positive, and conveys it to the prime conductor, D. There

FIG. 10.—Sir William Armstrong's Hydro-electric Machine.

should be a pressure of several atmospheres in the boiler, and the water should be pure, the presence of a saline solution in the escape tube being sufficient to prevent development of electricity. By changing the material of which the jets are made the kind of electricity may be varied. If a small quantity of oil of turpentine is introduced into the boiler, the steam will become negatively and the boiler positively electrified. The generation of electricity by this machine was at first attributed to condensation of steam, but Faraday showed that it was caused by the friction of minute globules of water passing through the jets. Experiments are made with the ordinary glass-plate machine, represented in fig. 6, in the following manner: Let the rubbers be connected with the earth, the surface of the machine, especially the insulating supports, having been well rubbed with a warm dry cloth. If now the glass plate is turned briskly by the winch, on presenting a knuckle to the prime conductor induction takes place, the knuckle becoming charged with negative electricity. As soon as the tension is sufficient to overcome the resistance of the air, the fluids combine with a sharp report and a spark, a stinging sensation being felt in the knuckle. The spark will be

seen to better advantage if the room is darkened. By employing a hollow metal globe five or six inches in diameter, held by a glass handle, longer sparks may be obtained, as a greater quantity of negative electricity will be retained upon it before this discharge takes place. When the distance is short the spark is usually straight; when greater, it becomes curved, with branches or forks; and when considerable, say a foot, in large machines, it takes a zigzag course like that of lightning. When the air is dry and the machine working well, a hissing sound is heard, and in the dark luminous brushes are seen to issue from projecting parts of the conductor, and it will be found that the escape of positive electricity gives larger brushes than negative. Brilliant sparks will often leap across the plate

FIG. 11.—Spark in Rarefied Air.

between the cushions and the conductor, when the fluid is not otherwise taken away. By passing the spark through rarefied air and other gases various pleasing and curious effects are obtained. An apparatus called the electric egg, fig. 11, is often employed for this purpose. It consists of a glass globe with a cap at either end, through which passes a metal rod with a knob upon the interior extremity. The upper rod is made to slide so that the distance between the two knobs can be regulated at pleasure. Through the lower there is an opening provided with a stopcock, which may be screwed to a stand or to the plate of an air pump. When the egg is filled with air the spark has the ordinary appearance, but when partially exhausted it passes more readily, generally presenting the form given in the figure, the negative knob being usually surrounded by a violet halo, while the positive one exhibits a purple or a deep crimson. As the air becomes more rarefied the resistance to the discharge diminishes, and the brilliancy of the spark decreases, unless a nearly perfect vacuum is obtained, when no discharge will take place, as has been shown by Gassiot. These experiments are advantageously performed with the Holtz machine

by connecting the two poles with the two knobs of the egg, or other apparatus. The color of the spark depends on the gaseous medium and on the material of the conductors. When the spark is strong a portion of the conductor appears to be volatilized, from the fact that examination with the spectroscope reveals bright lines denoting the presence of metallic vapor, which are characteristic. When the spark is weak the influence of the gaseous medium is readily observed, nitrogen producing a blue, hydrogen a red, and carbonic acid a green color. The old electricians devised many pieces of apparatus for making curious and pleasing experiments, such as tubes, globes, and plates of glass, having small disks of tin foil placed at regular distances, distributed in spiral and other forms, so that when a spark was passed through the system it would be multiplied and exhibit illuminated figures. A person standing upon an insulated stool, and connected with the prime conductor, will become electrically excited, and sparks may be taken from the face or hands, or through the clothing, the resistance offered by the latter often causing the discharge to be quite loud and attended with a smart sting. The hair of the insulated person, if not too long, will stand upon end, and if dry each hair will be separate. A set of radiating arms like the spokes of a wheel, having their points bent in one direction, balanced upon an upright pointed rod supported by the prime conductor, fig. 12, will revolve when the machine is in action; an effect caused by the repulsion between the electricity of the points and that of the adjacent air which has been charged by them. A point placed upon the conductor, as in fig. 13, will create a current of air which may be felt by the hand or made manifest by placing a candle before it.—A phenomenon usually accompanying the passage of a stream of electricity from a point, or of the spark, is the conversion of a portion of atmospheric oxygen into its allotropic condition, ozone, which is easily perceived by the sense of smell. The conversion is supposed to be

FIG. 12.—Revolving Points.

FIG. 13.—Current shown by means of a Flame.

the passage of a stream of electricity from a point, or of the spark, is the conversion of a portion of atmospheric oxygen into its allotropic condition, ozone, which is easily perceived by the sense of smell. The conversion is supposed to be

produced by a rearrangement of the atoms of the oxygen molecules in consequence of vibrations communicated by the electric force.—*Duration of Spark.* The duration of the electric spark was measured by Wheatstone in 1835 by means of a rotating mirror. Let m , n ,

FIG. 14.—Duration of Spark.

fig. 14, represent a section of a mirror revolving on an axis c . A spark at a will be seen from o in the position of a' when the surface of the mirror is in the plane $e e'$, and in the position a'' when the surface of the mirror is in the plane $t t'$. An instantaneous spark would appear as a point; that it has duration is proved by its having the appearance of a line. Wheatstone estimated this duration to

FIG. 15.—Condenser.

FIG. 16.—Leyden Jar.

be $\frac{1}{24,000}$ of a second. Experiments afterward made by Feddersen, and published in 1858, showed that the spark when analyzed consisted of two parts, viz., a whitish streak and a red tail; and that, exclusive of the red tail, it was prolonged by increasing the charge, and also the area of the coating. A further and more careful analysis of the spark from a Leyden jar, connected with a Ruhmkorff coil, has recently been made by Prof. O. N. Rood of Columbia college, in which he found the duration varied with the substance of the electrodes, and also with the striking distance and the area of coating. By the use of nicely adjusted apparatus he succeeded in producing sparks from platinum electrodes at a distance of one millimetre, whose duration was ascertained to be a little more than 41 billionths of a second.

An account of the experiments may be found in the "American Journal of Science" for September, 1869, September, 1871, and September, 1872.—*Condensers.* The condensation of electricity is usually effected by separating two conductors by a plate of glass or other non-conductor, and connecting one of them with the earth in the manner shown in fig. 15. A plate of glass or other non-conductor employed in this manner is called a dielectric. On bringing the insulated conductor in connection with an electrified body, as the prime conductor it becomes charged with one kind of electricity, while the conductor on the other side of the plate becomes charged with the opposite kind, drawn from the earth and held by the powerful attraction exerted through the non-conductor, or dielectric. Charges of enormous intensity may be obtained by these means. The Leyden jar, fig. 16, said to have been in-

FIG. 17.—Puncture of Card.

vented by Cuneus, a pupil of Musschenbroek of Leyden, in 1746, is constructed upon this principle. It consists of a glass jar coated with tin foil upon both inner and outer sides to the same height, space enough being left to avoid union of the opposite fluids across the edge. To the mouth is fitted a cover of baked wood, through which passes a rod carrying a chain which lies upon the inner coating, and having a knob upon its upper end by means of which connection between the outer and inner coatings may be readily made by a jointed discharger provided with a glass handle. The Leyden jar is advantageously used in making experiments requiring great intensity of charge. Its condensing capacity depends, within certain limits, upon the thickness of the glass, it being in the inverse proportion of the distance between the two coatings, and upon the extent of their surface. Its power may there-

fore be increased by placing a number of jars together on a sheet of tin foil or other good conductor, and connecting all the inner coatings by rods or chains passing from knob to knob. Such an apparatus is called a Leyden battery, and it may be charged, like a single jar, with the ordinary machine, by connecting one coating, it is not very material which, with the prime conductor, and the other with the earth or with the rubbers. In charging with the Holtz machine, one conductor is connected with the inner and the other with the outer coating. If a piece of card board is placed between two points, as in fig. 17, and one of them, say the lower, is connected with the outer coating of a charged Leyden jar, on bringing the knob of the jar near the knob connected with the upper point, the fluid will leap across the spaces between the knobs as well as between the points, but in passing from point to point it will pierce the card board. The hole will be found burrowed on both sides in consequence of the repulsion of the particles of paper, and its location is also nearer the negative than the positive point, unless placed in an exhausted receiver, when it will be nearer the middle. By using a battery of several jars the fluid may be made to pierce a hole through a thin plate of glass. It may be remarked that if the experiment fails the first time, subsequent ones with the same piece of glass will scarcely succeed as the fluid will almost invariably follow the course it first took. Gunpowder, turpentine, and combustible gases may be fired by means of the Leyden jar or battery, and metallic wires may be fused if they are small enough to offer sufficient resistance to the passage of the fluid. After a Leyden jar is discharged, if a short time is allowed to elapse, and the coatings be again brought near together, a second or a third smaller spark may be obtained. The electricity thus remaining after the first discharge is called the residual charge, and, according to Faraday's experiments, it is caused by the gradual penetra-

Fig. 18.—Lane's Unit Jar.

tion of the electric fluid into the substance of the glass dielectric, and accords with his opinion that conductors differ only in degree. The charge of a Leyden jar or battery may be estimated by means of an apparatus called a unit jar. Lane's unit jar or electrometer is represented in fig. 18. The jar or battery whose charge is to

be measured is placed upon an insulated stand, and the inner coating connected with the prime conductor. If no connection were made between the external coating and the earth, it is evident that the jar could not be charged. The connection is made through a small Leyden jar, *c*, whose inner coating is connected with the outer coating of the first jar or battery, while its outer coating is connected with a rod carrying a knob, which is brought near to the knob connected with the inner coating. When the small jar becomes sufficiently charged the fluid will leap across the space between the two knobs, which is called the striking distance, the amount being quite uniform for the same distance, and called the unit of measurement. By using the same instrument similarly adjusted a comparison of charges of different batteries, or of the same battery at different times, may be made. The physiological effects of the discharge of a Leyden jar are similar to those of lightning. A small jar of only a few inches surface is capable of giving a powerful shock when passed through the arms, and a large jar or a battery strongly charged is capable of giving a shock sufficient to produce death.—Frictional electricity is sometimes used in medicine, and it may often be employed with advantage, either by passing small repeated shocks by means of a small unit jar through the body or limbs, or the patient may be insulated and have sparks drawn from him; but the galvanic battery, employed alone or with electro-magnetic currents, may generally be used with more certain results. The subject will be noticed in the article MEDICAL ELECTRICITY.—Among the numerous works that have been published on electricity are the following: *Æpinus, Tentamen Theoriæ Electricitatis et Magnetismi* (4to, St. Petersburg, 1759); Franklin, "Experiments and Observations on Electricity, made at Philadelphia in America" (London, 1769); Haüy, *Exposition raisonnée de la théorie de l'électricité et du magnétisme* (Paris, 1787); Tiberius Cavallo, "A Complete Treatise on Electricity" (3 vols. 8vo, London, 1795); Faraday, "Experimental Researches in Electricity" (London, 1849-'55); Sir W. Snow Harris, "Electricity, Magnetism, and Galvanism" (London, 1867); Deschanel, "Natural Philosophy" (New York, 1873); Ganot, "Physics" (New York, 1873); Fleeming Jenkin, "Electricity and Magnetism" (New York, 1873); J. Clerk Maxwell, "Electricity and Magnetism" (London, 1873).

ELECTRIC LIGHT, the light produced by a current of electricity in passing through a resisting medium, as a gas or a small wire. Like solar light, it also produces the combination of chlorine and hydrogen, acts chemically on chloride of silver in the photographic process, and when viewed through a slit in a screen by a prism it presents a spectrum crossed by very bright lines, differing in character with the substance of which the electrodes are formed, and with the gases through which

the sparks are passed. Hence the electric light becomes an important means of chemical analysis. With carbon the lines are remarkable for number and brilliancy; with silver they are intensely green; with lead, of a violet tint; and so on, varying with each different substance. Being producible in nitrogen, the electric light is not the effect of combustion, but of the intense heating and volatilization of ponderable matter. We say ponderable matter, because the electric spark cannot pass through a vacuum. A most intense and steady electric light is evolved be-

Duboscq's Regulator.

tween two points of coke, forming the poles of a battery, and brought into close proximity. From its great brilliancy and cheapness this light would seem to be well adapted for illumination, especially for lighthouses, and if introduced into mines it would apparently prove the most powerful illuminating agent, without tending, like other lights, to contaminate the purity of the air. But this light is deficient in the most penetrating ray of the spectrum, the red, and therefore does not produce the effect which was anticipated from it in the way of

penetrating fog. It is also so very intense, a large quantity of radiation being given off from a single point, that the eye is dazzled, and vision becomes much more indistinct than with the same quantity of light given off from a lamp with large concentric wicks. It may however be used with much success in various optical experiments. But in this application one of the principal obstacles to be overcome is the continual separation of the charcoal or coke points as these are slowly consumed. Caution is required in experimenting with this light when of great intensity; a single moment of exposure to the radiation from a battery of 600 couples produces violent headache and inflammation of the eyes. For the purpose of illumination it is necessary to have the light constant and uniform. The galvanic current as well as the distance between the carbon points must not change; and as the carbon slowly wears away, an apparatus is required to move them toward each other. The engraving represents Duboscq's regulator. Both the points move, but with unequal velocities, so as to keep the light at a fixed point, the positive point wearing away twice as fast as the negative. The motion is produced by a coiled spring in the drum placed on the axis $x y$. This turns two wheels, a and b , which move the racks C and C' , and by these the carbon points, one up and the other down. The current passes into the apparatus by the wire E and leaves it by E' , without however passing through the rackwork, which is insulated. Before leaving it passes through the coil B , surrounding a piece of soft iron, which is a magnet while the current passes, and constitutes the regulator. When the carbon points approach too near the strength of the magnet is increased, and by means of a lever the rod d is made to turn so as to stop the motion of a series of toothed wheels which are moved by the drum. Thus the motion of the points is arrested until they have wasted enough to diminish the current, and consequently the strength of the magnet, when the stop is relieved, and the motion continues. (See p. 808.)

ELECTRO-MAGNETISM, that science which treats of the development of magnetism by means of voltaic electricity. In our article on electricity we have given an exposition of the facts of this branch of science, independent of any hypothesis as to the causes of the phenomena; but the present topic cannot be treated satisfactorily without giving some idea of the generalizations which have been invented to explain the phenomena, and to express the laws of their mutual connection and dependence. It must be recollected that science does not consist in an accumulation of facts, but in a knowledge of principles, and it is impossible to arrive at a full comprehension of these principles without expressing them by means of some hypothesis from which logical deductions can be made, which will enable us at any time, independently of mere memory, to

say what result will be produced when the conditions are known, or in other words, which will not only present to us the relations of known phenomena, but enable us also to predict the occurrence of those which have not been observed. Without hypotheses of this kind no extended and definite progress can be made in science. It should, however, always be borne in mind that they are the provisional expressions of the generalizations of our knowledge at a given time, and that we must hold ourselves in readiness to modify or even abandon them when we meet with facts with which they are decidedly inconsistent. Two hypotheses have been proposed to account for the phenomena of electricity: one, that of Du Fay, known by the name of the theory of two fluids, and the other by that of the Franklinian, of one fluid. According to the first, all bodies are pervaded by two elastic fluids, the atoms of each repelling those of the same kind and attracting those of the opposite kind. When the two fluids are together in equal quantities in the same body, they neutralize each other; but when separated by friction or other means, their attractions and repulsions are manifested by various electrical phenomena. The second hypothesis supposes that all the electrical phenomena are produced by the disturbance of one highly elastic fluid, which pervades the earth and all material bodies, and which is able to move with various degrees of facility or not at all through the pores of substances of different kinds of gross matter, which are hence considered either conductors or non-conductors; that the atoms of this fluid repel each other with a force varying inversely as the square of the distance; that the atoms of the same fluid attract the atoms of gross matter, or some ingredients in it, with a force varying in accordance with the same law; and that the atoms of gross matter devoid of electricity tend to repel each other with a force inversely as the square of the distance. When any body has so much electricity combined with it that the self-repulsion of its atoms is just balanced by the attraction of the same atoms for the unsaturated matter, then the body is said to be in its natural state. So long therefore as all portions of space contain their natural share of the fluid, no electrical phenomena are exhibited; but if, by means of friction, chemical action, heat, or other agencies, together with the interposition of partial or non-conducting substances, the electricity is accumulated in one portion of space, and rendered to the same amount deficient in another, then two classes of phenomena are manifested: 1, those called statical, such as induction and the consequent attraction and repulsion of light bodies, due merely to the accumulation or deficiency of the fluid; 2, dynamical, or those which arise from the transfer of the fluid from the place where it is redundant to that where it is deficient. Franklin's claims to philosophic genius rest particularly upon his con-

ception of this theory of electricity, which, with slight modifications and additions, is still sufficient to express the connection and relation of the multiplicity of facts which have been discovered since his day. However different the two theories at first sight may appear, their mathematical expression and the deductions from them do not differ, provided that we adopt the modification of the latter proposed by Æpinus and Cavendish, that matter devoid of electricity repels matter; an assumption not inconsistent with the attraction of gravitation and chemical action, since we may refer even these to the same cause. The theory of Du Fay was generally adopted by German and French savants, because it was first discussed by them in a mathematical form. The theory of Franklin was afterward developed mathematically, and with the modifications we have mentioned is, we think, more readily applicable to the facts of the present state of the science than the other. It follows from the theory of Franklin that if electricity be communicated to a sphere of conducting matter, all the fluid will be found at the surface, because each atom repels the other, and the state of equilibrium will be that of an equal distribution at the circumference; the atoms are prevented from flying into space by the non-conducting medium of air in which the globe exists. In like manner it follows from an application of the law of attraction inversely as the square of the distance, that when a body has less than its natural share of electricity the deficiency must exist at the surface. In charged conductors of elongated forms, the distribution of the fluid will be greater at the two extremities. The phenomena of the Leyden jar are readily deduced, and all the facts connected with it may be anticipated even with numerical exactness, by the application of this theory. When a redundancy of electricity is thrown on one side of a pane of glass, the repulsion acting through the glass will drive off a portion of the natural electricity on the other side, the unsaturated matter of which will attract the free electricity thrown on the first side and thus neutralize its repulsive energy; and in this way an immense amount of electricity can be accumulated in a small space. When the two surfaces are joined by a conducting circuit a discharge takes place with great intensity, because the fluid on the charged side is impelled through the circuit by the repulsion of its own atoms, and because it is attracted to the other side by the unsaturated matter. If an insulated conductor in the form of a long cylinder with round ends be brought near a charged conductor, but not within striking distance, the natural electricity of the former will be repelled to the further end; the end nearer the charged body will be in a state of deficiency of electricity, or negatively electrified, while the further end will be in a state of redundancy, or positively electrified. Between the two ends there will be a point which will be neutral or

in its natural state. The intensity of this action diminishes rapidly with the distance, particularly in the case where the cylindrical conductor is short and the excited body is small; but in the case of atmospherical electricity, in which the charge is on the surface of a large cloud, the inductive action takes place through several miles of intervening space. An attempt was made by Laplace, Poisson, and others, to apply the same hypothesis to the phenomena of magnetism. Between these and those of electricity a striking analogy was observed. For example, bodies which are dissimilarly electrified attract each other; those which are similarly electrified repel each other. In like manner, two similar poles of a magnet repel, and two dissimilar poles attract each other. Again, if the north pole of a magnet be brought near an unmagnetized bar of soft iron, the near end exhibits southern polarity and the further end northern polarity, apparently similar to the result of the action in the example we have just given of electrical induction. There is however this remarkable difference, that if we magnetize a piece of hardened steel in the same way by the induction of a powerful magnet, and afterward break the bar into two pieces, each half will exhibit a north and south pole of equal intensity; and if we continue to break each piece into two others, however far the division may be continued, the same result will be produced, namely, a pole at each end of each piece and a neutral point in the middle. From this experiment we infer that the polarity of magnetism results from the development of the magnetic power in each atom of the mass; while if the same experiment be made with an electrical conductor, that is, if it be separated into two parts while under the influence of the excited body, each half will exhibit a charge of only one kind of electricity. By considering therefore that electrical induction is produced by a bodily transfer of fluid from one end of the conductor to the other, and limiting the disturbance in magnetism to the particles of gross matter, a mathematical expression of most of the phenomena known previous to the discovery of Oersted was obtained. Still electricity and magnetism were so dissimilar in some particulars that they continued to be studied as distinct branches of science. The fact had long been noticed that discharges of lightning frequently gave polarity to bars of steel, and in some cases reversed the mariner's compass. A series of experiments to imitate these effects were made by Franklin and others by passing shocks through darning needles. The results were unsatisfactory, since the needle was sometimes magnetized in one direction and sometimes in the other, and frequently not at all, without any apparent change in the conditions. Indeed, ordinary electricity was not favorable to the study of the connection of electricity and magnetism, since the phenomena which belong to both are exhibited during the continuance of

an electrical current; and in the case of the discharge of a Leyden jar the transfer is so instantaneous that we are only able to study effects which have taken place, without being able to make any observations as to the manner in which they have been produced. This was the condition of the science up to the winter of 1819-20, when Prof. Oersted of Copenhagen put a new interrogation to nature by asking what would take place in regard to a magnetic needle when a wire transmitting a current of galvanism was brought near it. He found that when the wire was brought parallel to and near the needle, the latter tended to turn at right angles to the former. This was a new result, unlike any phenomenon before discovered. Previous to this, the connection between electricity and magnetism had been sought in the analogy of the polarity of the two ends of a magnetic bar and the two extremities of a galvanic battery, both of which exhibited polarity. An account of this remarkable discovery was published in all parts of the civilized world, and everywhere excited the interest of men of science. It was repeated in England, France, and Germany. The additional fact was discovered by Arago in France and Davy in England, that the wire joining the two poles of a galvanic battery while the latter was in action was capable of imparting magnetism to iron filings; but the person who seized on the phenomenon with the greatest avidity, and who in the course of a few months developed the whole subject to such an extent as to elevate it to the rank of a new science, was Ampère, of the French academy. He discovered an additional fact which gave a key to all that had previously been found by his contemporaries, namely, that two parallel wires transmitting currents of electricity in the same direction attract each other, while similar wires transmitting currents moving in opposite directions repel each other. On this fact, combined with the hypothesis that all magnetic action consists in the attraction or repulsion of electrical currents, he founded his celebrated theory of electro-magnetism, which gives in a single sentence a generalization from which all the known phenomena of electro-magnetism as well as ordinary magnetism can be deduced. This theory is based upon one fact and one hypothesis. The fact is this, that currents moving in the same direction attract, and moving in opposite directions repel, each other; the hypothesis is, that the magnetism of a bar of steel consists in currents of electricity revolving at right angles to the length of the bar around each particle of the metal, the resultant of which would be a current around the circumference of the bar. Let us suppose a number of shillings or cents piled one on the other, and cemented together so as to form a cylindrical column or rod 8 or 10 in. in height; and let us further suppose that on account of some molecular action a current of electricity is perpetually circulating in the circumference of each piece of coin, and that the direction of

the currents is the same in the whole series. If we further suppose that the column is standing on end, and that this motion is contrary to that of the sun and contrary to that of the hands of a watch when placed face upward, such arrangement will represent the hypothetical magnet of Ampère, in which the north end, or that which turns to the north, is uppermost, and consequently the south pole undermost. If these postulates be granted, instead of loading the memory with an almost infinite variety of disconnected facts, we shall have at once a generalization from which all the phenomena can be deduced at pleasure in a series of logical corollaries. If this theory be true, or if it be even an approximation to the truth, it will follow that if currents of electricity be transmitted through an arrangement of the kind we have described, the phenomena of ordinary magnetism will be exhibited; and this anticipation will be realized if we coil a piece of copper wire covered with silk into the form of a corkscrew spiral, forming a cylinder 8 or 10 in. long, and if the two projecting ends not included in the spiral be passed backward through the cylinder and made to project from the middle at right angles to the length of the cylinder on opposite sides. If this cylinder, the several spires of which will represent the pieces of money, be supported horizontally, so as to turn freely as a magnetic needle moves on its pivot, it will take a north and south position when a powerful current of galvanism is transmitted through the wire. Nay, more, another cylinder formed of like spires through which a current of galvanism is passing will act upon the first precisely as a magnet would act upon another magnet. Indeed, so long as the galvanic current is passing through this helix or spiral, it exhibits all the properties of an ordinary magnet; but they immediately disappear when the current is interrupted. To deduce from his theory the almost infinite number of facts which it involves, Ampère first considered the action of currents on currents. Starting with the hypothesis that the attraction and repulsion were inversely as the square of the distance between the elementary parts or smallest portion of the currents, he deduced mathematically the consequence that the force of a current of considerable length acting on a single element of a current would vary inversely as the simple distance; and this he was enabled to verify by experiment by suspending a bent wire through which a current was passing so as to be free to oscillate under the influence of a single element, which was ingeniously effected by doubling a piece of covered wire in the middle of its length, thus >. When a current was passed through this double wire, the portion of it which went to the point of bending and that which came from it neutralized each other, and the residuary effect therefore was that of a single point, which gave a result exactly in conformity to the deduction from the theory. After proving experimentally this fundamental principle, he was enabled by

mathematical reasoning, principally of a simple character, to deduce the resultant action of the most complex forms of conductors upon conductors. Among many others, the following important deductions immediately flow from the premises assumed. If a current of electricity be sent in the direction from A to

B through a straight conductor, A B, of indefinite length, placed for example horizontally, and a current be sent

downward through a terminated conductor, CD, perpendicular to the former, the latter conductor will be impelled parallel to itself along the length of the horizontal conductor. This effect will be due to the fact that on the right side of the short conductor the elements of the two currents are moving in opposite directions; the current in the short wire is approaching the point F, while the current in the horizontal wire is moving from this same point, and hence on this side repulsion will take place; while on the left-hand side of the short wire the two currents are moving toward the same point, and therefore attraction will be exhibited; and under the influence of these two forces, the short conductor will move parallel to itself from right to left along the horizontal conductor. If the direction of the current in either of the two conductors be reversed, the motion of the short conductor will also be reversed. If, instead of the short conductor, one in the form of a ring be freely suspended over the long conductor, with the plane of the latter across the former, the current passed through this will ascend on one side of the ring and descend on the other. Therefore, the one side will tend to move to the right and the other to the left, and the resultant action will be to bring the plane of the ring parallel to the horizontal current; in which case the current in the lower part of the ring will be moving in the same direction as the current in the long wire. Now, since, according to the theory of Ampère, magnetism depends upon currents of electricity, it follows that the magnetism of the earth results from currents of electricity moving continually from east to west. Hence, if a conductor be bent into the form of a ring or hoop, and freely suspended, it will arrange itself east and west. To insure the success of this experiment, the hoop should be formed of a long wire covered with silk and coiled into the form of a ring so as to multiply the actions. Such a ring may be considered as one of the disks represented by the shillings in the hypothetical magnet; and since each disk making up the whole length of the rod would be similarly acted upon by the currents of the earth, the axis of the rod would assume a north and south direction if left free to move, thus affording an explanation of the fact, so long considered an ultimate one, of the directive property of the needle. Let us return again to the action of the long horizon-

tal conductor on the short perpendicular one. If the former be bent into a horizontal circle, then it is evident, from the reasons we have before given, that the short conductor, moving perpetually round it parallel to itself or retaining its perpendicular position, will describe a

FIG. 1.—Rotation of a Vertical Current.

circle. This may be shown experimentally by bending a piece of wire into the form of a \cap , and supporting it vertically on the point of a perpendicular wire which fits lightly into a socket on the under side of the middle of the arch. (See fig. 1.) If the two ends of this bent wire dip into a circular basin of mercury through the middle of which, surrounded by a glass tube, the supporting pointed wire passes, and if a powerful current of galvanism be sent down through this wire, it will descend through the legs of the \cap into the mercury; and if at the same time a powerful current be passed through a ring or hoop conductor placed horizontally around it, a rapid rotation of the bent wire will take place. Now since magnetism, according to the theory which we have adopted, consists in currents of electricity revolving at right angles to the magnet, if a magnetized bar be introduced within the branches of the bent conductor, a similar rotary motion will be produced. This fact was first shown experimentally by Prof. Faraday. It is, however, a logical consequence of the theory of Ampère, and might have been deduced from it. A beautiful illustration of the phenomena of terrestrial magnetism was first exhibited by Prof. Barlow of Woolwich, England. He prepared a wooden globe, into the surface of which a long conductor was buried in a spiral groove extending with many turns from pole to pole. This globe was afterward covered with paper, on which were drawn the continents and oceans. When a small dipping needle was placed over this apparatus and a current of galvanism sent through the concealed conductor, the needle assumed a direction similar to that which would be due to an analogous position on the earth's surface; and since, in all cases, the needle tends to arrange itself at right angles with the direction of the current, by a proper adjustment of the conducting wire in the groove the variation of the needle at every point of the earth's surface could be accurately represented. The explanation of all the phenomena of ordinary

magnetism readily flows from the same principles. We have stated that if a magnet be broken in two, each half becomes a separate magnet, exhibiting north and south polarity. If the hypothetical magnet which we have illustrated by a pile of shillings be broken in the same way, each part will become a separate magnet, and the two ends of the two parts which were previously in contact will attract each other, because the currents will be revolving in the same direction; but if we turn the other end of one magnet to the same end of the other, repulsion will ensue, because the currents are revolving in different directions. By a little reflection it will not be difficult to explain or to anticipate the action of the two mag-

nets on each other under any assumed condition. In adopting this hypothesis, it is not necessary to contend for the actual existence of electrical currents in the magnet or even in the earth. It is sufficient to assert that all the peculiarities of the known phenomena of magnetism are precisely such as would result from an assemblage of currents such as Ampère has supposed to exist. It is probable that in the phenomena of magnetism a molecular distribution of the fluid takes place which is analogous to that in a wire transmitting a current. Indeed, we know that at the moment of magnetizing a bar of iron, a molecular change is produced in the metal of sufficient intensity to cause a sensible sound; a fact which was first noticed by Prof. Charles G. Page of Washington.—It is an interesting fact in the history of science, that discoveries in one branch serve to throw light on other branches, and in many cases to furnish instruments by which actions too delicate to be appreciated by ordinary means may be exhibited and measured. Soon after the discovery of Oersted, Prof. Schweigger of Germany covered a long wire with silk and coiled it into the form of a rectangle, within which he suspended by means of a fibre of silk a magnetic needle. When a very feeble current of electricity was sent through this conductor, each turn of the wire acted on the needle to turn it at right angles to its own direction; and in this way an instrument called the galvanometer was produced, by which the most feeble galvanic action in the form of a current is exhibited.—It has been before stated that Arago and Davy discovered that the conducting wire through which a galvanic current is flowing is capable of inducing magnetism in iron filings. They also showed that a discharge of ordinary electricity, when made above or below a sewing needle, gave it definite polarity; and in this way the reason of the failure of Franklin and others, who had attempted to magnetize steel wire by ordinary electricity, was explained. In these attempts the electricity was sent through the length of the

needle, instead of across or around it, as the theory of Ampère would indicate. Mr. Sturgeon, in England, was the first to construct an electro-magnet, which consisted of a piece of iron wire bent in the form of a horseshoe, insulated with a coating of sealing wax, over which was loosely coiled a few feet of copper wire. (See fig. 2.) When the current was sent

FIG. 2.—Horseshoe Electro-magnet.

through the latter, the iron became magnetic, and exhibited in proportion to its size a very intense action. The first person, however, who exhibited the great power of the galvanic current in producing magnetic effects was Prof. Henry of Washington. He found that by surrounding a large bar of iron bent into the form of a horseshoe with a number of coils of wire, so connected with the battery of a single element that the current in each wire would move in the same direction, a magnetic power of astonishing magnitude could be produced with a comparatively small galvanic apparatus. A magnet constructed on this principle, now in the cabinet of the college of New Jersey, at Princeton, will readily support 3,500 lbs. In order, however, to produce a maximum effect of this kind, it is necessary that great care be taken in the insulation of the wires, that there be no cutting across from one wire to another; and for this purpose the ends of two wires intended to be soldered to the positive pole of the battery should project together, while the two ends intended to be united to the negative pole of the battery should also be associated. If the magnetic power of the iron is to be developed by means of a compound battery, then a single long wire may be employed instead of a number of short ones. The power of the electro-magnet depends on the following conditions: on the energy of the current, the dimensions and form of the iron, the nature of the iron—the softer the better—the perfect insulation of the wire, and the proper adjustment of the length of the wire to the intensity of the battery. By means of an electro-magnet of the kind we have mentioned, the instantaneous development of an immense magnetic power is produced, by which discoveries have been made in regard to this mysterious agent, of the highest interest. Prof. Faraday showed by the application of this instrument that magnetic property is possessed by all bodies, either in the direction of the greatest length of the body, the form in which it is ordinarily developed, or at right angles to this length. He found, for example, that when different substances are made into bars and suspended by means

of a fibre of silk between the poles of a powerful electro-magnet, they arrange themselves with the longer axis in the direction of the pole or with the shorter axis in the same direction. Bodies of the former class are called magnetic; those of the latter class are called diamagnetic. This property is even possessed by gases. (See DIAMAGNETISM.) An electro-magnet even of immense power can be magnetized, unmagnetized, and remagnetized in an opposite direction, by instantaneous changes in the direction of the current of the galvanic battery. The large magnet we have mentioned as at Princeton can be loaded with several hundred pounds, and while in this condition may be so rapidly unmagnetized and remagnetized with the opposite polarity that the weight has not time to commence its fall before it is arrested by the attraction of the reverse magnetism. This sudden change of polarity affords a means of producing mechanical movements of considerable power through the agency of electro-magnetism, which have by some been considered as a rival to steam power. The first machine moved by this power was invented by Prof. Henry immediately after his experiments in developing electro-magnetism, and an account of it was published in the "American Journal of Science" in 1831. It consisted of an oscillating iron beam surrounded by a conductor of insulated copper wire. A current of electricity was sent through this in one direction, which caused one end to be repelled upward and the other attracted downward by two stationary magnets. The downward motion of the one end of the beam near its lowest point brought the conducting wires in contact with the opposite poles of the battery, which produced the reverse motion, and so on continually. In a subsequent arrangement, the velocity of motion was regulated by a fly-wheel, and electro-magnets substituted for the permanent magnets at first used. Prof. Ritchie of the London university afterward produced a rapid rotatory motion between the two legs of an inverted horseshoe magnet in a piece of iron around which a current of electricity was made to revolve, and the magnetism reversed at each semi-revolution. Modifications of these two forms of the apparatus have since been made in almost every part of the civilized world. A large electro-magnetic engine was constructed by Prof. Jacobi of St. Petersburg, by which a small boat was propelled at the rate of several miles an hour. But the largest and most efficient engine of this kind was constructed by Prof. Page of Washington, at the expense of the government. It exhibited sufficient power to propel with considerable velocity a railway car, and afforded the best means which has yet been presented of estimating the comparative cost of the application of electricity as a motive power. From all the experiments which have been made, it appears that though the electro-magnetic power can be applied with less loss in the way of effective work than heat by means of the steam engine,

yet the cost of the material by which it is generated is so great that it cannot be economically employed. According to the experiments of Despretz, one pound of coal in burning develops as much heat as six pounds of zinc; consequently, under the same conditions, six times as much power is developed from the burning of an equal weight of the former as from that of the latter. Now the power of the steam engine is produced by the burning of coal in air, while that of the electro-magnetic engine is developed from the oxidation or burning of zinc in acid; and since coal and air are the simple products of nature, while zinc and acid require artificial preparation at the expense of power, it must be evident that electro-magnetism cannot compete with steam, although it may be applied in some cases where the expense of materials is of secondary consideration. Electro-magnetism, for example, is applied with much success in calling into operation power at a distance, as in the case of the electro-magnetic telegraph, in giving simultaneous motion to the hands of clocks situated in different parts of a city, in measuring very minute portions of time, and in bringing into action the power necessary to ring alarm bells.—For an exposition of the scientific principles of electro-magnetism, see De Montferrand's work on the subject, translated from the French by Prof. Cumming of Cambridge, England; and for various ingenious modifications of apparatus, and interesting facts of the science, Dr. Page's papers in the "American Journal of Science and Art." (See GALVANISM, MAGNETISM, and MAGNETO-ELECTRICITY.)

ELECTRO-METALLURGY, Electrotyping. See GALVANISM.

ELEMENT, Chemical. In the present state of science this term admits of no very precise definition. In general the word element is applied to any substance which has as yet never been decomposed into constituents or transmuted into any other substance, and which differs in some essential property from every other known body. Several elements indeed occur under two or more allotropic conditions, in which states they exhibit different properties. These modifications are however mutually convertible into each other, and are regarded as mere varieties of one and the same substance. As now used, the term element does not possess in any degree the absolute signification at one time attached to it, none of the elements now admitted being regarded as proved to be primary principles of matter, although it is not impossible that some of them may be such. Provisionally, all substances which have hitherto resisted every method of analysis that has been applied to them—all, in short, which cannot be proved to be compound—are called elements. The number is increasing, some having been discovered by means of the spectrum analysis: cesium and rubidium by Bunsen and Kirchhoff in 1860, thallium by Crookes in 1861, and indium by Reich and Richter in

1863. There are now 64 admitted in the list. Whether the number will continue to increase, or whether it may be diminished by the discovery that some of them are different conditions of the same substance, of course cannot be foretold. Some of these so-called elements are exceedingly rare, and have been seen but by few persons besides their discoverers. Two have been proposed which are not included in the list, dianium and norium, their existence being uncertain, and their properties not well known. The great mass of the matter of which the world is composed consists of about 30 elements, the remaining 34 being comparatively rare.—For a complete catalogue of the elements, see EQUIVALENT.

ELEMI, a resinous exudation from a number of trees in different parts of the world. Coming from so many sources, the substance known in common is by no means of uniform character, and the trees which afford the gum are very little understood. That from Holland is supposed to be from the Dutch East India possessions, and the product of the *canarium balsamiferum* of Ceylon. The Manila article is believed to be the product of the *canarium commune*; that of *C. album* or *arbolabrea* is used in the Philippine islands for pitching boats and vessels. The Brazilian elemi is from the *icica icicariba*; the *icica* is a genus separated from *amyris*, to which the elemi is commonly referred. The Mexican is said by Dr. Royle to be from a species of the *elaphrium*, which he names *elemiferum*. The resin is imported in various shapes, and in different colors and degrees of consistency. It was formerly much employed in plasters and ointments, but is more used in Europe than in this country. Hatters make use of it, and it is in some demand for varnishes by coach painters. It is one of the ingredients of pastilles burned as incense. It has been resolved into two resins, one amorphous and one crystallizable; for the latter the name elemine has been proposed by its discoverer, M. Baup. In its medicinal properties it resembles the oil of turpentine.

ELEONORA OF ESTE, an Italian princess, born June 19, 1537, died Feb. 10, 1581. She resided in Ferrara at the brilliant court of her brother, Alfonso II., of which she and her sister Lucrezia were the most accomplished ornaments. Tasso seems to have conceived an ardent passion for Eleonora, and to have addressed to her some of his most fervent effusions, to the discovery of which the persecutions to which he was subjected by Alfonso were in part ascribed. But the evidence on the subject is conflicting. There were several other ladies of the name of Eleonora whom Tasso celebrated; as, for instance, Eleonora San Vitale, the beautiful countess of Scandiano, in whose praise he wrote charming verses. However, most biographers agree in pointing to the princess Eleonora as the lady of his special adoration. How far the princess reciprocated his affection is not clearly estab-

lished, and the presumption is that she gave him only friendship and poetical sympathy in return for his love. She was never married.

ELEPHANT (*elephas*, Linn.), the only existing representative of the proboscidean pachyderms, the mammoth or fossil elephant and the mastodon having lived in the preceding geological epoch. The elephant, the largest and heaviest of terrestrial animals, has from time immemorial been celebrated for his intelligence and sagacity, for the services he has rendered to man in eastern lands, for his imposing appearance, for his immense strength guided by gentleness and docility, and for the astonishing feats he is able to perform by means of his trunk. Since the time of Cuvier the anatomy of the elephant has been thoroughly studied. The skull is remarkable for its vertical elevation, giving to the head the well known aspect of sagacity; this, though far superior to that of the other pachyderms, has doubtless been overrated from the peculiar cranial formation in this animal. The great elevation of the frontal region does not arise from any increase of the cranial cavity or corresponding development of brain, but depends on the great separation of the tables of the skull, and the excessive enlargement of the frontal sinuses, affording ample space for the origin of the muscles of the trunk; the upper jaw has a similar structure for the accommodation of the enormous tusks; in both cases strength and solidity are obtained without too much weight. The nearly perpendicular facial line of the elephant, then, depends on the size of the frontal sinuses, the shortness of the bones of the nose, and the vertical position of the maxillary and intermaxillary bones; and the cranial cavity occupies but a small part of the head at its posterior central portion. The occipital bone forms the posterior wall of the skull, and advances also on to its upper surface; the parietals are early consolidated to it, to each other, and to the temporals, forming a solid box; the ethmoid is large, and the extent and surface of the cribriform plate indicate a delicate organ of smell; the sphenoid is very flat internally, but its cells are enormously developed, encroaching largely upon the base of the skull. The teeth consist of two long curved tusks, one in each intermaxillary bone, and of large and compound molars in each jaw. The permanent tusks, which are monstrous incisor teeth, are preceded by two small deciduous ones, which make their appearance between the fifth and seventh months, rarely exceed two inches in length and one third of an inch in diameter, and are shed before the second year, their roots being considerably absorbed; about two months after the milk teeth are shed, the permanent tusks, which are situated to the inner side of and behind the former, pierce the gum when about an inch long, and grow from the base during the whole life of the animal. The molar teeth are remarkable for their size and the complexity of their structure;

there is not more than one wholly, or two partially, in use on each side in each jaw at one time; they are constantly in progress of destruction and formation, succeeding each other horizontally, instead of vertically as in other mammals; according to Owen, the molars are successively brought forward until each jaw has had on each side 6, or 24 in all. Each tooth is composed of a number of transverse vertical plates of dentine or ivory, enveloped in enamel, and united together by the cement of *crusta petrosa*; only a small portion of the crown appears above the gum. This gradual progress of the teeth from behind forward explains how the elephant has always a grinding surface ready to bear the great pressure to which his teeth are always subjected; the constant wear of the grinding surface keeps it in order for mastication; the manner in which the enamel is arranged on this surface, after the ivory is worn down, enables the anatomist to refer a tooth either to the Asiatic or African elephant. From the oblique position of the molars in the jaws, the anterior portion pierces the gum first, and may be quite worn while the middle and posterior portions are slightly or not at all used, so that these teeth diminish in length at the same time that their depth is worn away; as the anterior grinding surface becomes useless, the root is removed by absorption, enabling the tooth to be pushed forward by that behind. The tusks are formed of ivory and enamel, the former making the central and by far the largest portion; the tusks exist in both sexes, but are smaller in the females than in the males; they sometimes measure 9 ft. in length, and weigh over 200 lbs. the pair; this great weight is kept in place only by the tight embrace of the socket and surrounding parts, explaining the abnormal direction of the tusks produced either by sudden and violent or by gentle and long continued pressure. The lower jaw is massive, and prolonged in front, where the extensible lower lip is elongated into a triangular deeply concave organ for receiving the extremity of the trunk. The spine consists of 7 cervical vertebrae, 20 dorsal, 3 lumbar, 5 sacral, and from 24 to 26 caudals; the number of ribs is 19, and in some specimens 20, of which 5 or 6 are true. The thoracic cavity is very large, the ribs being continued back nearly to the pelvis, of great size and width; the sternum is long, compressed laterally, and somewhat prolonged in front. The limbs being designed more for strength and solidity than speed, their bones are thick and large; the shoulder blade is wide, its posterior margin much the shortest; and the spine, beside the acromial process, has a broad, sickle-shaped prominence extending downward and backward; there is no clavicle, as the approximation of the limbs toward the centre of gravity is necessary to support the weight of the body. The humerus is short and massive, the upper extremity having a flat articular surface with large protuber-

ances for the insertion of the muscles of the shoulders, a strongly ridged shaft, and a pulley-like lower surface for the forearm, admitting only of flexion and extension; the external condyle is very extensive upward. The radius and ulna are permanently pronated, and both enter into the formation of the elbow and wrist joints; the eight bones of the wrist are arranged in two rows, and the five metacarpals are short and robust, five fingers being attached to them, but concealed by the thick and overhanging skin, with the exception of the ends. The pelvic bones are large, to accommodate the powerful muscles to which they give origin; the ilia are broad, rounded anteriorly and concave toward the abdomen; the femur is simple in shape, comparatively smooth, resembling considerably that of man; this resemblance is continued in the leg and tarsus; the os calcis is very large and prominent; the metatarsus consists of five bones, the external one being imperfectly developed; the toes are also five, each consisting of three bones, except the outer, which has one, all encased in the thick skin, the division being indicated only by the projecting extremities. The bones of the elephant may be easily distinguished from those of other quadrupeds; they resemble, except in size, the bones of man, particularly the cervical and dorsal vertebræ, the shoulder blade and pelvis, the femur, tarsus, and the bones of the metacarpus and metatarsus; so that it is not surprising that even anatomists, ignorant of the elephant's skeleton, should have mistaken their recent and fossil bones for the remains of gigantic human beings. The food of the elephant is entirely vegetable, and must be immense in quantity, and the digestive apparatus is accordingly largely developed. The stomach is simple, of a lengthened and narrow form, its cardiac extremity being prolonged into a pouch of considerable size, its internal membrane divided into thick folds and transverse wrinkles, and its muscular coat very thick; the small intestines are voluminous, and the large of enormous size; in a moderate-sized animal the intestinal canal was 60 ft. long, the small intestines being 38 ft., the cæcum $1\frac{1}{2}$ ft., and the large $20\frac{1}{2}$ ft.; the circumference of the first being 2 ft., of the second 5 ft., and of the last (colon) 6 ft. The gall bladder is situated between the coats of the duodenum, and is divided by transverse partitions into four compartments; the spleen is 4 ft. long. The heart resembles that of the rodents in having three venæ caviæ opening into the right auricle, two above and one below, and the Eustachian valve is furnished with a rudimentary superior division. The brain is small in proportion to the size of the animal; in one $7\frac{1}{2}$ ft. high the whole organ weighed but 9 lbs., and in another 9 ft. high the internal capacity of the cranium was only 354 in., being less than three times the weight of the human brain, and less than four times the capacity of the Caucasian skull; the convolutions are well marked, and the cerebellum is proportionately very large;

the fifth pair of nerves, which supply the trunk, are enormously developed. The trunk of the elephant is an elongated nose, but is chiefly an organ of touch, though capable of being used for smelling; it forms a conical mass, 4 or 5 ft. long, gradually tapering to the end, which is provided with a thumb-like appendage, endowed with a most delicate sense of touch, and capable of picking up a needle; it contains a double tube, strengthened by membranes, extending up as far as the bony nostrils, just before which they form a sudden curve; the true nasal passages are provided with a valve by which the cavity of the trunk may be cut off from the nose, a provision rendered necessary when the animal takes fluid into the former. The great bulk of this organ is made up of transverse and longitudinal muscles so arranged that the trunk may be elongated, shortened, raised, and bent in any desired direction, with the precision of the human hand. Though the trunk is capable of performing the most delicate operations, it is also an organ of great strength and a weapon of the most formidable character; with it the animal tears the branches from trees in its search for food, performs the heaviest tasks for his human owner, and defends himself from his smaller enemies; with it he introduces food and drink into his mouth, which, from the shortness of his neck, he cannot bring to the ground; by inspiring through the trunk he fills it with water, which he discharges into his mouth or in refreshing showers over his back. So important is this organ that the animal's first act when in danger is to raise it above his head; when hunting the tiger or other wild animal, he carries it high in the air; any wound of it seems to render him helpless; in ordinary cases he rarely uses it to strike an object. When crossing deep rivers the body is deeply immersed, and respiration can be carried on with only the tip of the trunk above water. The sense of smell is acute, though not resident in the trunk proper, as is indicated by the extent of the frontal and maxillary sinuses communicating with the nose; the sphenoidal sinuses are also of unusual dimensions. The sense of hearing is also acute, as it should be for an animal living in thick woods and jungles, in which vision can hardly detect the approach of an enemy; the ear communicates with extensive bony cells, and the external auricle is large to collect the sounds and convey them to the tympanum. The eye is small, but is well protected by thick lids and a nictitating membrane. The muscular system is of immense strength; and the ligamentum nuchæ, which supports the heavy head, is of uncommon size and firmness.—Elephants inhabit the tropical forests of Asia and Africa, living in troops; though often destructive to trees, and especially to saccharine plants, they are quiet and inoffensive unless attacked; they prefer well watered regions, where a large herd may frequently be seen guided by some old male, keeping in the shade during midday and

feeding at morning and evening; easily alarmed, they retire to the woods at the approach of man, but if pursued will turn and attack him with the greatest fury. Only two species are described, the Asiatic and the African elephant. The Asiatic elephant (*elephas Indicus*, Cuv.), extensively distributed over S. India and the E. Asiatic islands, has an oblong head, concave forehead, and the crowns of the molars presenting transverse undulating ridges; the ears are small compared with those of the African species. The skin is hard and thick, wrinkled about the legs, neck, and breast; the general color is a brownish gray, mottled sometimes with lighter spots; pure white albinos are very rarely seen; the hairs are few and rigid, most abundant on the head; the feet have five toes, the nails of which are seen beyond the cutaneous envelope. The usual height is from 7 to 10 ft., that of the females a foot or two less; specimens are on record considerably larger than

Asiatic Elephant.

this, some having a length of 15 ft. and a height of over 12 ft. The period of gestation is about 20½ months; the new-born animal is 3 ft. high, with all its senses perfect; sucking is performed by the mouth, the trunk being turned back, and is continued for a period of nearly two years. The young grow rapidly, being 4 ft. high in the second year, and are said to be suckled indiscriminately by any female in the herd; they attain maturity at about the age of 30 years, and live certainly for 150 years, and probably for 200. The weight of a full-grown elephant is from three to five tons. One kept in London for many years, between 10 and 11 ft. high, consumed daily three trusses of hay and about 200 lbs. of carrots and fresh vegetables, drinking from 60 to 80 gallons of water. Though the elephant will breed in captivity, the supply for domestic and warlike purposes must be kept up by hunting the wild animals and reducing them to servitude. The favorite way in India is to capture the wild by the aid of tame animals, especially females; these display

as much treachery, ingenuity, perseverance, and courage as ever did human seducer to compass the destruction of a victim. Following in the track of the male wild animals, the wily females move gradually toward them, grazing with the same complacency and indifference as if they were inhabitants of the forest; while the females are cajoling a male, the hunters cautiously approach and fasten his legs by ropes to trees, the former distracting the attention of the intended captive, and even assisting in binding the cords; the females then leave him, when he has discovered his condition, to vent his useless rage to his own exhaustion; further reduced by hunger and thirst, he will soon allow himself to be led by his treacherous companions to stations appointed for the training of elephants, where, after a few months' discipline, he becomes quite docile and contented. There are various other modes of taking elephants by female decoys, by stratagem, and by driving. Elephants, both Asiatic and African, frequently figure in the history of the wars of the Greeks and Romans. Darius III. had a small number of them in his war against Alexander; Porus of India brought a large number into the field against the same conqueror. Seleucus had hundreds of them in his army at the great battle of Ipsus. Pyrrhus of Epirus, Hannibal, and Antiochus the Great fought with elephants against the Romans, who themselves soon made use of them in their campaigns, and also exhibited them at their public shows, triumphs, and combats of wild animals in the theatres. In the ancient Indian empires elephants formed a necessary appendage to the royal retinue; they were used for show, for warlike purposes, and for carrying burdens. In the East at the present time elephants are employed for transporting baggage, dragging artillery over difficult places, and otherwise in connection with army movements, but without entering into the actual manoeuvres of battle; they exercise their strength and sagacity in lifting, dragging, and pushing with their leather-protected foreheads. When the elephant gets under full headway, his speed is considerable, and his momentum overcomes all ordinary obstacles; though able to carry an immense weight on a level surface, he is liable to totter and fall backward when forced up considerable elevations; a strong animal can travel 50 miles a day with a burden weighing a ton. The anecdotes illustrating the docility, affection, sagacity, irritability, capriciousness, and revengeful spirit of the elephant are innumerable. The natural enemies of the elephant, besides man, are the tiger and the rhinoceros, and the nasal horn of the latter often proves a more formidable weapon than the trunk and tusks of the elephant; the sight of even a dead tiger is enough to excite most elephants into a transport of fury. —The African elephant (*E. africanus*, Cuv.; genus *loxodonta*, F. Cuv.) has a more rounded head, a rather convex forehead, enormously

long ears, and cheek teeth with lozenge-shaped divisions of the crown; the generic name of F. Cuvier was founded on the last characteristic. It inhabits Africa from Caffraria to the Niger, living in similar localities and with the same manners as the other species. The males attain a height of over 12 ft., but decrease in size north of 20° S. latitude; the tusks, however, are larger as you approach the equator; the females are smaller than the males. The natives estimate the height of this species by doubling the circumference of the impression made by the fore foot; this is tolerably accurate for adult animals. In the most favorable localities the African elephant is considerably larger than the Asiatic; but toward the equator the female African is about as large as the Asiatic male. The ear of the African species is sufficient to distinguish it, being often more than 5 ft. long and 4 ft. wide, three times as large as that of the other species; it descends

African Elephant.

upon the legs, and is frequently used as a sledge at the Cape of Good Hope. From the ancient coins it is evident that this species was known by the old naturalists, and it has been justly said that Aristotle knew it better than did Buffon. It seems to be a dainty feeder, selecting the sweetest fruits and vegetable matters containing sugar, mucilage, and gum; there is a dwarfish evergreen, the *speck boom*, which forms very dense jungles in Caffraria, utterly useless on account of its pithy branches even for fuel; this is a favorite food of elephants, which formerly frequented this region in large herds, whose paths are still discernible on the hillsides, and whose bones are still bleaching in all directions. From this selection of food they are not so injurious to the vegetation of a district as would be supposed, quality being more requisite than quantity. Most of the native tribes hunt them more for their flesh than their ivory, the latter, until the advent of Europeans, being of little value to them except for rings and ornaments; the

flesh is much relished as food, and the internal fat is highly prized for domestic and medicinal purposes. They hunted them with light javelins of their own making, overpowering them by numbers. This species is wilder and fiercer than the Asiatic elephant, defending its young with great courage, and furiously attacking the hunter; though not domesticated in modern times, it probably might be as easily as the other species, were the same pains taken to tame and train it; it can hardly be doubted that the elephants used by the Carthaginians in their wars with the Romans were of African origin. The male tusk is from 6 to 8 ft. long, and weighs from 60 to 100 lbs.; Cumming mentions a single one in his possession 10½ ft. long, and weighing 173 lbs.; the price which they bring in the English market is from £22 to £32 per 112 lbs., according to quality. Such is the terror which these animals have acquired from the persecutions of man, that a child will put a herd to flight; they are very difficult to hunt, from their hiding themselves in the most remote and inaccessible forests, going often 20 miles by night to water. When at ease they sleep on their sides, but when liable to be disturbed they sleep standing; their gait, when natural, is bold, free, light, and graceful. Cumming in his "Hunter's Life in South Africa" gives an interesting description of the manner in which the Bechuanas cook the feet and trunk of the elephant in hot earth and sand. In his experience from 5 to 30 rifle shots were necessary to kill an elephant, and the best place to direct them is just behind the shoulder; it is useless to aim at the front of the head, as the chances of a ball penetrating the brain from this direction are very small. Sir Samuel Baker in his "Rifle and Hound in Ceylon," however, says that he was accustomed to kill elephants by a single rifle shot directly in the forehead. —Many species of fossil elephants are described from the drift of Europe and Asia; the best known of these, the *E. primigenius* (Cuv.), will be treated in the article MAMMOTH, which is the common name; their remains have been abundantly found in Siberia, and fossil ivory from this source has been an important object of trade. The fossil elephants of Europe resemble most the Asiatic species, but they were more bulky, with larger tusks, narrower teeth, and with the skin covered with hair and wool to enable them to dwell in climates colder than any in which these animals are now found, though not in a climate so rigorous as that of Siberia at the present time, which would be unable to furnish the necessary vegetable food. Fossil species resembling the African, and others with mastodon-like teeth, have been found in the Himalaya mountains by Cautley and Falconer. The fossil elephant of North America is said by Prof. H. D. Rogers to occur above the drift, in the superficial deposits of a distinctly later age; it must therefore have been contemporary with the *mastodon gigan-*

teus; indeed their bones and teeth have been found side by side in the marshy alluvium of Big Bone Lick, and the two animals must have been exterminated together.

ELEPHANTA, or **Garapori**, a small island of British India, on the E. side of Bombay harbor, about 5 m. from the mainland; lat. $18^{\circ} 57' N.$, lon. $73^{\circ} E.$; circumference about 5 m. It consists of two hills with a valley between them. It is much overgrown with wood, but diversified with some rice fields and pastures. The inhabitants, about 100 in number, are engaged in rearing sheep and poultry for the Bombay market. The usual landing place is on the S. coast, about 250 yards from which, rudely cut from an isolated black rock, was the figure of an elephant 13 ft. long, now fallen to decay, from which the European name of the island is derived. Further inland, about half way up the N. side of a hill, is a remarkable cave temple of unknown antiquity, which

capello. Several other figures of Siva, one of the four-faced Brahma, and one of the double deity, half male, half female, called Viraj, formed by the union of Siva with Parvati, are also to be seen. There are two smaller excavations on the E. and W. slopes of the hill, similar to the great temple, and filled with representations of Hindoo deities. But what is most remarkable is, that although most of the subjects of these sculptures are evidently Brahmanical, and the temples were probably dedicated to Siva, there is at least one figure which appears to be that of Buddha. No record of the origin of the shrines can be found. The general opinion of Europeans who have examined them is that they date after the birth of Christ, perhaps as late as the 9th or 10th century.

ELEPHANTIASIS. Under this common name two entirely different diseases are comprehended: *E. Arabum*, elephant leg, or Barbadoes leg; and *E. Gracorum*, elephant skin, or tubercular elephantiasis. 1. *Elephantiasis Arabum* was described by Rhazes in the 9th century; it prevails extensively in Barbadoes, and is common in Demerara, Cayenne, and Brazil, in the S. W. part of the island of Ceylon, and on the Malabar coast in India; it is sometimes found in Castile and the Asturias in Spain, and occasional sporadic cases are met with throughout Europe and America. Notwithstanding its name, the disease is not con-

Triad Figure, interior of Temple at Elephanta.

has long been deserted by its priests, and is now frequented only by married women praying for fecundity. The spacious entrance, 60 ft. wide and 18 ft. high, is supported by two massive pillars and two pilasters, being thus divided into three passageways. The interior breadth of the cavern is 123 ft., and its length, presenting a seemingly endless vista of huge columns cut from the living rock, some of them broken by the Portuguese, who formerly possessed the island, is about 130 ft. The roof is generally flat, though not a perfect plane. The sides are excavated into compartments, all filled with mythological sculptures. Opposite to the main entrance there is a bust supposed to represent the Hindoo trinity, Brahma, Vishnu, and Siva. The heads are 6 ft. long and well cut. The head dresses are curiously ornamented, and among other symbols a human skull and a young infant are represented on that of Siva, who also holds in his hand a cobra de

finned to the leg, but may attack almost any part of the body. The attack is ushered in by marked rigor, headache, pain in the back and limbs, followed by heat of the skin, alternating with profuse perspiration, and attended with burning thirst; at the same time some part of the body becomes red and swollen, hot and painful, particularly along the tract of the lymphatic vessels. In a few days the symptoms, both general and local, subside, with the exception that the affected part remains more or less swollen. At irregular intervals similar paroxysms recur, the affected part being each time left more swollen and indurated; as the enlargement increases, the skin often becomes rough, covered with scales, and fissured. The disease is usually confined to one part of the body, though occasionally both legs are affected. The affected parts often attain an enormous size. The causes of Barbadoes leg are not understood; its occurrence in particu-

lar districts shows that local causes have something to do with its production. In the West Indies the negroes, and in Ceylon the native race, are affected much more frequently than the whites; and of the whites, the creoles, those born in the country, are more liable than recent immigrants. In the treatment of the disease in the earlier stages, emollient applications, the warm bath, and bloodletting have been advised. Some physicians think benefit has been derived from the exhibition of mercury. When the disease has already made considerable progress, rest in a position which favors the return of the blood from the limb, and compression by means of proper bandaging, are the means most to be relied upon. II. *Elephantiasis Græcorum*, tubercular elephantiasis, appears to have been the disease which during the middle ages was known as leprosy; it is most frequently met with in the West India islands, and in other tropical regions, while it also prevails extensively in certain parts of Norway, where it is known as *spédalsked*. The disease ordinarily commences by the appearance of dusky shining spots upon the skin, slightly swollen, and more or less insensible. After a variable period, which may extend to months, and even years, these spots are succeeded by tubercles or small tumors, soft, reddish, or livid in color, and varying in size from a pea to an English walnut. These tubercles developed upon the face deform it excessively, giving it often a fancied resemblance to the head of the lion, whence one of the names by which the disease is known (*leontiasis*) is derived. As the disease advances, the tubercles become inflamed and ulcerated; the ulcers exude a sanious fluid, and this concretes into thick crusts; the bones become softened and altered in form. In the progress of the disease the gastro-intestinal mucous membrane becomes involved, and tubercles make their appearance in the pharynx; the sense of smell is lost, sight is weakened, and the touch blunted. In this wretched condition the patient may continue to exist a long time, unless cut off, as is commonly the case, by some intercurrent disease. In a second form of the disease, *E. anæsthetica*, patches of an irregular shape, sometimes slightly elevated above the surface, appear upon the extremities, of a tawny color; in whites they are lighter than the rest of the surface; in the negro they are dry, shining, rough, denuded of hair, and insensible. The hands and feet, and afterward the limbs, generally become swollen, stiff, and numb; ulcers form on the metacarpal and metatarsal articulations; these enlarge, penetrate the joint, and finally amputate the toes and fingers. As the disease advances, the pulse becomes slow and the bowels constipated; sometimes it is complicated with the tubercles of the other variety; in other cases the lobes of the ears, the wings of the nose, and the lips become thick, hard, swollen, and ulcerated. The patient is listless, and his in-

tellect enfeebled, and in this condition he may live many years. The causes of tubercular elephantiasis are unknown; it appears to be hereditary; but the once prevalent opinion of its contagiousness is not found to agree with recent observations. Of its proper treatment little is known.

ELEPHANTINÉ, or *Elephantina* (Arab. *Jeziret el-Sag*, "islet of flowers," or *Jeziret el-Aswan*), an island of the upper Nile, about 1 m. long and $\frac{1}{2}$ m. broad, at the foot of the little cataracts, opposite Asswan, the ancient Syene. It is formed of granite covered with a fertile soil. It contains several ancient ruins; among others, the Nilometer mentioned by Strabo, whose upper part was destroyed in 1822, several dilapidated temples, and a gateway, as well as numerous fragments of pottery with Greek inscriptions. In antiquity Elephantiné or Elephantis was renowned for its fertility. Herodotus regards it as marking the boundary between Egypt and Ethiopia. Elephantiné was strongly garrisoned by the Persians as well as Romans. The present inhabitants are Nubians.

ELEUSIS (now *Lervina* or *Lepsina*), an ancient fortified town in Attica, on the bay of Salamis. It was said to have been founded by Eleusis, a son of Hermes. At an early period it was conquered by the Athenians and became one of the most populous cities of Attica. Its principal importance was derived from its being the seat of the celebrated Eleusinian mysteries. These mysteries formed a peculiar religious festival celebrated in honor of the goddess Demeter (Ceres), the patroness of agriculture, and the representative of the procreative power of nature. Originally these celebrations appear to have been something like modern thanksgiving festivals, but afterward a symbolic meaning was attached to them, and they became the vehicle of a secret science, conducive as was believed to eternal bliss. They consisted in dramatic representations of the myth of Ceres and the rape of Proserpine, her daughter, by Pluto, and would seem to have been intended to propagate the belief in the immortality of the soul, and to give an ideal meaning to the coarse fancies of the popular religion. The lesser Eleusinian mysteries were celebrated at Agræ on the Ilissus during the spring, and were a preparation for the greater. The great mysteries were celebrated at Athens and Eleusis in the latter half of September and the first of October; they lasted nine days. Except to murderers, barbarians, slaves, and afterward Epicureans and Christians, the admission to the public performances and religious exercises was free for all; but in the secret allegorical representations none but the initiated were allowed to participate, and they were bound by solemn oaths never to reveal what they had seen or heard. The unity of God and the immortality of the soul are supposed to have been the secret doctrine of the mysteries; and the symbolism of the ceremonies was probably, as Bishop Thirlwall

suggests, the remains of a worship which preceded the rise of the Hellenic mythology. In 1858 a Greek schoolmaster named Vlastos discovered at the village of Hagi-Constantios an inscription upon an old marble slab, containing rules and regulations for the celebration of the Eleusinian mysteries, but nothing was learned from them about their allegorical meaning.—See Uvaroff, *Essai sur les mystères d'Éléusis* (3d ed., Paris, 1816), and Preller, *Demeter und Persephone* (Hamburg, 1837).

ELEUTHERIA (Gr. *ἐλευθερία*, freedom), among the ancient Greeks, a festival commemorative of deliverance from the armies of Xerxes. It was instituted after the battle of Platæa (479 B. C.), and celebrated annually at that place in the month Maimacterion, nearly corresponding to our September. At the dawn of day a procession marched through the town, at the head of which trumpeters blew the signal for battle. At midday a chariot was driven toward the altar crowned with garlands, and leading a black bull. In front of the altar the archon of Platæa immolated the bull to Jupiter and Mercury, eulogized the heroes who fell at Platæa, and sprinkled the ground with wine. Every fifth year there were also contests, chaplets being the reward of the victors.

ELEVATED RAILROAD. See p. 819.

ELGIN, a S. W. county of Ontario, Canada, on the N. shore of Lake Erie, traversed by Otter creek, and bordered by the Thames river; area, about 730 sq. m.; pop. in 1871, 33,666. Capital, St. Thomas.

ELGIN, a city of Kane co., Illinois, on both banks of Fox river, which is spanned by an iron bridge, and on the Chicago and Northwestern railroad, 85 m. W. N. W. of Chicago; pop. in 1870, 5,441. It is laid out with broad streets, contains many brick blocks, and is well provided with shade trees. There is good water power and an active trade with the surrounding country. It is chiefly noted as the seat of the national watch factory, established in 1866, which has a capital of \$1,500,000, employs 550 hands, half of them females, and manufactures 50,000 watches a year, valued at \$850,000. There are also a woollen mill, a flouring mill, a butt and screw factory, a milk-condensing establishment, and two national banks. The city contains 16 public schools, including a high and two grammar schools, with an average attendance of 928 in 1872; two newspapers, a monthly periodical, and several churches.

ELGIN, a royal, parliamentary, and municipal burgh and market town, capital of Elginshire, Scotland, on the S. bank of the Lossie, 115 m. N. of Edinburgh; pop. of parliamentary burgh in 1871, 7,339. It is surpassed by few cities of Scotland in the number and interest of its ancient monuments. In former times it was a bishop's see; its cathedral was founded in 1224, and was burned in June, 1390, by Alexander Stuart, commonly called the wolf of Badenoch. Bishop Barr soon after erected in

its stead a cruciform church with three towers. About 1568 the privy council ordered the lead to be stripped from the roof and sold to maintain the soldiers of the regent Murray. The noble structure has ever since been falling piecemeal to destruction. The great central

Elgin Cathedral.

tower and spire, 198 ft. high, fell in 1711. The chapter house, a beautiful octagon building, with a groined roof, supported by a handsome column in the centre, and elaborately ornamented, is still entire. As late as the beginning of this century Elgin bore an antiquated look, but new houses and streets have taken the place of the old; assembly rooms have been fitted up; a neat modern church has been built; and the streets are well swept, drained, and lighted with gas. Gray's hospital or infirmary, an institution endowed with £26,000, occupies an elevated site in the western part of the city. An orphan asylum here was endowed with £70,000. Elgin has a considerable trade in corn and wool, and markets are held on each Tuesday and Friday. It has also a woollen manufactory, tannery, millstone quarry, and lime works. Three weekly newspapers are published.

ELGIN. **I. Thomas Bruce**, 7th earl of Elgin and 11th of Kincardine, a British diplomatist, born July 20, 1766, died in Paris, Nov. 14, 1841. He passed some time at Harrow and at the university of St. Andrews, studied law in Paris, and having pursued military studies in Germany, entered the army and rose to the rank of general. His time, however, was mostly

passed in diplomatic employments. After filling missions to Brussels and Berlin, he was sent in 1799 as envoy extraordinary to Constantinople, when the idea occurred to him of rescuing from time and the Turks and removing to England the celebrated sculptures which are now in the British museum, and bear his name. He procured the permission of the Porte to take away from the ruins of ancient Athens "any stones that might appear interesting to him." With the aid of a corps of artists, from Italy, and at his own expense (the British government having declined to further the undertaking), he succeeded in the course of ten years in detaching from the Parthenon, or in excavating from the rubbish at its base, abundant specimens of the various descriptions of sculptures with which it was ornamented. The first instalment of these treasures of antiquity arrived in England in 1808, and excited a feeling of admiration and delight, not unmingled, however, with indignation at what was considered the vandalism of Lord Elgin in removing them from their original resting place, or with doubts as to their artistic value. It was said that he had spent much time and money in procuring indifferent Roman marbles of the time of Hadrian, and the project of purchasing them for the nation was strongly opposed. Lord Byron is said to have carried his feelings on the subject of the alleged depredations of Lord Elgin to such an extent, that on a visit to the Parthenon he inscribed in a conspicuous place, *Quod non fecerunt Gothi, hoc fecerunt Scoti*; and he further gave vent to his indignation in the "Curse of Minerva," written in 1811. Among those who urged upon government the purchase of the marbles was the painter Haydon, whose style received its direction from the contemplation of them, and to whose earnest pleas with men in power was partly attributed the offer of £30,000 for the entire collection, made by Mr. Perceval, the premier, in 1811, which however was refused. In 1812, 80 additional cases arrived in England, a number of valuable marbles having previously suffered shipwreck, and in 1815 Lord Elgin offered to make over the collection to the nation for a reasonable sum. In the succeeding year the purchase was effected for £35,000, the actual outlay having exceeded £50,000. The services of Lord Elgin in bringing within the reach of artists, as well as in preserving from the ravages of time, these masterpieces of antiquity, are now fully appreciated; subsequent events having shown that, had he not removed them, the greater part would have been long since destroyed. In the war of Greek independence, and especially in the last siege of Athens in 1826-'27, the Parthenon suffered very serious damage. Lord Elgin was a Scotch representative peer for 50 years. In 1810 he published in defence of his conduct a 4to volume, entitled "Memorandum on the subject of the Earl of Elgin's Pursuits in Greece." **II. James Bruce**, 8th earl of Elgin

and 12th of Kincardine, a British statesman, son of the preceding, born July 20, 1811, died at Dhurmsala, India, Nov. 20, 1863. His studies were begun at Eton, and completed at Christchurch, Oxford, where he graduated in 1833. He was afterward elected fellow of Merton college. He commenced public life as one of the members of parliament for Southampton in 1841, but before the year was out succeeded to the title and estates of his father. In 1842 he was appointed governor of Jamaica, and in 1846 governor general of Canada. He negotiated in 1854 a treaty of commercial reciprocity with the United States, after which he resigned his office, returned to England, and received the appointment of lord lieutenant of Fifeshire. In the spring of 1857 he was appointed minister plenipotentiary to Peking, immediately proceeded to the East, was present at the taking of Canton, and, in conjunction with the French, succeeded by vigorous measures in reducing the Chinese to terms. After signing a treaty with the Chinese commissioners at Tientsin, June 26, 1858, the conditions of which were highly favorable to the British, he sailed for Japan, entered the harbor of Yedo, which the Americans had opened to foreigners, obtained important commercial privileges for his countrymen, concluded a treaty with the Japanese, Aug. 26, and in May, 1859, returned to England. He was again sent to China in the following year, and on the conquest of Peking by the allied French and British entered that city in triumph. He returned in 1861, and in 1862 was appointed viceroy and governor general of India, but was soon compelled by ill health to resign, and died shortly after. His "Letters and Journals," edited by Theodore Walrond, was published in London in 1872.

ELGIN MARBLES, a collection of ancient sculptures chiefly taken from the Parthenon at Athens, now deposited in the British museum. They derive their name from the earl of Elgin. (See **ELGIN**, **EARL OF**.) The sculptures on the Parthenon consisted of three kinds: the colossal statues on the tympana of the pediments, the metopes, and the frieze around the cella. Of the first, the Elgin collection contains statues or fragments of statues from both pediments, those from the eastern, on which was represented the birth of Minerva, being the best preserved, while those representing the contest of Neptune and Minerva for the possession of Attica are chiefly torsos and fragments, procured by excavation. Of the 92 metopes, it contains 15 from the S. side of the building, representing in high relief the combats of the Centaurs and Lapithæ, and a cast from another now in the Louvre. The slabs from the frieze of the cella, representing in low relief the great Panathenæic procession, are the most numerous and the best preserved of all the specimens in the collection. In addition to these, Lord Elgin procured from the ruins about the Athenian Acropolis the colossal

statue of Bacchus from the choragic monument of Thrasylus, one of the caryatides from the temple of Pandrosus, a portion of the frieze from the Erechtheum, and fragments of the columns of the Parthenon and Erechtheum; numerous inscriptions, including that commemorating the Athenians who fell at Potidæa; and urns, &c., taken from various parts of Athens and its neighborhood. The sculptures executed by Phidias, as has been generally supposed, or under his direction, exhibit the highest development of Greek art. As types of beauty they have never been surpassed, and even in their present fragmentary condition they afford models of form which modern art has not been able to equal. Under their influence a national school of sculpture has been established in England. A paper in "Blackwood's Magazine" for December, 1873, by W. W. Story, controverts the opinion that Phidias was the sculptor of the Parthenon marbles.

ELGINSHIRE (formerly **MORAYSHIRE**), a N. E. county of Scotland, bounded N. by Moray frith; area, 528 sq. m.; pop. in 1871, 43,598. It is divided into two parts by a detached portion of Inverness-shire, the smaller on the south. It has a coast line of about 30 m., on which are a few small harbors. With the exception of some broken masses of rock, the surface in this quarter is nearly level, but inland it rises into hills, interspersed with fertile valleys, and diversified by lakes. The Spey, Lossie, and Findhorn, the first and last of which contain salmon, are the chief rivers. Slate and freestone are the only valuable minerals. The climate is mild and dry; the soil of the lowlands is generally fertile, and the hills furnish pasturage for black-faced sheep, cattle, and horses. The staple production is wheat, but oats, potatoes, and turnips are also grown extensively. Less than a quarter of the land is cultivated, and there are large unenclosed tracts. Corn, whiskey, fish, and timber are the most important exports. The county is traversed by a number of good roads, but has no canals or railways. Chief towns, Elgin, Forres, Fochabers, and Burghead.

ELI, judge of the Hebrews immediately before Sammel. He was of the race of Aaron, and officiated as high priest and judge during 40 years; yet he lacked the power to discipline his own family, and a train of woes befell him and his house during the latter years of his life. His piety was exemplary, but his inefficiency was a source of many calamities. After a disastrous battle with the Philistines (about 1110 B. C.), in which his two sons were slain and the ark of the Lord was captured, Eli, on hearing the last news, fell back from his chair and broke his neck, at the age of 98.

ELIAS. See **ELIJAH**.

ELIAS LEVITA (Heb. *Halleri*, the Levite), a Hebrew scholar, born according to some in Francoenia, according to others in Italy, about 1470, died in Venice in 1549. At the beginning of the 16th century he lectured in Padua

on Hebrew grammar, and wrote a commentary on one of Moses Kimli's grammatical works (Pesaro, 1508; frequently reprinted). When Padua was plundered in 1509 he lost all his property, and afterward visited Venice and Rome. Here he became the teacher in Hebrew of Cardinal Egidio. He was again reduced to poverty by the sack of Rome in 1527, and returned to Venice. In 1540, with Paul Fagius, he established a Hebrew printing office at Isny, Swabia; and in 1547 he again established himself in Venice. He rejected many of the Hebrew traditions, and spoke so favorably of the Christians that he was suspected of infidelity to Judaism. But his high personal character and his profound scholarship were never questioned. Besides numerous lexicographical and grammatical treatises, of which his *Tishbi* (Isny, 1541; Basel, 1557) and *Bahur* (Rome, 1518; Basel, 1825) are the most celebrated respectively, he wrote poems, translated the Psalms into German, and was said to be the author of the Jewish-German novel *Baba*. But his great work was *Masoreth hammasoreth* (Venice, 1538), a critical commentary on the Biblical text and its authors. The best translation is the English, published, with a critical edition of the original, by Dr. Ginsburg (London, 1867).

ÉLIE DE BEAUMONT, Jean Baptiste Armand Louis Léonce, a French geologist, born at Canon, Calvados, Sept. 25, 1798. In 1821 he undertook, by order of the government, a series of metallurgical explorations, and was made on his return in 1824 a mining engineer. In 1829 he became professor at the school of mines, in 1832 at the collège de France, and in 1833 engineer-in-chief. After the death of François Arago he was made perpetual secretary of the academy of sciences. Napoleon III. appointed him senator. He was appointed in 1823, together with Dufrenoy, to aid M. Brochant de Villiers in preparing the materials for the geological map of France; and in this commission they were charged to visit England, where a similar work was in progress, and at the same time to examine the metallurgical operations there practised. The results of their investigations were published by Dufrenoy and Élie de Beaumont in a work entitled *Voyage métallurgique en Angleterre* (1827), illustrated with numerous plates, and afterward enlarged with the aid of Léon Coste and Perdonnet. Élie de Beaumont afterward devoted himself almost exclusively to geological researches, while engaged upon the preparation of the map of France, and published frequent papers in the *Annales des mines* and other scientific journals. In his *Notice sur les systèmes des montagnes* (1852), he endeavored to prove that mountain chains are to be classed according to the direction of their range, all those lying parallel with the same great circle of the earth, wherever they may be found, having been uplifted suddenly during the same geological epoch. He described in the last edition of his work the

features of no less than 95 systems of mountains; and the facts he collected added largely to the geological knowledge of the day. A decree of 1868 appointed him to direct a geological survey of France.

ELIJAH (in the New Testament called **ELIAS**), a Hebrew prophet, whose history is given in the later chapters of the first book of Kings, and in the opening chapters of the second. He suddenly appeared before King Ahab, declaring that as a punishment for the king's iniquities neither dew nor rain should fall for years, until he himself announced the change. He took refuge from the wrath of the monarch in the desert, by the brook Cherith, where he was miraculously fed by ravens; and after the drying up of the brook he proceeded to Zarephath, where he was supported by a poor widow, for whom his presence was a source of blessings during the distresses of the time. After drought and famine had desolated the country during three years, he reappeared before the king, offering to demonstrate the vanity of the worship of Baal. He requested Ahab to assemble on Mt. Carmel the idolatrous priests, 850 in number, who had followed in the train of Queen Jezebel, and there defied them to make fire fall from heaven to consume their sacrifice. The long prayers of the Baalites were without success, but in answer to Elijah's short prayer the fire came down and consumed not only the bullock but the altar. The people instantly massacred the priests, and then Elijah promised an end to the famine, and there was an abundant rain. But Jezebel swearing revenge for the destruction of the priests, Elijah again fled to the wilderness of Mt. Horeb and hid himself in a cavern. Then he was commanded to return and anoint Hazael king over Syria and Jehu over Israel, and appoint Elisha as his own successor. On his way he found Elisha and made him his disciple, and as he appeared again before Ahab, who was guilty of the blood of Naboth, the king humbled himself and repented. Ahaziah, the son of Ahab, who succeeded to the throne, fell ill, and Elijah announced to him through his agents that his sickness would end in death. Ahaziah sent a captain and 50 armed men to seize Elijah; but fire from heaven consumed the band. A second company met with the same fate. At length Elijah appeared personally before the king and repeated his announcement. His mission was now accomplished. He made a visit to the school of the prophets at Bethel, and having in company with Elisha crossed the Jordan, the waters of which he divided by smiting them with his mantle, he was taken up into heaven by a whirlwind, in a chariot of fire drawn by horses of fire. The date of the termination of his career is fixed in the beginning of the 9th century B. C.—In the New Testament Elias is mentioned as appearing with Moses to Christ at his transfiguration on the mount. He has been canonized in both the Greek and Latin churches. Among the Chris-

tians in the East Mar Elias is the patron of elevated places, and many conspicuous summits are called after his name. Two convents in Palestine are dedicated to him, one near Jerusalem, and the other on Mt. Carmel. His day is July 20, under which date the traditional account of him will be found in the *Acta Sanctorum*. The Mohammedan traditions respecting him are given in the introduction to Lane's "Arabian Nights."

ELIOT, Charles William, an American educator, born in Boston, Mass., March 20, 1834. His father was Samuel Atkins Eliot, the author of a "History of Harvard College," a member of congress in 1850-'55, and for 11 years treasurer of Harvard college. At the age of 15 the son entered Harvard college, and graduated in 1853. Immediately afterward he was appointed a tutor in mathematics, and held that position till 1858, when he became assistant professor of chemistry. In 1863 he resigned his professorship and went abroad, in order to perfect himself in chemical research and to study the various methods of scientific and literary education in England and on the continent. Returning home in 1865, he was appointed professor of chemistry and metallurgy in the Massachusetts institute of technology. In the spring of 1869 he was chosen president of Harvard university, as the successor of Dr. Thomas Hill, and was inaugurated on Oct. 19. President Eliot has been a frequent contributor to the "Atlantic Monthly," "Journal of Science," and other periodicals; and he is the joint author of a "Handbook of Chemistry" (Boston, 1868). In 1869 he received the degree of LL. D. from Williams and Princeton colleges, and in 1870 from Yale college.

ELIOT, George. See LEWES, MARIAN EVANS.

ELIOT. I. John, commonly called the "Apostle of the Indians," born at Nasing, England, in 1604, died at Roxbury, Mass., May 20, 1690. He was educated at Cambridge, and in 1631 came to Boston, Mass., where he preached to the church of Mr. Wilson, who was then in England. In 1632 he was settled as teacher of the church in Roxbury. Being impressed with the benighted condition of the Indians, whom he fancied to be the descendants of the lost tribes of Israel, he commenced preaching to them in their own language at Nonantum, now a part of Newton. He had acquired their language through the assistance of an Indian servant in his family who had learned English. The first service was held Oct. 28, 1646. After prayer he stated the leading doctrines of Christianity, and applied them to their condition, inviting his hearers at the close to ask any questions. One asked whether God could understand prayers in the Indian language; another, how could there be an image of God since it was forbidden in the second commandment; another, how the Indians could differ so much from the English in their views of religious truth if they all at first had but one father; another, how came the world so full

of people if they were all once drowned in the flood. The conference lasted three hours, and was followed by others in which similar queries were propounded by the Indians, one of whom, very aged, inquired whether it was too late for such an old man as he to repent and be saved. Eliot was strongly opposed by some of the sachems and conjurers, who threatened him with violence if he did not desist from his labors; but his answer was: "I am about the work of the great God, and he is with me, so that I neither fear you, nor all the sachems in the country. I will go on; do you touch me if you dare." A settlement of "praying Indians" was soon formed at Nohantum, which in 1651 was removed to Natick, where in 1660 an Indian church was organized, and the community flourished for many years. Eliot travelled extensively, planted a number of churches, visited all the Indians in the Massachusetts and Plymouth colonies, and once preached the gospel to the famous King Philip, who rejected it in disdain. He induced large bodies of Indians to give up their savage customs and form themselves into civilized communities, led many persons to engage in the missionary work among them, and lived to see 24 of them become preachers of the gospel to their own tribes. His influence over the Indians was almost unbounded. He protected them in 1675, during Philip's war, when some of the people of Massachusetts had resolved to extirpate them; and though he suffered much abuse for the part he took, nothing could shake his friendship for them. At the age of 80 he offered to give up his salary from the church in Roxbury, and desired to be released from his labors as their teacher; and when, from increasing infirmities, he could no longer visit the Indians, he persuaded a number of families to send their negro servants to him every week, that he might instruct them in the word of God. He gave to the Indians most of his annual salary of £50, which he received from the society for propagating the gospel; and it is related that on one occasion, when the parish treasurer was paying him, he tied the ends of the handkerchief into which he put the money in as many hard knots as possible, to prevent Mr. Eliot from giving it away before he should reach home. Calling at once, however, on a family suffering from sickness and want, he told them God had sent them relief, and began to untie the knots; but becoming impatient, he gave handkerchief and all to the mother, saying: "Here, my dear, take it; I believe the Lord designs it all for you." Richard Baxter said of Mr. Eliot, "There was no man on earth that I honored above him." All New England bewailed his death, and Cotton Mather tells us, "We had a tradition that the country could never perish as long as Eliot was alive."—A list of the published works of Eliot may be found in his life, in Sparks's "American Biography." Among them are accounts of the progress of the gospel among

the Indians; the "Christian Commonwealth," published in England about 1660, which when received in Massachusetts was regarded as so seditious, that the governor and council required Eliot to retract its teachings, because opposed to the monarchy of their native country; an Indian grammar (1664); the psalms translated into Indian metre (1664); and a harmony of the gospels, in English (1678). His great work, however, was the translation of the Bible into the Indian tongue; the New Testament was first published at Cambridge in 1661, and the Old in 1663; and both were issued in subsequent editions. This was the only Bible printed in America until a much later period. Copies of it are very rare, and have been sold at £170 and £210. In a late London catalogue a copy is quoted at £225. A copy was sold in New York in 1868 for \$1,180. The language in which it is written has utterly perished, and only one or two persons in modern times have been able to read it. **H. Jared**, grandson of the preceding, minister of Killingworth, Conn., born Nov. 7, 1685, died April 22, 1763. He was a preacher, a botanist, and a scientific agriculturist, introduced the white mulberry tree into Connecticut, and discovered a process of extracting iron from ferruginous sands. He was also the first physician of his day in the colony, was sometimes sent for to Newport and Boston, and was more extensively consulted than any other physician in New England. He published "Agricultural Essays" (1735, several times reprinted), "Religion supported by Reason and Revelation" (1738), and sermons.

ELIOT, John, an American clergyman, born in Boston, May 31, 1754, died there, Feb. 14, 1813. With Dr. Belknap he coöperated in establishing the Massachusetts historical society, and in 1809 published the "New England Biographical Dictionary." He also published sermons and biographies.

ELIOT, Samuel, an American author, born in Boston, Dec. 22, 1821. He graduated at Harvard college in 1839, and passed two years in a counting room and four years in foreign travel and study. While in Rome in 1845 he conceived the plan of writing a history of liberty, the first portion of which he published in Boston in 1847, under the title "Passages from the History of Liberty." In this work he reviewed the career of Arnold of Brescia, Giovanni di Vicenza, Savonarola, and other early Italian reformers. In 1849 appeared "The Liberty of Rome" (2 vols. 8vo, New York). A revised edition was published in 1853, under the general title, "The History of Liberty," with two additional volumes: part I., "The Ancient Romans;" part II., "The Early Christians." These constitute a portion of an extensive history, the remaining three parts of which the author intends to devote to the papal ages, the monarchical ages, and the American nation. In 1856 he was appointed professor of history and political science in Trinity college, Hart-

ford, and the same year published a "Manual of United States History, 1492-1850" (12mo, Boston). He was president of Trinity college from 1860 to 1866, and is now (1874) professor of political science and constitutional law in that institution.

ELLIOTT, George Augustus, Baron Heathfield, a British general, born at Stobbs, Roxburghshire, Scotland, in 1718, died in Aix-la-Chapelle in July, 1790. He was educated at the university of Leyden, and subsequently studied the art of war in the school of artillery at La Fère. He entered the British army in 1735, distinguished himself at Dettingen and in other actions in Germany and the Netherlands, obtained the rank of lieutenant general, and in 1775 was appointed governor of Gibraltar, which he successfully defended for more than three years against the combined French and Spanish forces. On his return to England he received the thanks of both houses of parliament, and was made a knight of the bath by George III.; and in 1787 he was raised to the peerage as Baron Heathfield of Gibraltar.

ELIS, or **Elea**, in ancient Greece, a division of the Peloponnesus, extending along the Ionian sea from the promontory of Araxus to the river Neda; greatest breadth about 35 m., from the promontory of Chelonatas to the foot of Mt. Erymanthus, where the boundaries of Elis, Arcadia, and Achaia come together; area, about 1,000 sq. m. It contained the western slopes of the Achaian and Arcadian mountains, Erymanthus, Pholoë, and Lycæus; and though its surface was for the most part uneven, it had many valleys and hillsides of great fertility. Its principal rivers were the Alpheus (now Ruphia) and the Peneus (Gastuni). The whole territory included three districts: Elis, in its narrower sense, or Hollow Elis; Pisatis, separated from the first by a branch of the Pholoë mountains; and Triphylia, lying S. of the Alpheus. Of these, Hollow Elis, so called from its being a vale set in a circle of mountains, was the most northern and the most fertile. Here, and nowhere else in Greece, grew the fine flax called *byssus*. At the time of the Doric invasion, Oxyllus led the Heraclidæ south by the more difficult way of Arcadia, lest they should see and be attracted by the richness of this plain. Hollow Elis contained three cities, Elis, its port Cylene, and Pylos. These were unwall'd, and protected only by the sanctity of the country; for by the common law of Greece Elis was a sacred state and inviolable, on account of its possession of the temple of the Olympian Zeus on the banks of the Alpheus. This sacred character of Elis was, however, disregarded during the Peloponnesian war by the Athenians. Afterward King Agis of Sparta pressed across the Larissus to attack Elis, but on the first attempt fled, alarmed by an earthquake; and he failed in a subsequent attack. Pisatis, which was the lower valley of the Alpheus, had eight cities, two of which, Pisa and Salmone, are

celebrated in the legends of Cænomaus, Pelops, and Salmoneus. In this district was Olympia, the seat of the most famous of the Greek games, and the quadrennial scene of the most splendid of Greek assemblages. From the time of the Doric invasion there was hostility between the proper Eleans and the Pisatians, caused by the claim of the former to direct the Olympic games. This jealousy gave rise to several wars. The Eleans, finally victorious in the 52d Olympiad, destroyed the city of Pisa. Triphylia, the smallest and the southern division of Elis, was separated from Messenia by the Neda, and was fertile only in the interior. Here was Mt. Minthe, the highest in Elis, one of the seats of the worship of Hades. The Eleans took part in the Trojan, Peloponnesian, and the other general Grecian wars, and were constantly in strife with some one of their neighbors. They retained the celebration of their renowned Olympic games till A. D. 394, when the festival was abolished by the emperor Theodosius. Two years later the country was laid waste with fire and sword by Alaric. Again in the middle ages Elis became of some importance in the hands of French adventurers, and subsequently of the Venetians. But the memory of its ancient religious character, and traditions of its cultivation and large and active population, give to it its only modern interest. Its two northern divisions now form part of the nomarchy of Achaia and Elis, and Triphylia of that of Messenia.

ELISABETHGRAD, or **Yelisavetgrad**, a fortified town of South Russia, in the government and 130 m. N. of the city of Kherson, on the river Ingul; pop. in 1867, 31,968. It is hexagonal in shape, fortified and well built, is the headquarters of the military colonies E. of the Bug, contains a large hospital and five churches, has considerable trade, and the principal annual fair in the government. It was founded in 1754, and named after the empress Elizabeth.

ELISABETHPOL. **I.** A government of Asiatic Russia, in the division of Transcaucasia, bordering on the governments of Tiflis, Baku, and Erivan, and bounded S. by Persia; area, 17,038 sq. m.; pop. in 1867, 503,282. The western portion is mountainous; the eastern is more level. The principal river is the Kur. **II.** A town, capital of the government, on an affluent of the Kur, 90 m. S. E. of Tiflis; pop. in 1867, 14,971. It has several churches and mosques, and considerable trade in fruit. Its original name was Gansha. Here Paskevitch defeated the Persians, Sept. 25, 1826.

ELISHA, a Hebrew prophet, whose history is given in the books of Kings. He was ploughing with twelve yoke of oxen when Elijah called him to the prophetic office. At the moment when Elijah disappeared from the earth, Elisha received his mantle, and was recognized by the other prophets as their spiritual chief. He divided the waters of the Jordan by extending over them the robe of his master; rendered the bitter fountain of Jericho

sweet by casting salt into it; cursed the children of Bethel, who mocked him, and were devoured by two bears; predicted the victory of Jehoram and Jehoshaphat over the Moabites; restored the fortune of a widow persecuted by her creditors; raised to life the son of a woman of Shunam who had given him hospitality; and cured the leprosy of Naaman. He defeated the projects of Benhadad, king of Syria, against Israel, and caused the host sent to capture himself to be struck with blindness. Samaria being reduced to extreme famine by siege, Elisha predicted incredible abundance, which was suddenly obtained by the panic and flight of the Syrian army, who left their tents filled with gold and provisions. He foretold the death of Benhadad, and the succession of Hazael, his murderer. Upon his deathbed he was visited by King Joash, to whom he promised three victories over the Syrians. His death is commonly fixed about 840 B. C.—Elisha is canonized in the Greek church; his day is June 14. Under that date the traditions concerning him are given in the *Acta Sanctorum*. In the time of Jerome his mausoleum was shown at Samaria. Under Julian his reputed bones were taken from their receptacle and burned.

ELIXIR, a word probably of Arabic origin, applied in old pharmacy to certain extracts obtained by boiling; as elixir of vitriol, a mixture of sulphuric acid with some aromatic tincture. In modern pharmacy the name is retained for various tinctures made up of several ingredients. The alchemists applied it to a number of solutions which they employed in the transmutation of metals, and to the *elixir vite*, a preparation which when discovered was to endow the person taking it with immortality.

ELIZABETH, a city and the capital of Union co., New Jersey, on Newark bay and Staten Island sound, 11 m. W. S. W. of New York; pop. in 1850, 5,583; in 1860, 11,567; in 1870, 20,832, of whom 6,752 were foreigners. It is situated on elevated ground on both sides of the Elizabeth river, a small stream emptying into the sound. It is regularly laid out, with broad streets shaded with trees, and contains several small parks and numerous handsome residences. Many retired merchants and persons doing business in New York reside here, and it has long been noted for its wealth, its good schools, and its refined society. Elizabethport, the portion bordering on the bay and sound, can be reached by vessels of 800 tons. It is the seat of nearly all the manufactories, and annually ships large quantities of coal and iron, brought by rail from the Pennsylvania mines. The railroads passing through the city are the New Jersey, the Central of New Jersey, the Newark and Elizabeth, and the Perth Amboy and Elizabethport. It is nearly connected by horse car with Newark, 5 m. distant, and a line of steamboats plies between New York and Elizabethport. The principal manufactories are 2 of cordage, 1 of

edge tools, 1 of gas machinery, 1 of carriages and spokes, 1 of boots and shoes, 2 of zinc, 1 of combs, 1 of lamplack, 1 of saws, 1 of stoves, 1 of straw hats, 1 of trunks, 2 potteries (vitrified stone drain pipe), 5 breweries, 3 planing and moulding mills, and several large iron foundries. The largest establishment is the factory of the Singer sewing machine company, one of the most extensive in the world, recently erected in Elizabethport. There are 2 national banks, with an aggregate capital of \$600,000, 3 saving banks, 1 life insurance and 3 fire insurance companies. The city is divided into eight wards, and is governed by a mayor and a common council, consisting of two members from each ward. The police force consists of a chief and 40 patrolmen. There is a volunteer fire department, and a fire alarm telegraph is in operation. The water works, owned by a private company, supply the greater portion of the city from the upper part of Elizabeth river. The city is lighted with gas, and has 24 m. of streets paved, in about equal proportions, with wooden and stone pavement, and about 27 m. of sewers. The assessed value of property (about one third of the true value) in 1873 was \$15,563,625; total taxation, \$408,994 32, of which \$268,000 were for city purposes. The debt amounted to \$600,000, besides which there were outstanding \$3,000,000 improvement bonds, for which the treasury is to be reimbursed by assessments on the property improved. The principal public buildings and institutions are the court house and county jail, the city hall, 4 public school houses, 6 hotels, the city almshouse, the orphan asylum, and the old ladies' home. The public schools (2 high, 4 grammar, and 5 primary) are under the charge of a board of 16 commissioners, and have an average attendance of about 2,500 pupils. The amount appropriated for school purposes in 1873 was \$32,000. There are a business college, a collegiate school for young men, and five other private schools. The periodicals are three daily, one semi-weekly (German), three weekly, and one monthly. There are 24 churches, viz.: 3 Baptist, 1 Congregational, 4 Episcopal, 1 German Lutheran, 1 German Moravian, 5 Methodist (1 German), 5 Presbyterian, and 4 Roman Catholic, besides a nunnery.—Elizabeth, formerly called Elizabethtown, was settled in 1665, and was the colonial capital from Feb. 24, 1755, to Sept. 13, 1757. A city charter was granted in 1865.

ELIZABETH, second queen regnant of England, and last sovereign of the Tudor line, daughter of Henry VIII. and Anne Boleyn, born at the palace of Greenwich, Sept. 7, 1533, died March 24, 1603. She was virtually made heiress presumptive to the throne immediately after her birth, by act of parliament, to the exclusion of her sister Mary, daughter of Catharine of Aragon, who was more than 17 years her senior. The king, though bitterly disappointed in the sex of the child, showed attach-

ment to her, and interested himself in her education. He purposed wedding her to the third son of Francis I. of France. In her third year her fortunes were clouded by the occurrence of that tragedy which sent her mother to the scaffold. Elizabeth was in her turn declared illegitimate, and fell into contempt. The birth of her only brother, afterward Edward VI., happened in 1537, and her first public act was to bear the christ at his christening, she being herself carried in the arms of Lord Hertford. She was educated by Lady Bryan, a superior woman, and early showed talent. She became attached to her brother, and was on the best of terms with Henry's last three wives. At 10 years her hand was offered to the earl of Arran, but refused. A marriage between her and Prince Philip of Spain was talked of in 1545. The preceding year she had been restored to her right of succession, but the act declaring her illegitimate was never repealed. She already understood the Latin, French, Italian, Spanish, and Flemish languages. She translated a work from the Italian, and dedicated it to her last stepmother; but her favorite study was history. She shared the instruction received by her brother from some of the most learned men of England. Henry dying in January, 1547 (N. S.), Elizabeth found herself by his will the next person in the order of succession to Mary, and in other respects liberally provided for. Lord Seymour of Sudley, an uncle of the king, endeavored to get her for his wife; but he failed, and married Catharine Parr, Henry's last wife; at whose instance Elizabeth had rejected him. Her studies were continued, and she became the pupil of Roger Ascham, on the death of William Grindal, when she was 16. With him she read in Latin the works of Livy and Cicero, and in Greek those of Sophocles, the select orations of Isocrates, and the New Testament. Elizabeth was residing with her stepmother, and the freedom she allowed Lord Seymour caused much scandal and led to her removal to Hatfield. After his wife's death Seymour renewed his acquaintance with Elizabeth, but his arrest and execution on the charge of treason prevented the success of his designs. Elizabeth on hearing of his death merely said that there had died a man of much wit and very little judgment; words which accurately described him. She was now regarded as being in some sort the rival of Mary, and as the chief person in the Protestant party, as Mary was at the head of the Catholics; but this rivalry was ended by the plot of Dudley, duke of Northumberland, to exclude both from the throne, and to secure it for Lady Jane Grey, whom he had caused to marry one of his sons. Edward VI. was Northumberland's tool, and was not allowed to see Elizabeth in his last days. On his death the duke offered Elizabeth a large sum of money and a valuable grant of lands if she would acquiesce in the new order of things; but she referred him to Mary, during whose

life she had nothing to resign. She joined Mary soon after her success, in 1553, at the head of a body of troops. In a month however they became enemies. Mary's adherence to the Roman Catholic faith offended many of her subjects, who looked to Elizabeth as their future sovereign, the queen having passed middle life and being single. Their relative positions were sufficient to cause enmity between them, and Elizabeth's refusal to attend mass offended the sovereign and her Catholic advisers. After much quarrelling the princess affected to give way, and attended the queen at mass. Her object was to have her right to the succession admitted at the coronation, in which she succeeded. The estrangement between the sisters was however renewed when an act of parliament was passed, declaring valid the marriage between Henry VIII. and Catharine of Aragon, from which Elizabeth's illegitimacy followed, though it was not set forth in words. After considerable disagreement and contention at court, Elizabeth was allowed to retire to the country, where she refused to marry either the duke of Savoy or the prince of Denmark. Growing out of the general discontent in regard to the proposed marriage of Mary with Philip II. of Spain, there was a plot to marry Elizabeth to Courtenay, earl of Devonshire, and to elevate them to the throne. Some persons even resolved to resist the Spanish alliance by arms. Sir Thomas Wyatt undertook to raise Kent, and seemed at first successful, but soon his rebellion was put down, and some of the rebels accused Elizabeth of being in the plot, while there were other circumstances that bore against her. A royal commission was sent to remove her to London, which was done, though she was very ill. She was lodged at Whitehall, Mary refusing to see her. The royal councillors were divided, some being in favor of her execution, while others were more merciful. Finally she was sent to the tower, March 17, 1554, where she was examined. She was forced to hear mass. Wyatt exonerated her on the scaffold from being privy to his intended rebellion, but his language was ambiguous, and there seems little reason to doubt her complicity in the plot. The ambassador of Charles V., anxious for the interests of Philip, Mary's intended husband, warmly urged Elizabeth's execution. Mary would not listen to his entreaties, and soon gave orders for her sister's removal from the tower. She was sent to Woodstock, where she remained in detention for some time, and professed herself a Catholic. Mary was married to Philip II. in July, 1554, and her belief that she was to give an heir to the crown had a good effect on Elizabeth's fortunes; she was now taken to London, had an interview with the queen, and appeared publicly at court. Though treated with much respect, she was not made free until some months later, when she was allowed to reside at Hatfield, but with a sort of keeper in her household. She was visited

by the queen, and went herself to court. The object of many plots, her life continued to be unpleasant, and at one time she thought of flying to France. Overtures of marriage were made to her from various quarters, but she would not listen to them. Philip, who now treated her with marked friendship, on politic grounds, was anxious that she should marry Philibert of Savoy, but all his endeavors were fruitless, and he could not prevail upon his wife to coerce her sister's inclinations. The sisters were on good terms during the last months of Mary's life. The queen, anticipating her husband's request, declared Elizabeth her successor shortly before her death, exacting, however, a profession of adherence to the old religion. Affecting to feel hurt that her Catholicism should be doubted, the princess "prayed God that the earth might open and swallow her alive if she were not a true Roman Catholic." She declared that she prayed to the Virgin, and on the day before she became queen the Spanish ambassador wrote to his master that she had told him that she acknowledged the real presence in the sacrament. Mary died Nov. 17, 1558, and Elizabeth ascended the throne without opposition. Cecil was appointed her principal secretary of state, and Nicholas Bacon lord keeper. The queen continued to conform to the Catholic worship until Christmas morning, when she took the final step that placed her at the head of the Protestant world, by refusing to hear mass in the royal chapel. Other changes were made, but her coronation was according to the forms of Catholicism. She sent friendly messages to Protestant sovereigns, and directed her minister at Rome to assure Paul IV. that no violence should be done to the consciences of Englishmen; but the pontiff made only sharp comments on the message, declared that she was not legitimate, and required her to submit her claim, as against that of Mary Stuart, to his arbitration. She recalled her minister, whom the pope frightened into staying at Rome under the threat of excommunication. A bull was issued against Elizabeth soon after, but she was not expressly named in it. The religious change went on, though Elizabeth was averse to innovations, and would have preferred to proceed so slowly as to have virtually kept things in the state she had found them. Catholic and Protestant services were strangely mixed up in her public worship; but this could not last, and 13 bishops were deprived of their sees by parliament for refusing to take the oath of supremacy. The church of England was restored, and the use of the Bible in English was legalized. Philip of Spain sought her hand, and wrote to her often; but though she was anxious not to offend him, England being in a very depressed state, she would not accept the offer. By the treaty of Cateau-Cambrésis (April, 1559) peace was restored, France agreeing to give up Calais in eight years. Six months after her accession the Catholic service was finally discontinued

in Elizabeth's private chapel. At first she would not take the title of head of the church, assuming that of its governess; but at a later period she asserted her supremacy arbitrarily. In France the English throne was claimed for Mary, queen of Scots; a foolish pretension, destined to have bloody consequences. Elizabeth early began to interfere with Scotch affairs, and the party of the reformation was enabled to triumph there through her aid. Pope Pius IV. sought to win the queen back to the church of Rome, but unsuccessfully. She restored the currency to sterling value in 1560, a reform that did much to promote the prosperity of her subjects. Aid in money, arms, and men was sent to the French Huguenots, and secret assistance to the Protestants of Flanders. When the queen of Scots sought a safe passage from France to Scotland, Elizabeth refused her request, and it is believed that she endeavored to seize her person. In 1563 parliament entreated the queen to marry, the question of the succession being one of much interest to all classes of her subjects, who were not yet free from the terror caused by the wars of the roses. Candidates for her hand continued to spring up at home and abroad. The most prominent Englishman who aspired to the honor was Henry Fitzalan, 18th and last earl of Arundel of that name. Though she was entreated to acknowledge Mary Stuart as her heirress presumptive, she would not do so, and the question was left open. She recommended Lord Robert Dudley as a husband to Mary Stuart, before he had been made earl of Leicester, though his object was to marry herself. She was offered the hand of Charles IX. of France, but though pleased with the offer she would not accept it. Another suitor of the highest rank was the archduke Charles, son of the German emperor. Leicester approved of this match. The fortunes of this new noble were rapidly rising, and though he and the queen occasionally fell out, they were soon reconciled, and to his increased gain. Their intimacy began early, in the days of Elizabeth's adversity, and lasted until the earl's death, causing scandalous stories to obtain currency. Her marriage with the favorite was expected daily. The marriage of Darnley and Mary Stuart annoyed her; and the birth of a son from that union caused alarm in England, as showing that the crown might pass to a Catholic. Parliament being summoned in October, 1566, one of the first acts of the commons was to vote that the bill for supplies should be accompanied by one for the settlement of the succession; for this Elizabeth hotly rebuked them. Even Leicester, whose schemes had been traversed by Cecil, was one of the leaders of the opposition on this occasion. In November she was waited upon by a deputation from both houses, and entreated to marry or to name a successor. She endeavored to reason them out of their obstinacy, and as to the succession, she said, they should have the benefit of her pray-

ers. The commons were stubborn, but the dispute was compromised, the queen taking half the money without naming her successor. The murder of Darnley led to the overthrow of Mary Stuart, and to her flight to England the next year (May, 1568), when she was made Elizabeth's prisoner. Mary submitted her case to be tried by English commissioners. Serious internal troubles now began, and those from without assumed a critical character. The asylum England afforded to those who fled from persecution in Flanders offended Spain. The English flag was insulted in the gulf of Mexico, and the English minister at Madrid badly treated. The queen retaliated by seizing treasure found in Spanish vessels which had taken refuge in English ports; and when Alva laid an embargo on Englishmen and their property, she arrested all the Spaniards in England, not even excepting the ambassador. She corresponded directly with Philip II., but that monarch took a high tone, and threatened war. The duke of Norfolk had become attached to Mary Stuart, and Elizabeth bade him be on his guard. He was arrested and imprisoned. The great northern rebellion broke out (1569), headed by the Catholic earls of Westmoreland and Northumberland, but was rapidly crushed by the earl of Sussex, and 800 of the rebels were executed. In 1570 the queen was excommunicated by Pope Pius V., and a copy of the bull was fastened on the gate of the episcopal palace of London by a Catholic named Felton, who was put to the rack and executed. After the failure of another attempt to bring about a marriage between the queen and the archduke Charles, it was proposed that she should marry the duke of Anjou, afterward Henry III. of France, and last of the Valois. When the council was informed of this, one of them observed that the duke was rather young for the queen (Anjou was 20 years old, Elizabeth 37), which enraged her. In this, as in all her negotiations of a similar character, she does not seem to have been sincere; but it was always a source of anger when any one of her suitors saw fit to marry some other lady. Cecil was now created Lord Burleigh, and made lord high treasurer, and Sir Thomas Smith principal secretary of state. Hatton now began to attract attention, being high in the queen's favor because of his personal accomplishments and beauty; and her reputation has been assailed on account of her fondness for him. For his good she despoiled the bishop of Ely of much church property, and wrote him a truculent epistle in three lines. The French marriage project halting, Anjou's mother proposed his younger brother Alençon in his place, who was Elizabeth's junior by 22 years, and as ugly in person as he was morally depraved. Subsequently the negotiation with Anjou was resumed. The emperor Maximilian II. offered the hand of his son Rudolph to the queen, who was more than old enough to be his mother. Henry of Navarre was also placed

at her disposal. She favored Anjou most, but finally rejected him, ostensibly on religious grounds. Philip II. was now engaged in a plan involving the assassination of Elizabeth, with which Norfolk and Mary Stuart had some connection. It was discovered, and Norfolk was executed. The Alençon marriage project was now resumed. Parliament passed a bill to put Mary Stuart to death, but Elizabeth would not give her consent to it. Meantime, in 1572 occurred the St. Bartholomew massacre, which made the English clamorous for the death of Mary. Elizabeth would not directly consent to this; but she agreed to a project for giving Mary up to her Scottish subjects, who it was understood would at once put her to death. In 1575 the Dutch offered their government to Elizabeth, whom they respected as descended from Philippa of Hainaut. She did not at first help them, and it was not till 1578 that she agreed to aid them with money and men, on conditions by which she could not lose anything. Ireland gave her great trouble, and the contest which was waged there by Lord Mountjoy was called by the Irish "the hag's war," in derision of the queen. Conspiracies began to multiply around her, naturally having Mary Stuart for their central figure. The Jesuits were conspicuous in these plots, in one of which the Spanish minister Mendoza was implicated, and forced to leave the country. Many persons were executed and others imprisoned. Philip Howard, earl of Arundel, son of the duke of Norfolk, was condemned to death, and died in the tower after a long imprisonment. An association to protect the queen against "popish conspirators" was formed by Leicester, and was converted into a statute by parliament, which actually prepared the way for the murder of Mary Stuart, should Elizabeth be assassinated in her name. The discovery of a conspiracy, in which Anthony Babington was a leading actor, which aimed at the simultaneous assassination of Elizabeth and the liberation of Mary, proved fatal to the latter. Her trial has been the subject of bitter discussion. She was convicted of complicity in the conspiracy, and was executed at Fotheringay, Feb. 8, 1587. Elizabeth professed great grief and anger at her execution. It is now pretty well established that her signature to Mary's death warrant was a forgery, and it is beyond doubt that it was sent to Fotheringay castle without her knowledge or sanction. Burleigh was the sender of it, and the forgery is supposed to have been perpetrated by the order or under the direction of Walsingham. Angry as she was, Elizabeth dared to punish no one but the secretary Davison, who was only a tool of the higher ministers; for not only had foreign affairs assumed a serious aspect, but the killing of Mary was unquestionably a popular act with the ruling classes and party. The Scotch people were enraged, and gladly would have assailed their old enemy; but nothing was done. The condition of France

left no room for fear on that side; but the pope and the king of Spain were active enemies. Sixtus V. anathematized Elizabeth, and proclaimed a crusade against her. Philip II. laid claim to the English crown, as legitimate heir of the house of Lancaster, in virtue of his descent from two daughters of John of Gaunt, who had been queens of Portugal and Castile. He made open preparations to enforce this claim, and the pope promised large conditional aid. Meantime, Drake ravaged the coasts of Spain, preyed on her commerce, and made a successful attack on the shipping in the harbor of Cadiz. The English were not backward in preparing to meet Philip's attack. All parties, Catholics and Puritans, as well as the rest of the people, showed a patriotic spirit. A fleet of 180 sail was got ready, commanded by Lord Howard of Effingham, Drake, Frobisher, and Hawkins. Two armies were raised, numbering over 60,000 men. The Spanish armada sailed May 29, 1588, but a storm compelled it to return; and it was not till the end of July that the two fleets met and joined battle near the English coast. After a series of actions that lasted several days the Spaniards were utterly routed, the elements greatly assisting the English, whose commanders had been seriously hampered by the indecision, perverseness, and avarice of the queen, who would not supply them with provisions or ammunition in anything like sufficient quantities. The country was thus delivered from present fear of invasion. In 1589 an expedition was sent to effect the liberation of Portugal; but though the army was landed and marched to the suburbs of Lisbon, the undertaking signally failed. Aid in men and money was sent to Henry IV. of France, then contending with Spain and the league, in 1590-'91. A parliament met in 1593, and the commons after some contention with her submitted to the sovereign. The decision of Henry IV. to abandon the Protestant faith annoyed Elizabeth, and she sought to influence his mind to remain firm, but ineffectually. A plot to poison her was detected, and her physician, Roderigo Lopez, a Spaniard of Jewish extraction, who had been in her service for some years, was executed for his part in it. Religious persecutions were now common, and several noted Puritans were put to death. The war with Spain was carried on with vigor, and Cadiz was taken in 1596, by a fleet and army commanded by Howard of Effingham and Essex. The latter was now the principal subject in England, but the infirmities of his temper prevented him from profiting fully by his position and the queen's regard. The court was full of intrigues, and Essex, the most generous and imprudent of men, was the victim of all who chose to play upon him. Philip II. having formed a plan to place his daughter on the English throne, Essex was sent to assail the Spaniards at home and on the ocean. He accomplished nothing, which offended the queen; but he soon recovered her favor, and was en-

abled to beard Burleigh, until the latter discovered that he was in correspondence with the king of Scotland. Henry IV., having resolved upon peace with Spain, to the anger of Elizabeth, offered to mediate a general peace. Burleigh favored this, and Essex took the other side. In a consultation on Irish affairs, in the royal closet, Essex turned his back contemptuously on the queen, who struck him on the head, and told him to "go and be hanged!" After a display of rashness and temper the earl left the presence. While efforts for a reconciliation were making, Burleigh died, Aug. 4, 1598. Six weeks later died Philip II. Essex returned to court, and shortly after was appointed lord deputy of Ireland, which was in a miserable state. The office was given less in love than in anger, and was the gift of enemies. A politician rather than a statesman, and a knight rather than a soldier, Essex failed entirely in Ireland, whence he returned without permission and entered upon a reckless course of action that ended in his death on the scaffold in 1601. Sir Robert Cecil, a son of Burleigh, was now Elizabeth's most powerful minister, and he was in correspondence with the king of Scotland. The queen sought to have Henry IV. visit her at Dover, he being at Calais, but he contented himself with sending M. de Rosny, later the duke de Sully, as his ambassador. Their interviews were interesting, and in the first she spoke of the king of Scotland as her successor, who, she said, would be king of Great Britain. This title originated with her. Another embassy was sent to England by Henry, and was well received. Elizabeth's last parliament met in October, 1601. It made great opposition to the oppressive monopolies she had granted, and she gracefully gave way. In the early part of 1603 (N. S.) she suffered from a complication of complaints, but the immediate cause of her death, which took place at Richmond, was a cold. She was buried April 28. Her reign is justly considered one of the most important England has known. "The Elizabethan age" is one of the most brilliant periods of English history, and the numerous statesmen, soldiers, scholars, and other intellectual personages who then existed, achieved for it a place in the world's annals that has never been surpassed.—The leading events in the life of Elizabeth are unquestioned. Of her personal character various and wholly diverse views have been formed. Fronde at the close of his elaborate history thus sums up his judgment respecting her: "Her situation from the very first was extremely trying. Her unlucky, it may be almost called culpable, attachment to Leicester made marriage unconquerably distasteful to her, and her disappointment gave an additional twist to her natural eccentricities. Circumstances more than choice threw her originally on the side of the reformation. She found herself compelled against her will to become the patron of heretics and rebels, in whose objects she had no

interest, and in whose theology she had no belief. She resented the necessity while she submitted to it, and her vacillations are explained by the reluctance with which each successive step was forced upon her, on a road which she detested. Her keenness of insight was not combined with any profound concern for serious things. She was without the intellectual emotions which give human character its consistency and power. One moral quality she possessed in an eminent degree: she was supremely brave. For 30 years she was perpetually a mark for assassination, and her spirits were never affected, and she was never frightened into cruelty. She had a proper contempt also for idle luxury and indulgence. She lived simply, worked hard, and ruled her household with rigid economy. But her vanity was as insatiate as it was commonplace. No flattery was too tawdry to find a welcome with her; and as she had no repugnance to false words in others, she was equally liberal of them herself. Her entire nature was saturated with artifice. Except when speaking some round untruth, she could never be simple. Obligations of honor were not only occasionally forgotten by her, but she did not even seem to understand what honor meant. Vain as she was of her own sagacity, she never modified a course recommended to her by Burghley without injury both to the realm and to herself. She never chose an opposite course without plunging into embarrassments, from which his skill and Walsingham's were barely able to extricate her. The great results of her reign were the fruits of a policy which were not her own, and which she starved and mutilated when energy and completeness were needed. That she pushed no question to extremities has been interpreted by the result into wisdom. She gained time by it, and her hardest problems were those which time alone could resolve satisfactorily. She wished only to reign in quiet till her death, and was contented to leave the next generation to settle its own difficulties. Mercy was the quality with which she was the most eager to be credited. Her tenderness toward conspirators was as remarkable as it was hitherto unexampled. Unlike her father, who ever struck the leaders and spared the followers, Elizabeth could rarely bring herself to sign the death warrant of a nobleman; yet without compunction she could order Yorkshire peasants to be hung in scores by martial law. She was remorseless when she ought to have been most forbearing, and lenient when she ought to have been stern; and she owed her safety and her success to the incapacity and the divisions of her enemies, rather than to wisdom and to resolution of her own."

ELIZABETH, queen of Spain, born at Fontainebleau, Nov. 22, 1602, died in Madrid, Oct. 6, 1644. She was the daughter of Henry IV. of France and Maria de' Medici, and was married to Philip, infante of Spain, Oct. 18, 1615.

Philip, having in 1621 succeeded to the crown as Philip IV., surrendered the administration to the count of Olivarez, and gave himself up to pleasure. Elizabeth made vain efforts to rouse him from his supineness, and to counteract the ruinous policy of his minister. In 1640, when Catalonia revolted, when Portugal separated from Spain, and French armies co-operated with the rebels, the queen appealed in person to the Castilians, and succeeded within a few weeks in raising an army of 50,000 men. Then, proceeding to the king's pleasure house of Buen Retiro, and holding her son by the hand, "Sir," said she, "this boy, our only son, is doomed to be the poorest gentleman in Europe, if your majesty does not forthwith dismiss a minister who has brought Spain to the verge of ruin." Olivarez was thereupon exiled, and Philip roused to momentary energy. Elizabeth broke off all relations with her own family, now become the worst enemies of Spain, and took into her own hands the administration of the kingdom, while Philip at the head of his armies vainly endeavored to retrieve his fortunes. She displayed equal wisdom and patriotism in her management of public affairs, allayed party strifes by her eloquent appeals, and set the example of generosity by sacrificing her jewels, and reducing her household expenses to the lowest figure. Her death was mourned as a national calamity.

ELIZABETH (*Élisabeth Philippine Marie Héléne*), madame, called Elizabeth of France, a French princess, sister of Louis XVI., born in Versailles, May 3, 1764, guillotined in Paris, May 10, 1794. At an early age she distinguished herself by charity and a taste for study, especially of botany. When the revolution broke out, she shared her brother's trials and misfortunes, evincing in all circumstances unfaltering firmness, courage, and sweetness of temper. On Oct. 5, 1789, she succeeded in preserving the lives of several of the royal body guard, threatened by the infuriated mob; in June, 1791, she accompanied her brother to Varennes, and sustained his spirit in their dangerous journey back to Paris; on June 20, 1792, when the populace broke into the Tuileries, her life was in danger from being mistaken for the queen; and in all the perils of that period she retained her wonted composure, and thought only of the safety of her brother and his family. She was incarcerated with them in the Temple, but was separated from the king on his trial before the convention, and afterward from the queen and the dauphin; and finally, although nothing could be adduced against her except her devotion to her brother, was sentenced to death by the revolutionary tribunal. She met her fate with the patience and intrepidity which had marked all her life.

ELIZABETH, *Saint*, called Elizabeth of Hungary, landgravine of Thuringia, daughter of Andrew II., king of Hungary, born in Presburg in 1207, died in Marburg, Germany, Nov. 19, 1231. At four years of age she was betrothed

to Louis, the eldest son of Hermann, landgrave of Thuringia, and according to the custom of the age was transferred to the household of her future husband, to be educated for her expected rank. The nuptials were celebrated when she had reached her 14th year; and continuing the religious practices for which she had early been remarkable, she enlisted the aid of her husband in the charitable works which engrossed her time. Louis joined the sixth crusade, but died before reaching the Holy Land, and his death at once changed the circumstances of the landgravine. Her infant son, Hermann, was declared incapable of succeeding to his father's rule; a party was organized in behalf of Henry, brother of the late landgrave; the castle was seized, and Elizabeth with her three children was turned out of her home without provision, money, or a change of raiment. After living some time in great destitution, subsisting now by charity and now by spinning, she was sheltered by her aunt the abbess of Kitzingen, until a more suitable asylum was found in a castle offered for her use by her uncle the bishop of Bamberg. At the intercession of the friends of the deceased landgrave, Henry recalled her to the Wartburg, and acknowledged the rights of her son; but afterward, in order to live in religious seclusion, and give herself wholly to works of charity, she took up her abode at Marburg in Hesse, where she spent the remaining three years of her life. She wore beneath her garment the haircloth of St. Francis, bound herself to obey the orders of her confessor, dismissed her favorite maids when she found herself loving them too well, devoted her liberal allowance entirely to the poor, and supported herself by spinning; she ministered to the most loathsome diseases, and even received lepers into her house. Her confessor, Conrad the legate, in compliance with her own wishes, subjected her to unusual penances. She was buried with great pomp in the chapel near the hospital which she had founded in Marburg, and the report of the frequent miracles wrought at her tomb induced Gregory IX. in 1235 to add her name to the list of saints. Her shrine was for ages one of the most famous of Europe, and the altar steps before it are worn hollow by the knees of pilgrims. Her life has been written by many authors, Catholic and Protestant, in many languages. No fewer than 38 published works and 13 MSS. relating her story are catalogued by Count de Montalembert, whose biography was translated by Mary Hackett (New York, 1854). The best Protestant life of St. Elizabeth is that of Justi (Zürich, 1797; new ed., Marburg, 1835). Her husband Louis IV. was also canonized, and their lives have been written together by Simon (Frankfort, 1854).

ELIZABETH CHARLOTTE, duchess of Orleans, born in Heidelberg, May 27, 1652, died at St. Cloud, Dec. 8, 1722. She was a daughter of the elector Charles Louis of the Palatinate, and

so homely that a duke of Courland who had been betrothed to her refused to marry her. After embracing Catholicism she became the second wife (Nov. 16, 1671) of Philip, duke of Orleans, brother of Louis XIV. At the French court she became distinguished for her integrity and intellect, as well as for her bluntness and eccentricity. She had a cordial hatred for Mme. de Maintenon, and opposed the marriage of her son (the future regent) with Mlle. de Blois, the king's natural daughter. Saint-Simon gives an amusing account of the energetic manner in which she displayed her feelings on the occasion by slapping her son in the face in the presence of the whole court. She often attended Louis XIV. to the chase, and the king enjoyed her wit and originality and esteemed her truthful character. Her predilection for the German language and literature increased the intercourse of French with German scholars, especially with Leibnitz, one of her principal favorites. Her claims to the Palatinate, however, proved disastrous for Germany, resulting in the devastation of that country by the armies of Louis XIV. (1688-'93). She wrote various memoirs, which have been several times translated and published in France. Her posthumous letters were also translated into French from the German, and published by P. G. Brunet in 1853; and into English, edited by Holland (2 vols., London, 1867-'72).

ELIZABETH CHRISTINA, queen of Prussia, born in Brunswick, Nov. 8, 1715, died Jan. 13, 1797. She was a princess of Brunswick-Bevern, and a niece of the empress of Germany, and was betrothed to the future Frederick the Great, March 10, 1732. Carlyle describes her as being at that time "an insipid, fine-complexioned young lady;" and Frederick, who was compelled to marry her by his father, and who was much opposed to the match, said of her in his letters to Grumkow: "She is not at all beautiful, speaks almost nothing, and is given to pouting." The marriage ceremony, however, was performed at Potsdam, June 12, 1733; and Carlyle says that, "with the gay temper of 18 and her native loyalty of mind, she seems to have shaped herself successively to the prince's taste, and growing yearly gracefuller and better-looking was an ornament and pleasant addition to his existence." Frederick made generous provision for her, and remarked in his will: "During my whole reign she has never given me the slightest cause of dissatisfaction, and her high moral character must inspire respect and love." She wrote several works in French.

ELIZABETH CITY, a S. E. county of Virginia, bordering on Chesapeake bay at the mouth of James river, bounded S. by Hampton Roads, and N. by Back river; area, 50 sq. m.; pop. in 1870, 8,303 of whom 5,471 were colored. It was one of the eight original shires into which Virginia was divided in 1634. It has a fertile soil, suitable for grain and potatoes.

The chief productions in 1870 were 10,820 bushels of wheat, 78,646 of Indian corn, 6,717 of oats, 15,024 of Irish and 15,879 of sweet potatoes. There were 280 horses, 107 mules and asses, 416 milch cows, 242 other cattle, 134 sheep, and 2,121 swine. Capital, Hampton.

ELIZABETH CITY, the county seat of Pasquotank co., North Carolina, on Pasquotank river, 20 m. from its mouth, and 40 m. S. of Norfolk, Va.; pop. in 1870, 930, of whom 421 were colored. It communicates with Norfolk by means of the river, which is navigable by small vessels, and of the Dismal Swamp canal. It has considerable trade, chiefly in lumber and other products of the pine, and contains a flour mill, four saw mills, three schools, a weekly newspaper, and several churches. Several confederate war vessels, which had escaped to this point after the occupation of Roanoke island by the Union forces, were captured or destroyed by a fleet under Commander Rowan, Feb. 10, 1862.

ELIZABETH FARNESE, queen of Spain, born Oct. 25, 1692, died in 1766. She was a daughter of Edward II., prince of Parma, and of the duchess Sophia Dorothea of Neuburg. Her ungainly appearance and headstrong disposition alienated from her the affections of her mother, and her education was neglected; but those who proposed her as a consort to Philip V. in the hope of making her their tool were greatly disappointed. The king of Spain on becoming a widower in 1714 resigned himself to the guidance of the French princess des Ursins, the favorite of his late beloved queen, and desired to follow her advice in the choice of a second wife. The princess selected Elizabeth on account of her apparent disqualification for an exalted position, and she was married to the king before the end of the year. But the first act of the new queen was to cause the dismissal of the princess, and she soon gained a complete mastery over her weak-minded husband and over the affairs of Spain. By her ambition and intrigues, and the great schemes of her minister, Cardinal Alberoni, Europe was thrown into confusion. Her eldest son Don Carlos obtained possession of the Two Sicilies. (See CHARLES III. of Spain.) Carlyle, in his "History of Frederick the Great," characterizes her as "a termagant, tenacious woman, whose ambitious cupidities were not inferior in obstinacy to Kaiser Karl's, and proved not quite so shadowy as his."

ELIZABETH ISLANDS, a group of 16 small islands, constituting the town of Gosnold, Dukes co., Mass., lying between Vineyard sound on the S. E. and Buzzard's bay on the N. W., and extending about 16 m. S. W. from Cape Cod, from which they are separated by a narrow channel known as Wood's Hole; pop. in 1870, 99. The principal islands, commencing at the north, are Naushon, about 8 m. long by 1 to 2 m. wide; Pasque, about 2 m. long; Nashawena, 3 m.; and Cuttyhunk, 2½ m.; they are separated from each other by narrow channels.

They were discovered in May, 1602, by Bartholomew Gosnold, after whom the town is named; he called the last mentioned island Elizabeth, in honor of the queen, a name since transferred to the group. On a rocky islet situated in a pond on this island a fort and storehouse were built, and the foundations of the first colony in New England were laid. Upon the return of Gosnold, about a month later, the colonists refused to remain, and the design of effecting a settlement was abandoned. Until 1864 the group formed a part of the town of Chilmark. The islands are noted for their beauty, have a delightful summer climate, and afford rare opportunities for fishing. On the E. shore of Naushon is Tarpaun cove, a harbor much frequented by wind-bound vessels on the passage from Boston to New York. This island, which is well wooded and contains an abundance of deer, was the favorite residence, in the early part of the century, of James Bowdoin, the diplomatist, who had here a fine mansion furnished with a large library, philosophical apparatus, and a picture gallery. It is now the property of a Boston gentleman, who has here his summer residence; and it is much resorted to by artists. Pasque and Cuttyhunk are occupied by New York clubs for boating and fishing purposes. About 2 m. N. and W. of Cuttyhunk and Nashawena is Penikese, comprising about 100 acres, formerly owned and occupied as a summer residence by John Anderson of New York, who in April, 1873, gave the island with the buildings and furniture (reserving the right of residing on a promontory of about 15 acres at the E. extremity) to Prof. Agassiz as a site for a summer school of natural history. He also gave to the institution the sum of \$50,000 as a fund for its maintenance. The school, known as the "Anderson School of Natural History," was opened in the summer of 1873, and is to be carried on in connection with the museum of comparative zoölogy at Cambridge.

ELIZABETH PETROVNA, empress of Russia, daughter of Peter the Great and Catharine I., born in 1709, died Jan. 5, 1762. After the death of her parents, her nephew, Peter II. (1727-'30), son of Alexis, and her cousin Anna Ivanovna (1730-'40), daughter of the elder brother of Peter the Great, successively occupied the throne of Russia, for which she showed little desire, the pleasures of love, as she used to say, being her supreme good. Anna appointed Ivan, son of Anthony Ulrich, duke of Brunswick, a child but a few months old, heir to the crown under the tutelage of his mother Anna, and the regency of Biron, the favorite of the empress. Thus Elizabeth was for a third time excluded from the throne of her father, but even her freedom was now menaced by the jealousy of the mother of the infant czar, who wished to get rid both of the regent and the princess, and advised the latter to take the veil. Under these circumstances her surgeon and favorite, Lestocq, brought about a con-

spiracy, which being seconded by the favor of the national Russian party, and the intrigues of the ambassador of Louis XV., terminated in a military insurrection, the overthrow of Anna and Ivan, and the proclamation of Elizabeth as empress (December, 1741). Anna and her husband, as well as many other victims, were punished by confinement, and the young prince was imprisoned in the fortress of Schlüsselburg, which he never again left; while the successive favorites of Elizabeth, like herself destitute of character and talent, ruled the court and Russia. Her vanity equalled her gross sensuality; but, though sometimes exceedingly cruel and barbarous, she often showed humanity, and even generosity. Subsequently some abler Russians obtained the management of affairs, among them Rumiantzeff, Bestuzheff, and Vorontzoff. Peter, son of her deceased elder sister Anna, duchess of Holstein-Gottorp, was appointed heir to the throne. A war with Sweden was successfully conducted, and terminated in the peace of Abo (1743). A plot against her was detected, and the parties implicated were severely punished. An army sent to assist the empress Maria Theresa against Frederick the Great contributed to the conclusion of the peace of Aix-la-Chapelle (1748). Influenced by Shuvaloff and Bestuzheff against Prussia, and mortified by a sarcasm of the witty Prussian king, Elizabeth allied herself against him with Austria and France in the seven years' war; and her armies, under Apraxin, Fermor, Soltikoff, and Buturlin, contributed not a little to the distresses of the almost isolated Prussian monarch. They won the battles of Gross-Jägerndorf and Kunersdorf, took Colberg, and even occupied Berlin. The death of the empress not only freed Frederick from a dangerous enemy, but also promised to give him in her successor, Peter III., an ardent supporter. The licentious disorder in her court lasted till her death. Razumovski, originally an obscure Cossack, successively her servant, chamberlain, and field marshal, finally became her secret husband, and is regarded as the father of three of her children. The founding of the university of Moscow and of the academy of fine arts at St. Petersburg are among her greatest merits. She patronized the fine arts, and carried on a correspondence with Voltaire, furnishing him with materials for the history of her father.

ELIZABETH STUART, queen of Bohemia, born in the palace of Falkland, near Edinburgh, Aug. 16, 1596, died at Leicester house, London, Feb. 13, 1662. She was a daughter of James I. of England, and a highly accomplished princess. She had many suitors, among whom the most eminent were the young king of Spain, Philip III., Charles Emmanuel I., duke of Savoy, and Frederick V., elector palatine; but as a Protestant Frederick was preferred. The marriage was celebrated with great pomp in Whitehall chapel, Feb. 14, 1613. To defray part of the expenses of the ceremonies the king levied

new taxes to the extent of £20,500. The total expense amounted to about £53,000, exclusive of the bride's portion of £40,000. Her husband was the head of the Protestant interest in Germany, and when in 1619 the crown of Bohemia was tendered to him by the insurgents, she urged his acceptance of it, with the remark that he should not have married a king's daughter if he had not the courage to become himself a king. Her entrance into Prague and her coronation were magnificent pageants, but her sovereignty soon came to an end. The imperialist forces advanced into Frederick's hereditary dominions and into Bohemia, and after the battle of Prague (Nov. 8, 1620) he and his queen were compelled to flee. A refuge was offered to them by her husband's uncle Maurice of Nassau, at the Hague, where most of her children were born. One of her sons was Prince Rupert, so well known in the history of the English civil wars. Her youngest child, Sophia, afterward electress of Hanover, and ancestress of the present English royal family, was born in 1630, soon after the birth of her nephew, Charles II. Elizabeth went to England in 1660, and resided for about six months in the house of Lord Craven, whose acquaintance she made after the death of her husband (1632), and with whom she lived on terms of the greatest intimacy. Her charms are celebrated by Sir Henry Wotton, in his famous lines beginning, "You meaner beauties of the night."

ELIZABETH OF VALOIS, or *Isabella*, queen of Spain, born at Fontainebleau, April 13, 1545, died in Madrid, Oct. 3, 1568. She was a daughter of Henry II. and Catharine de' Medici. By a treaty concluded at Angers in 1551 she was betrothed to Edward VI. of England, but the marriage was prevented by his premature death. By the preliminaries of the treaty of peace of Cateau-Cambrésis, her hand was assigned to Don Carlos, infante of Spain. The treaty was ratified April 3, 1559; but the father of Don Carlos, Philip II., being left a widower by the death of his wife, Queen Mary of England, and fascinated by a portrait which he had seen of the French princess, substituted himself for his son. After a wedding by proxy celebrated at Paris in June, she was united to Philip in February, 1560, the marriage ceremony being performed with great splendor at Toledo. Just before her death she was delivered of a daughter, who lived only to be baptized and was buried in the same coffin with her mother. Romantic accounts have been given of the relations between Elizabeth and Carlos, but Prescott in his "History of the Reign of Philip II." proves their groundlessness.

ELK, a name properly applied to the alpine division of the deer of the snowy regions, constituting the genus *alces* or *alce* (H. Smith). In this genus the muzzle is very broad, and covered with hair, except a small bare spot in front of the nostrils; the upper lip is 4 in. longer than the lower, and answers for pre-

hensile purposes; the neck is thick and short, and the throat somewhat maned in both sexes; the hair is coarse, thick, and brittle; the hind legs have the tuft of hair rather above the middle of the metatarsus; the horns in the males are broad and palmated; the tail is short. The nose cavity in the skull is very large, reaching posteriorly to a line over the front of the molars; the long intermaxillaries do not reach to the very short nasals. The horns have no basal snag, the first branch being considerably above the crown. The young are not spotted, but colored like the adult. Elks live in the woods in the northern parts of both continents, but the American is by some considered a distinct species from the European. The true American elk, or moose (as it is universally called here), *Alce Americanus* (Jardine), exceeds all other existing deer in size and strength, and unites to great speed remarkable powers of endurance; it is as large

American Elk (*Alce Americanus*).

as a horse, standing 5 ft. high at the shoulders, and measuring about 7 ft. from nose to tail; the length of the latter is about a foot; the weight of the horns varies from 45 to 70 lbs., and that of the animal from 8 to 12 cwt. The moose is an awkward, clumsy, and disproportioned creature, though from its size it possesses a certain majesty when seen amid the wild scenery of its favorite haunts. The head is too large in proportion to the body for any pretension to the symmetry usually seen in the deer family; the long, tumid, and movable upper lip gives to the face somewhat of an equine expression, and the heavy ears, more than a foot long, are decidedly asinine. Audubon says, "The head forcibly reminds us of that of an enormous jackass." The eyes are deep-seated and comparatively small; under the throat there is in both sexes a tuft of coarse bristly hair attached to a pendulous gland, which is most conspicuous in the young. The

horns are found in the males only, and require five years for their full development; they begin to sprout in April, and complete their growth in July; the first year they are about an inch long; the second year, 4 or 5 in., with perhaps a rudimentary point; the third year, about 9 in., each dividing into a round fork; in the fourth year they become palmated, with a brow antler and three or four points; and the fifth year they have two crown antlers and four or five points; after this one or two points are added annually, up to as many as 23, with an expanse sometimes of nearly 6 ft. to the outside of the tips, with the palm a foot wide within the points, and a circumference above the burr of 9 in. The horns diminish in size after the animal has passed the period of greatest vigor; in old and vigorous animals they are shed in December, but young animals sometimes carry them till March. The first inner branch begins about 9 in. from the base; the palms are often unlike on the right and left sides, and are channelled irregularly on both surfaces; their color is brownish yellow, with the ends yellowish white. The incisor teeth, six in the lower jaw only, are gouge-like and very white; the eyes are black; the nose, forehead, and upper lip yellowish fawn; the sides of the head yellowish brown; the general color above varies from blackish to ashy gray; below lighter, with a yellowish white tinge. In winter the color is darker, and in advanced age so dark as to merit the name given to it by H. Smith, "the American black elk;" the grayish are said to be the largest, reaching a height of 7 or 8 ft. In summer the hair is short and soft, in winter longer and very coarse, with a fine short wool next the skin. Moose are not uncommon in the northern parts of Maine, and in Canada, Nova Scotia, and Labrador, especially in winter. In summer they frequent lakes and rivers to free themselves from insect pests, and feed upon water plants and the tender branches of overhanging trees. In winter they retire to the elevated ridges abundantly provided with maple and other hard-wood trees, on the twigs and bark of which they feed. By the elongated upper lip they pull down the branches, which they hold with their fore legs until they are stripped of the twigs; they peel off the bark by including it between the hard pad on the roof of the mouth and the lower incisors. In winter they tread down the snow, forming what are called "yards," in which are generally found a male, female, and two fawns; as the trees are stripped they tread down fresh snow, and they are fond of going always in the same tracks. They prefer the twigs of the maple, willow, buttonwood, birch, and aspen, and grasses; in captivity they will eat the food of domestic cattle. Though their flesh is coarse, it is esteemed by hunters; the nose or muffle is a special favorite, being rich, gelatinous, and juicy, when cooked like calf's head; the steaks are juicy, often tender, but seldom fat;

the flesh of yearlings is always preferred; the tongue is much relished, as are the fatty appendages to the large intestines, by the hunters, who also consider the marrow warm from the shank bones an excellent substitute for butter. The moose trots, runs, and jumps with great speed, passing through seemingly impenetrable thickets and over broken ground without apparent effort; it swims well, with only the head and part of the neck above water; it is never seen like the reindeer on the ice, except from absolute necessity; when walking on untrodden snow its feet generally sink into it to the ground. Its sense of smell is very acute, and enables it to detect an enemy at a great distance; the breaking of the smallest twig is sufficient to startle it from its hiding place. The pairing season begins in September; during October the males become furious, fighting each other whenever they meet; they run noisily through the woods, and swim lakes and rivers in pursuit of the female; at this time it is dangerous for the hunter to approach, as they do not hesitate to attack him. The young are born in May, the first time one, and two annually afterward; the females are also very fierce in defence of their calves. The males are called bulls and the females cows. The proper times for hunting the moose are in March and September; in the latter month the animals are in their prime, and in the former they are most easily taken on account of the sharp crust impeding their progress through the snow. In hunting them in March, a few small curs are useful in worrying the animal and delaying it until the hunter comes up; it is useless to pursue them through soft snow, which offers no impediment unless it be deep, when the hunter can easily overtake them on snow shoes. Many are shot from canoes on moonlight nights in September; the hunter imitates the call of the male, which, angry at the supposed intrusion of a rival, rushes to the water's edge to fight him. Slip-nooses attached to strong saplings, bent down in the moose paths to the water, will occasionally entrap a victim. The most successful way is to start them from their yards, and pursue them over the snow. When wounded and brought to bay, they defend themselves fiercely, striking with their fore feet and horns; they will frequently turn upon the hunter when not wounded, and force him to fly for his life. Moose have been domesticated, and taught to draw carts and sledges, but during the rutting season they become perfectly intractable. Their geographical distribution is extensive; they have been found at the mouths of the Mackenzie and Coppermine rivers, on the E. slope of the Rocky mountains at the sources of Elk river, and in Oregon; on the E. coast they are found from Labrador to northern New England and New York, their southern limit seeming to be $43^{\circ} 30'$. As in all other deer of cold and mountainous regions, there is considerable diversity in the size of the body and

the horns of the moose, according to the abundance of food in the places inhabited by them. —The European elk (*A. malchis*, Ogilby) was once found between the 53d and 65th degrees of latitude in Prussia, Poland, Sweden, Norway, and Russia, but is rarely seen at present except in the most northern of these countries; it is also found in Asiatic Siberia. The appearance is the same as that of the moose; from its long legs and overhanging lips the old authors thought that it grazed walking backward. From the great height of the shoulders above the crupper its gait is awkward and shuffling, and when running fast the hind limbs are very wide apart; its joints crack at every step, with a sound which may be heard at a considerable distance; a part of the sound is said to be made by the hoofs striking against each other. According to Hamilton Smith, the Teutonic term *elend* (miserable) was applied to this animal from its supposed frequent attacks of

European Elk (*Alce malchis*).

epilepsy, while its falls are really attributable to its tripping itself up by treading on its fore heels, the elevated position of the nose, with the horns laid horizontally on the back, preventing it from seeing the ground distinctly before it. The European elk seems to attain a size equal to that of the moose, measuring 6 ft. high at the shoulder. The period of life is said to be about 20 years. Pennant states that elks were once used to draw sledges in Sweden, and that they could travel over 200 m. a day. Their hide makes excellent leather for belts and coverings for the feet. Though most authors have regarded the American and European elks as the same, Agassiz has described the former as distinct, with the specific name *lobatus*, from differences in the shape of the nose, the form and branching of the horns, and other points. Sir John Richardson (in the "Fossil Mammals" of the "Zoölogy of H. M. S. Herald") also considers the species distinct, calling the American *A. musca*; he compares

the skeletons carefully, and mentions, among other characters, that the breadth of the face at the most protuberant part of the maxillary bones is less in the American than in the European elk; if they be regarded as the same, the proper name would be *A. Americanus* (Jardine).—The name of elk is applied in this country to the wapiti (*cervus Canadensis*, Briss.), which should be called the American stag (see WAPITI); this name is also given by the British sportsmen in India to some of the rusa or sambo deer; so that it is necessary to consider the country of the animal before deciding on the meaning of the word "elk."—There are many fossil species called elks, as the fossil or Irish elk (*cervus giganteus*, Cuv.; *megaceros Hibernicus*, Owen), found in the diluvial strata of Europe, and especially in the peat bogs of Ireland; this species was of great size, with an enormous development of horns, which, resembling those of the elk in their broad palmations, differed in the size and low situation of the basal antlers; in other parts of the skeleton it resembled most the stags. Another species, found in the peat bogs and upper tertiary of France and Germany, seems to have been a gigantic fallow deer. The fossil elk described by H. de Meyer, from the diluvium of Europe, differed from the living animal in the form of its forehead. A fossil elk, allied to the wapiti, has been found in the United States, with the bones of the mastodon. The fossil *sivatherium*, described by Cantley and Falconer, from the Sivalik hills of the lower Himalaya range, seems in many respects to have resembled the moose; the form of the head and its size lead to the belief that it was elephant-like in the cellular prominences of its posterior portion; the face was short, and the nasal bones were raised into an arch over the external nostrils, indicating the probable existence of a trunk; we see the upper lip of the moose elongated also into a kind of prehensile proboscis; the head was also armed with two spreading horns, arising above and between the orbits; the molar teeth are entirely like those of ruminants; the anterior extremities (of which casts exist in the cabinet of the Boston society of natural history) indicate an animal of the size of a large elephant. This animal was undoubtedly a ruminant, with the pachyderm characters of a heavy form, short neck, and probably a proboscis; in like manner the ruminant moose departs from the deer family, and approaches the pachyderms (especially the *equidae*) in its movable elongated snout, long ears, and general shape.

ELK, a N. W. county of Pennsylvania, traversed by Clarion river, its branches, and some other small streams; area, about 700 sq. m.; pop. in 1870, 8,488. The surface is broken by many hills and rough mountain peaks, the principal of which is Elk mountain, in the S. part. The county is occupied chiefly by thick forests, and lumber is the most important article of export. Bituminous coal is found in

great abundance. The soil is better adapted to grazing than to the culture of grain. The Philadelphia and Erie railroad passes through it. The chief productions in 1870 were 6,372 bushels of rye, 12,234 of Indian corn, 61,573 of oats, 35,694 of potatoes, 6,182 tons of hay, and 108,730 lbs. of butter. There were 2,953 cattle and 3,031 sheep; 2 flour mills, 36 saw mills, 4 breweries, 3 tanneries, and 3 manufacturing of carriages. Capital, Ridgeway.

ELKHART, a N. county of Indiana, bordering on Michigan, and watered by St. Joseph's and Elkhart rivers, which unite within its borders; area, 467 sq. m.; pop. in 1870, 26,026. The surface is moderately uneven and diversified by prairies, oak openings, and several small lakes. The soil is fertile. The Lake Shore and Michigan Southern railroad, and the Warsaw branch of the Grand Rapids and Indiana railroad, pass through it. The chief productions in 1870 were 542,042 bushels of wheat, 268,538 of Indian corn, 108,430 of oats, 148,527 of potatoes, 20,888 tons of hay, 446,269 lbs. of butter, and 71,453 of wool. There were 7,204 horses, 6,370 milch cows, 7,768 other cattle, 24,147 sheep, and 14,197 swine; 7 manufacturing of agricultural implements, 3 of boots and shoes, 5 of bricks, 13 of carriages and wagons, 13 of barrels and casks, 12 of furniture, 6 of iron castings, 1 of wrapping paper, 5 of woollen goods, 10 flour mills, 2 planing mills, and 20 saw mills. Capital, Goshen.

ELKHART, a town of Elkhart co., Indiana, at the confluence of the St. Joseph's and Elkhart rivers, on the Lake Shore and Michigan Southern railroad, about 80 m. E. by S. of Chicago; pop. in 1870, 3,265. It is the principal shipping point for the county. The water power is good, and the town contains several saw mills, flouring mills, and a paper mill, besides extensive machine shops of the railroad company. There are a national bank, a school building, three weekly newspapers, two monthly periodicals (one German), and several churches.

ELKO, the N. E. county of Nevada, bordering N. on Idaho and E. on Utah; area, 13,800 sq. m.; pop. in 1870, 3,447, of whom 439 were Chinese. The sources of the Humboldt and Owyhee rivers are in this county. The land is high and much of it suitable for farming and grazing. Silver is mined to some extent, and gold, copper, and lead are found. Three quartz mills for the production of silver are in operation. The chief productions in 1870 were 4,535 bushels of wheat, 30,560 of barley, 9,841 of potatoes, and 406 tons of hay. Capital, Elko, a station on the Central Pacific railroad.

ELLENBOROUGH. **I.** Edward Law, baron, chief justice of the court of king's bench in England, born at Great Salkeld, Cumberland, Nov. 16, 1750, died in London, Dec. 13, 1818. He was a son of Edmund Law, bishop of Carlisle, and was educated at the Charterhouse school in London, and at St. Peter's college, Cambridge. His abilities as a lawyer and speaker were first displayed in the trial of Warren

Hastings in 1788-'95, in which he was leading counsel for the defendant. In 1801 he was appointed attorney general, and in 1802 he succeeded Lord Kenyon as chief justice of the king's bench, on which occasion he was elevated to the peerage as Baron Ellenborough. He retired from the bench in November, 1818.

II. Edward Law, first earl of, an English statesman, son of the preceding, born Sept. 8, 1790, died Dec. 22, 1871. He was educated at Eton and at St. John's college, Cambridge, where he graduated in 1809. Shortly afterward he entered parliament as a member for the now disfranchised borough of St. Michael's. In 1814 he received from his father the sinecure office of clerk of the court of queen's bench, worth £7,000 a year, which he held until his death, receiving in all about £400,000 without having any duty to perform. He succeeded to the peerage as second baron in 1818, and upon the accession of the duke of Wellington to office, in 1828, he was appointed lord privy seal. During the administration of Sir Robert Peel, in 1834-'5, he became president of the board of control and first commissioner of Indian affairs, an office to which he was reappointed in September, 1841. In the following month he was appointed to succeed Lord Auckland as governor general of India. He arrived in Calcutta in February, 1842, and in April, 1844, he was recalled by the board of East India directors, contrary to the wishes of the cabinet. During his administration Scinde was annexed to the British dominions, and Gwalior reduced to subjection; but he was charged with excessive tenderness for the native troops, to the neglect of the employees in the civil service; with issuing proclamations which seemed to sanction idolatry; and with other questionable acts in his official capacity. Upon his return to England, however, he was created an earl, and in January, 1846, was appointed first lord of the admiralty, which office he held for only six months. He remained out of office until the formation of the Derby cabinet in February, 1858, when he again became president of the board of control. Early in May a despatch from him to Lord Canning, governor general of India, strongly condemnatory of the proclamation confiscating the property of the natives of Oude, was made public, and excited so much animadversion that on the 11th, after vindicating his course in a speech, he announced that rather than expose his colleagues to the censure of parliament he had resigned his office. His first wife died childless; from his second, who bore him a son who died in infancy, he was divorced. He was succeeded by his nephew, Charles Edmund, born in 1820. **III. Jane Elizabeth**, second wife of the preceding, born about 1807. She was a daughter of Admiral Digby, was married to the earl of Ellenborough in 1824, and in 1830 eloped with Prince Felix Schwarzenberg, then Austrian ambassador to England, and her marriage was dissolved by special act of parliament. She

was soon abandoned by her paramour; but by the terms of her divorce she was in possession of a large income. For years she led a gay and abandoned life in Italy and elsewhere. She was in time married to a Greek count, from whom she separated. After a while she set out on a journey to the East, and going from Palmyra to Damascus, her guard was commanded by a petty Bedouin sheik named Medjuel. She took a fancy to him, and upon their arrival at Damascus told him that she intended to marry him. He ran away; she followed him into the desert, caught him, and was married to him by the Bedouin ceremony, without other witnesses than his Arab companions. In his name she purchased a country house and gardens outside the walls of Damascus, and made it her home for a part of the year, the remainder being passed in the tent of her Bedouin husband. These events occurred about 1850. An account of a visit to her residence in Damascus in 1855 is given by Mr. W. C. Prime in his "Tent Life in the Holy Land" (New York, 1857).

ELLERY, William, one of the signers of the Declaration of Independence, born in Newport, R. I., Dec. 22, 1727, died there, Feb. 15, 1820. He graduated at Harvard college in 1747, and became a merchant in Newport; was naval officer of the colony of Rhode Island; and in 1770 he commenced the practice of the law. In May, 1776, he was elected to the memorable congress of that year as one of the delegates from Rhode Island, and with his colleague, Stephen Hopkins, he set his name to the Declaration of Independence. He remained in congress till 1786, with the exception of the years 1780 and 1782; and as a member of the marine committee, and subsequently of the board of admiralty, he exercised considerable influence. The plan of fire ships to be fitted out at Newport has been attributed to him. In April, 1786, he was elected by congress commissioner of the continental loan office for the state of Rhode Island, and in 1790 was appointed by Washington collector of Newport, an office which he held until his death. A biography of him by his grandson, Edward T. Channing is contained in Sparks's "American Biography," vol. vi.

ELLESMERE, Francis Egerton, earl of, an English nobleman, born in London, Jan. 1, 1800, died there, Feb. 18, 1857. He was the second son of the first duke of Sutherland, and until the death of his father was known as Lord Francis Leveson-Gower. He was educated at Eton, and at Christchurch, Oxford, left the university in 1820, and in 1822 entered parliament as a liberal conservative and a supporter of Canning, and became one of the earliest and most earnest advocates of free trade. He also supported the project for establishing the university of London, and on one occasion carried a motion through the house of commons for the endowment of the Roman Catholic clergy of Ireland. In 1827 he was a lord of the trea-

surey; from January, 1828, to July, 1830, he was chief secretary for Ireland; and from July to November, 1830, he was secretary at war. In 1833, upon the decease of his father, he came into possession of the immense estates of the late duke of Bridgewater, and of the picture gallery, valued at £150,000, which had been bequeathed to the duke of Sutherland, with reversion to his second son; on which occasion he assumed the name of Egerton in the place of his patronymic of Leveson-Gower. In 1835 he was elected member of parliament for South Lancashire, and represented that constituency till 1846, when he was raised to the peerage as earl of Ellesmere, after which he retired from active political life. In 1841 he was elected rector of the university of Aberdeen. While a student at the university he printed a volume of poems for private circulation; but his first public appearance as an author was in 1824, when he published a translation of "Faust," with versions of popular lyrics from the works of Goethe, Schiller, and other German poets. He subsequently produced "Mediterranean Sketches" (London, 1843), containing "The Pilgrimage," a poem which records the author's tour in Palestine; "The two Sieges of Vienna by the Turks" (1847); "Guide to Northern Archæology" (1848); "Life and Character of Wellington" (1852); and a number of poems and plays printed for private circulation. "The Pilgrimage," after having been withheld from general circulation for many years, was republished in 1856 with a number of additional poems. In 1853 Lord Ellesmere visited the United States.

ELLET, Charles, jr., an American engineer, born at Penn's Manor, Pa., Jan. 1, 1810, died at Cairo, Ill., June 21, 1862. He planned and built the first wire suspension bridge in the United States, that across the Schuylkill at Fairmount, Philadelphia, the first suspension bridge across the Niagara below the falls, and the first one at Wheeling, Va. He was employed in many other important engineering works, and in 1846-'7 was president of the Schuylkill navigation company. During the civil war he urged upon the government the construction of steam rams for use on the large rivers of the west, and after his plans had been rejected by the navy department he presented them to the secretary of war, by whom they were approved. He was commissioned as colonel of engineers, and converted several powerful light-draught steamers on the Mississippi river into rams. With these he engaged in the naval battle off Memphis, June 4, 1862, and sank or disabled several of the confederate vessels. During the battle he was wounded above the knee by a musket ball, from the effects of which he died. He was the author of "The Mississippi and Ohio Rivers," containing plans for their improvement and the protection of the delta (8vo, Philadelphia, 1853), &c.

ELLET, I. William Henry, an American chemist, born in New York about 1804, died there,

Jan. 26, 1859. He graduated at Columbia college in 1824. While pursuing his medical studies he gained a gold medal for a dissertation on the compounds of cyanogen. In 1832 he became professor of experimental chemistry in Columbia college, and in 1835 of chemistry, mineralogy, and geology in the South Carolina college. In 1848 he returned to New York, where he resided until his death. The legislature of South Carolina presented him with a service of silver plate for the discovery of a new and cheap method of preparing gun cotton. During the last five years of his life he was consulting chemist of the Manhattan gas company of New York. **II. Elizabeth Fries-Luamiss**, an authoress, wife of the preceding, born at Sodus Point, N. Y., in 1818, died in New York, June 3, 1877. She published a volume of poems (1835), "Scenes in the Life of Joanna of Sicily" (1840), "Characters of Schiller" (1841), "Women of the American Revolution" (1848), "Evenings at Woodlawn," "Family Pictures from the Bible" (1849), "Domestic History of the American Revolution" (1850), "Watching Spirits" (1851), "Pioneer Women of the West" (1852), "Novellettes of the Musicians" (1852), "Summer Rambles in the West" (1853), "Women Artists in all Ages and Countries" (1861), "Queens of American Society" (1867), and "Court Circles of the Republic" (with Mrs. R. E. Mack, 1869). She also edited "The Practical Housekeeper," and contributed largely to periodicals.

ELLICOTT, I. Andrew, an American astronomer and civil engineer, born in Bucks co., Pa., Jan. 24, 1754, died at West Point, N. Y., Aug. 28, 1820. His father, a Quaker, having united with a brother in the purchase of a large tract of wild land on the Patapsco river, in 1774 founded the town of Ellicott's Mills (now Ellicott City), in Maryland, where the younger days of his son were devoted to the study of the sciences and practical mechanics. His scientific attainments early attracted attention, and he enjoyed the friendship and confidence of Washington, Franklin, and Rittenhouse. At various times he was appointed commissioner for marking parts of the boundaries of Virginia, Pennsylvania, and New York. About 1785 he removed to Baltimore, and represented that city in the state legislature. In 1789 he was appointed by Washington to survey the land lying between Pennsylvania and Lake Erie, and during that year he made the first accurate measurement of the Niagara river from lake to lake, with the height of the falls and the descent of the rapids. In 1790 he was employed by the government to survey and lay out the federal metropolis. In 1792 he was made surveyor general of the United States, and in 1795 he superintended the construction of Fort Erie at Presque Isle (now Erie, Pa.), and was employed in laying out the towns of Erie, Warren, and Franklin. In 1796 he was appointed by Washington commissioner on behalf of the United States, under the treaty of

San Lorenzo el Real, to determine the southern boundary separating the United States territory from the Spanish possessions. The results of this service, embracing a period of nearly five years, appear in his "Journal" (4to, with 6 maps, Philadelphia, 1803). Upon the completion of this service he was appointed by Gov. McKean of Pennsylvania secretary of the state land office, from which he retired in 1808, and in 1812 he became professor of mathematics at West Point, a post which he occupied till his death. In 1817, by order of the government, he went to Montreal to make astronomical observations for carrying into effect some of the articles of the treaty of Ghent. He was an active member of the American philosophical society, and maintained correspondence with the learned societies of Europe; but with the exception of his "Journal," contributions to philosophical societies, and a few other writings, his works are yet in manuscript.

II. Joseph, brother of the preceding, born in Pennsylvania, died in Batavia, N. Y., in 1826. In 1790 he assisted his brother Andrew in laying out the city of Washington, and in 1791 was appointed to run the boundary line between Georgia and the Creek Indians; and for a long period, embracing the most active portion of his life, he was engaged in the service of the Holland land company. He was identified with the great public improvements of the state of New York.

ELLCOTT, Charles John, an English prelate and author, born at Whitwell, near Stamford, April 25, 1819. He graduated at St. John's college, Cambridge, in 1841, and was rector of Pilton, Rutlandshire, from 1848 to 1858, when he succeeded Dr. Trench as professor of divinity in King's college, London. In 1860 he became Hulsean professor of divinity at Cambridge, in 1861 dean of Exeter, and in 1863 bishop of Gloucester and Bristol. His works are: "Treatise on Analytical Statics" (1842); "History and Obligation of the Sabbath" (1844); "Critical and Grammatical Commentaries" on the epistles of St. Paul to the Galatians, Ephesians, Philippians, Colossians, Thessalonians, and Philemon, and on the "Pastoral Epistles" (1854-'61); "Lectures on the Life of our Lord Jesus Christ" (1860); and "Considerations on the Revision of the English Version of the New Testament" (1870). He has also published many addresses, lectures, sermons, and charges. His commentaries are highly esteemed, and are used as text books in English and American seminaries.

ELLCOTT CITY (formerly **ELLCOTT'S MILLS**), the county seat of Howard co., Maryland, situated on both sides of the Patapsco river, partly in Baltimore co., about 10 m. W. of the city of Baltimore and on the Baltimore and Ohio railroad; pop. in 1870, 1,722, of whom 355 were colored. The water power is excellent, and supplies several flour mills and manufactories. The town is the seat of St. Charles college (Roman Catholic), organized in 1848, which in

1871 had 12 professors and instructors, 180 students, and a library of 4,000 volumes. Rock Hill college, also a Roman Catholic institution, organized in 1857, had in 1872 22 professors and instructors, 156 students, and a library of 6,800 volumes. The town was settled in 1774 by the brothers Andrew and John Ellicott, whose large flouring mills here at one time held precedence in extent and perfection over all similar establishments in the country. It was incorporated under its present name in 1867.

ELLIOT, George Thomson, an American physician, born in New York, May 11, 1827, died there, Jan. 29, 1871. He received his academic education at Columbia college, graduated in medicine at the university of New York in 1849, and subsequently spent three years in professional study abroad, during which period he was resident interne in the lying-in hospital of Dublin, and of the royal maternity hospital in Edinburgh. Upon his return in 1852 he was made resident physician to the New York lying-in asylum, and in 1854 attending physician to the Bellevue hospital. In 1858 and 1859 he was lecturer on operative midwifery in the college of physicians and surgeons, New York, and in 1861 became professor of obstetrics and diseases of women and children in the Bellevue hospital medical college, an institution of which he was one of the founders. He wrote much for medical journals, but his principal work was "Obstetric Clinic" (1868), giving the results of midwifery cases selected from his own practice. On June 26, 1870, he had a severe attack of apoplexy with hemiplegia, which came on while he was engaged upon a case of operative midwifery. From this he partially recovered, but on Jan. 28, 1871, he had a second attack, which proved fatal.

ELLIOTSON, John, an English physician and physiologist, born in London about 1790, died there, July 29, 1868. He was educated at Jesus college, Cambridge, studied medicine and surgery in Edinburgh, and at St. Thomas's and Guy's hospitals in London, and in 1822 was elected physician to the former institution. Subsequently he became lecturer on the practice of medicine in St. Thomas's hospital, and in 1831 professor of the principles and practice of medicine and of clinical medicine in University college, London, in connection with which three years later he established a hospital, when he resigned his professorship at St. Thomas's. As a lecturer he obtained great popularity, though in attempting to reform the old routine of the hospitals he incurred the hostility of many of the profession. He was the founder and president of the phrenological society, and the president of the royal medical and surgical society. He had many disputes with members of the profession with regard to the use of certain remedies, now established, and advocated mesmerism as a remedy in some diseases and an agent for allaying pain in surgical operations. The unwill-

ingness of his medical colleagues and of the council of the university to allow the mesmeric cure to be applied to the hospital patients induced him, in December, 1838, to sever his connection with University college; and in 1849 a mesmeric hospital was founded, of which he was physician. A mesmeric journal, called "The Zoist," was also established by him. His principal contributions to medical science are: a translation with voluminous notes of Blumenbach's "Physiology" (1817); "Lectures on Diseases of the Heart" (1830); "Human Physiology" (1835-'40); "Principles and Practice of Medicine" (1840); and "Surgical Operations without Pain" (1843).

ELLIOTT, an E. county of Kentucky, drained by Little Sandy river and the N. fork of the Licking; pop. in 1870, 4,433, of whom 22 were colored. The surface is broken by hills containing coal and iron ore. The chief productions in 1870 were 8,261 bushels of wheat, 171,889 of Indian corn, 21,600 of oats, and 12,024 of potatoes. There were 908 horses, 1,083 milch cows, 2,129 other cattle, 6,835 sheep, and 6,493 swine. Capital, Sandy Hook, or Martinsburg.

ELLIOTT, Charles, D. D., an American clergyman, born at Greenconway, county Donegal, Ireland, May 16, 1792, died at Mount Pleasant, Iowa, Jan. 6, 1869. In his youth he became a member of the Wesleyan Methodist society, and soon after began a course of study preparatory for the ministry. In 1815 he emigrated to America, and went to Ohio, where he was received into the travelling connection of the Ohio conference in 1818. In 1822 he was appointed superintendent of the mission among the Wyandot Indians at Upper Sandusky, was subsequently for five years presiding elder of the Ohio district, and was then elected professor of languages in Madison college, Uniontown, Pa., where he remained four years. In 1831 he was stationed in Pittsburgh, and was subsequently presiding elder of that district. While serving in this capacity he was chosen editor of the "Pittsburgh Conference Journal," and afterward of the "Western Christian Advocate," at Cincinnati, where he remained till 1848. He again entered the regular work of the ministry, but in the general conference of 1852 he was re-elected editor of the "Western Advocate." From 1857 to 1860 he was professor of Biblical literature and president of the Iowa Wesleyan university. He was then appointed editor of the "Central Christian Advocate" at St. Louis, Mo., and during the civil war strongly sustained the cause of the Union. After its close he was again connected with the Iowa university till 1866. His chief works are: "Treatise on Baptism" (1834); "Delineation of Roman Catholicism" (2 vols. 8vo, 1851); "Life of Bishop Roberts" (1853); "History of the Great Secession from the Methodist Episcopal Church" (1855); "Political Romanism" (1859); "Reminiscences of the Wyandotte

Mission;" "Southwestern Methodism;" and two works against slavery.

ELLIOTT, Charles Loring, an American painter, born in Scipio, N. Y., in December, 1812, died in Albany, Aug. 25, 1868. He was for some time employed in a country store, but that occupation being distasteful to him, his father, who was an architect, allowed him to study drawing with a view to that profession. Elliott went to New York and became a pupil of Trumbull, and subsequently of Quidor, a painter of fancy pieces, with whom he remained long enough to acquire a knowledge of the technicalities of his art. His chief employment for some time was copying prints in oils, and he afterward attempted portraits. Some of his paintings representing scenes from Irving's and Paulding's works attracted attention. After about a year's residence in New York he returned to the western part of the state, where he practised portrait painting for about ten years. Returning to New York in 1845, he established himself there as a portrait painter, and soon rose to the head of his profession. He painted about 700 portraits, many of them of prominent persons, and all remarkable for fidelity of likeness and vigorous coloring. Not long before his death he established his studio and residence in Albany.

ELLIOTT, Charles Wyllys, an American author, born in Guilford, Conn., May 27, 1817. He is a lineal descendant in the fifth generation from Eliot the "Indian Apostle." After some years spent in mercantile life in the city of New York, he in 1838-'9 studied horticulture and landscape gardening with A. J. Downing at Newburgh, and from 1840 to 1848 practised those pursuits at Cincinnati. He then returned to New York and engaged in mercantile business, but devoted attention to literary pursuits. He was one of the founders and first trustees of the "Children's Aid Society" in 1853. In 1857 he was appointed one of the commissioners for laying out the Central park in the city of New York. He has published "Cottages and Cottage Life" (1848); "Mysteries, or Glimpses of the Supernatural" (1852); "St. Domingo, its Revolution and its Hero, Toussaint l'Ouverture" (1855); "The New England History, from the Discovery of the Continent by the Northmen, A. D. 986, to 1776" (2 vols., 1857); "Remarkable Characters and Places in the Holy Land" (1867); and "Wind and Whirlwind, by Thom Whyte" (1868). He has also been a frequent contributor to periodicals, and is the author of several novels published anonymously. He is now (1874) a resident of Cambridge, Mass., and manager of the "Household Art Company" of Boston.

ELLIOTT, Ebenezer, an English poet, called "the corn law rhymers," born at Masborough, near Rotherham, Yorkshire, March 17, 1781, died near Barnsley, Dec. 1, 1849. His father, who was employed in a foundry near Masborough, was a dissenter of what was called the Berean sect, an occasional preacher, and a forci-

ble political speaker of the ultra radical type. Young Elliott received the education usually afforded to boys of his condition, but at school was noted for little else than dulness and laziness. He was unable to master the rudiments of grammar or arithmetic, and often gratified an instinctive love for nature and solitude by stolen rambles in the meadows and woodlands. His father consequently set him to work in the foundry. He was beginning to fall into dissipated habits when the perusal of a treatise on botany revived his love of nature, and he became an industrious collector of botanical specimens. He also procured access to a small library of the old divines and poets, and in his 17th year produced his first published poem, "The Vernal Walk," which was followed by "Night," "Wharrelife," "Love," and others. His powers increased with each new work, and he attracted the notice of Southey, to whose kind offices he was accustomed to refer with affection and gratitude. He had meanwhile worked steadily till his 23d year in the foundry, which his father had purchased on credit, and having married set up at Rotherham in the iron business on his own account, but was unsuccessful. At 30 years of age he became an earnest advocate of the laboring classes. The corn laws in particular struck him as unjust, and upon his failure in business he attributed his misfortunes to their influence. In 1821 he made another venture as an iron merchant in Sheffield, with a borrowed capital of £100, and was soon embarked in a lucrative business. He now commenced his "Corn Law Rhymes," which were written with the sole purpose of procuring the repeal of the obnoxious laws. At first published in a local paper and afterward collected in a single volume, these poems brought Elliott into notice. "The Ranter," which succeeded, was a long poem in a similar vein. In 1829 appeared his "Village Patriarch," the best of his larger pieces. In 1833 he commenced a complete edition of his works, which appeared during the next two years, and for the first time made generally known many of the author's poems not of an exclusively political character. Several other editions appeared in the course of his life, and to the last he continued to write verses, chiefly for the periodical press, and occasionally spoke in support of his peculiar views. The commercial panic of 1837 entailed serious pecuniary losses upon him, but by careful management he was enabled in 1841 to retire from business with a competency and settle at a villa near Barnsley, where he passed the last years of his life in pleasant seclusion. Soon after his death was published "More Prose and Verse by the Corn Law Rhymer" (2 vols., London, 1850), and his "Autobiography," in the "Athenæum" (January, 1850).

ELLIOTT, Jesse Duncan, an American naval officer, born in Maryland, July 14, 1782, died in Philadelphia, Dec. 18, 1845. He entered the service as a midshipman in April, 1804, and was promoted to a lieutenant April 23,

1810. In 1812 he was attached to the command of Commodore Isaac Chauncey at Sackett's Harbor, and on the declaration of war against Great Britain was sent by him to the upper lakes to purchase vessels, and make other preparations for the creation of a naval force in those waters. While he was at Black Rock, engaged in this service, two armed British brigs, the *Detroit* and *Caledonia*, anchored, Oct. 7, 1812, near the opposite shore under the guns of Fort Erie. A boat expedition was organized under Elliott's command, and the vessels were boarded and carried with but slight loss a little after midnight, Oct. 8. The *Caledonia* was safely brought over to the American side; but the *Detroit* was compelled to drop down the river, passing the British batteries under a heavy fire, and afterward was burned by the Americans, most of her stores having first been removed. For this exploit Elliott was voted a sword by congress. In July, 1813, he was promoted to the rank of master commandant, and appointed to the *Niagara*, a brig of 20 guns, on Lake Erie. In Perry's engagement with the British squadron, Sept. 10, 1813, Elliott was second in command, and a gold medal was voted him by congress for his conduct on the occasion. In October he succeeded Perry in command on Lake Erie, and in 1815 he commanded the Ontario sloop of war, one of the squadron of Commodore Decatur employed against Algiers. He was promoted to the rank of captain, March 27, 1818, and till 1824 was engaged in selecting sites for dockyards, lighthouses, and fortifications on the coast of North Carolina. From 1829 to 1833 he was in command of the West India squadron, and in the latter year of the Charlestown navy yard. Afterward he commanded for several years the Mediterranean squadron. His conduct in this position did not meet the approval of the executive, and resulted in his trial by court martial in June, 1840, and suspension from duty for four years. In October, 1843, the period of his suspension which then remained was remitted by the president, and he was appointed to the command of the Philadelphia navy yard.

ELLIOTT, I. Stephen, an American naturalist, born in Beaufort, S. C., Nov. 11, 1771, died in Charleston, March 28, 1830. He graduated at Yale college in 1791, and two years later was elected a member of the legislature of South Carolina, a position which he retained until the establishment of the "Bank of the State" in 1812, of which he was chosen president. He retained this office till his death. His leisure was devoted to literary and scientific pursuits, and he cultivated the study of botany with enthusiasm. In 1813 he was instrumental in founding the literary and philosophical societies of South Carolina, of each of which he was president. He lectured gratuitously on his favorite science, and was for some time chief editor of the "Southern Review," to which he contributed a number of articles. In

1825 he aided in establishing the medical college of the state, and was elected one of the faculty, and professor of natural history and botany. He is the author of "The Botany of South Carolina and Georgia" (2 vols. 8vo, Charleston, 1821-'4), in the preparation of which he was assisted by Dr. James McBride, and left a number of works in manuscript. His collection in the several departments of natural history was at the time of his death one of the most extensive in the country. The degree of L.L. D. was conferred upon him by Yale and Harvard colleges: **II. Stephen**, son of the preceding, bishop of the Protestant Episcopal church for the diocese of Georgia, born at Beaufort, S. C., Nov. 13, 1805, died in Savannah, Dec. 21, 1866. He graduated at Harvard college in 1824, practised law in Charleston and Beaufort till 1833, and was ordained a deacon in 1835, and a priest in 1836, soon after which he became professor of sacred literature in the South Carolina college. In 1840 he was elected bishop of Georgia.

ELLIOTT, William, an American author and politician, born in Beaufort, S. C., April 27, 1788, died there in February, 1863. He was entered in Harvard college at the age of 18, but ill health compelled him to return home before the completion of his studies. For many years he devoted himself to the management of his estates, and served in both branches of the state legislature. During the nullification crisis in South Carolina in 1832 he was a senator in the state legislature, but resigned upon being instructed by his constituents to vote to nullify the tariff law. He afterward participated less frequently in public affairs, his letters against secession signed "Agricola," and published in 1851, being among his latest expressions of opinion on political subjects. He contributed largely to the periodical press of the south. He published "Address before the St. Paul's Agricultural Society" (1850), "Fiesco," a tragedy (1850), "Carolina Sports by Land and Water" (1856), and several occasional poems.

ELLIPSE, an oval figure produced from the section of a cone by a plane which cuts both sides of it in an oblique direction. It may also be obtained by letting the shadow of a circle fall on a plane; or it may be drawn by driving two pins into a board to mark the foci, putting a loose loop of inelastic thread over them, and drawing the curve with a pencil placed inside the loop and stretched out as far as the loop will allow. Instruments to describe an ellipse are called ellipsographs or elliptographs. The foci of an ellipse are the given points around which another point is conceived to move in such a manner that the sum of their distances from it is always the same; the line thus described is an ellipse. The centre of an ellipse is the point which bisects the straight line between the foci. The distance of either focus from the centre is called the eccentricity. A straight line passing through the centre, and

terminated both ways by the ellipse, is called a diameter. The diameter which passes through the foci is called the transverse axis, also the greater axis. The ellipse is the projection of a circle; the curve which is everywhere equally distant from the sum of the foci is an ellipse. Kepler announced the law that planetary orbits are ellipses, and upon the three simple formulas which he laid down for the solution of this problem is based all that has been done since to determine the movements of the planets. The ellipse, and the ellipsoid, which is a solid figure all plane sections of which are ellipses or circles, enter largely into mechanical contrivances. The method given above of describing an ellipse is applied in machines to turn wood and other substances into elliptic forms. An instrument similar to the elliptograph is employed for engraving ellipses on metals, and for dividing these ellipses accurately, so as to give the perspective representation of a circle divided into equal parts.

ELLIS. I. A N. county of Texas, drained by Trinity river, which forms its E. boundary; area, 1,000 sq. m.; pop. in 1870, 7,514 of whom 1,506 were colored. The surface is occupied by prairies and tracts of hard timber. The prairies are very fertile. The chief productions in 1870 were 11,943 bushels of wheat, 312,843 of Indian corn, 16,076 of oats, and 2,960 bales of cotton. There were 7,387 horses, 3,892 milch cows, 21,211 other cattle, 3,007 sheep, and 8,171 swine. Capital, Waxahachie. **II.** A W. central county of Kansas, intersected by Smoky Hill and Saline rivers and Big creek; area, 900 sq. m.; pop. in 1870, 1,336. The Kansas Pacific railroad passes through it. Capital, Rome.

ELLIS, George, an English author, born in 1745, died in April, 1815. He commenced his literary career as a writer of political satires, and became favorably known as a contributor to the "Rolliad," and subsequently to the "Anti-Jacobin." The study of early English literature, however, occupied his leisure hours, and in 1790 he produced "Specimens of Ancient English Poetry," of which enlarged editions appeared in 1801 and 1811. A companion work, "Specimens of Ancient English Romances," appeared in 1805 (3 vols. 8vo), and has been republished in Bohn's "Antiquarian Library" (London, 1848).

ELLIS, George Edward, D. D., an American clergyman, born in Boston, Aug. 8, 1814. He graduated at Harvard college in 1833, studied theology at the Cambridge divinity school till 1836, and after a year's travel in Europe was ordained in 1840 as pastor of the Harvard church, Charlestown, Mass., and resigned Feb. 22, 1869. From 1857 to 1864 he was professor of doctrinal theology in the Cambridge divinity school. In 1864 he delivered a course of Lowell lectures on the evidences of Christianity. He wrote the lives of John Mason, Anne Hutchinson, and William Penn, in Sparks's "American Biography," and in 1857 pub-

lished a very elaborate work, "The Half Century of the Unitarian Controversy." He edited for a time the "Christian Register," the religious newspaper of the Massachusetts Unitarians; and for some years, in connection with the Rev. Dr. George Putnam, he conducted the "Christian Examiner." He has published many sermons and addresses, and has contributed largely to various periodicals, most frequently upon topics of American history. He is also the author of "The Aims and Purposes of the Founders of Massachusetts" (1869), "Memoir of Jared Sparks" (1869), and "Memoirs of Sir Benjamin Thompson, Count Rumford" (1871).

ELLIS, George James Welbore Agar, Lord Dover, an English author, born Jan. 14, 1797, died July 10, 1833. He was the son of Henry Welbore, afterward Viscount Clifden; was educated at Christchurch, Oxford; represented various constituencies in the house of commons, and was raised to the peerage as Baron Dover in 1831. He was a munificent patron of the fine arts, and in 1832 was president of the royal society of literature. He wrote "The true History of the Man in the Iron Mask," "Historical Inquiries respecting the Character of Edward Hyde, Lord Clarendon," and a "Life of Frederick the Great." He also edited the "Ellis Correspondence," and "Horace Walpole's Letters to Sir Horace Mann."

ELLIS, Sir Henry, an English author and antiquary, born in London, Nov. 29, 1777, died Jan. 15, 1869. He graduated at St. John's college, Oxford, in 1799, in 1805 became one of the assistant librarians of the British museum, and was head librarian from 1827 to 1856. A new and enlarged edition of Brand's "Popular Antiquities" was issued under his care in 1813, and was republished in a cheaper form in 1842. In 1816 he wrote a careful and elaborate introduction to the "Domesday Book," and in 1824 published a series of "Original Letters illustrative of English History," from autographs in the British museum, in 3 vols. 8vo; a second series, in 4 vols., in 1827; and a third, in 4 vols., in 1846. He was also the author of works on the Towneley and on the Elgin and Phigalean marbles (each 2 vols. 8vo, 1833 and 1836), and compiled and edited several valuable volumes for the society of antiquaries and for the Camden society. He received the Hanoverian Guelphic order of knighthood in 1833.

ELLIS. I. William, an English missionary and author, born in London in 1794, died there, June 9, 1872. In 1815 he became connected with the London missionary society, under whose auspices, in January, 1816, he sailed for Polynesia. He spent eight years in promoting the spiritual welfare of the natives of the South sea islands (at one of which, Tahiti, he erected the first printing press in Polynesia), and in 1824 returned to England on account of the illness of his wife, stopping for some time on the way in the United States. For some years he

was employed in the business of the London missionary society at home, and published "Narrative of a Tour through Hawaii" (London, 1826); "Polynesian Researches" (2 vols. 8vo, 1828); "History of Madagascar," compiled from information received from missionaries and government documents (2 vols., 1838); "History of the London Missionary Society" (1844); "Village Lectures on Popery" (1851), &c. In 1835 his wife died, and two years later he was married to Sarah Stickney, with whom he resided many years in Hoddesdon, Hertfordshire, where Mrs. Ellis conducted a school for girls. In 1853 he went to Madagascar on a mission of observation for the London missionary society, and, after two other visits to that island published "Three Visits to Madagascar, during 1853-'6, with Notices of the People, Natural History, &c." (London, 1858). A memoir of Mr. Ellis by his son was published in 1873.

II. Sarah Stickney, an English authoress, wife of the preceding, born in London in 1812, died there, June 16, 1872. Her parents belonged to the society of Friends. Her first literary production was a didactic work for the young, entitled "The Poetry of Life." She subsequently wrote many volumes devoted to the moral and mental culture of her sex. The principal of these are: "Home, or the Iron Rule;" a series entitled "The Women of England" (1838), "The Daughters of England" (1842), "The Wives of England" (1843), and "The Mothers of England" (1843); "Look to the End" (2 vols., 1845); "Hearts and Homes" (3 vols., 1848-'9); "Mothers of Great Men" (1860); "The Brewer's Family" (1863); "Education of the Heart" (1869); and "The Melvill Family" (1871).

ELLIS, William, an English writer on social science, born in London in 1800. In 1846 he procured the introduction of social science as a branch of elementary education in the London schools, and is the author of "Progressive Lessons in Social Science," "The Phenomena of Industrial Life," "Education as a Means of preventing Destitution," &c. He has written several articles on these subjects for periodicals.

ELLISTON, Robert William, an English actor, born in London, April 7, 1774, died there, July 7, 1831. He was educated at St. Paul's school, but at the age of 17 ran away and joined a theatrical company at Bath, where he made his first appearance on the stage April 21, 1791. Five years later he made his debut in London, at the Haymarket theatre, and in 1803 became principal actor and acting manager of that house. In the succeeding year he was engaged at Drury Lane, but after the burning of the theatre, having quarrelled with Thomas Sheridan, he left the company, and opened the Surrey theatre. On the rebuilding of Drury Lane he was again engaged as a leading actor, and recited the address written by Lord Byron for the opening night. In 1819 he became the lessee of Drury Lane, but in 1826 retired a bankrupt. Subsequently he was

again manager of the Surrey theatre, and continued occasionally to perform his principal characters until the close of his life. He was called the first comedian of his time. His chief merit perhaps was the facility with which he adapted himself to every variety of characters, from the humorous to the tragic. He possessed inordinate self-esteem, and many anecdotes are told of his eccentricities.

ELLORA, *Elora*, or *Elouro*, a decayed town of Hindostan, in the Nizam's dominions, 13 m. N. W. of Aurungabad, celebrated for its cave temples, excavated from the inner slope of a crescent-shaped hill of red granite and black and gray basalt, about a mile from the town. These caverns are sculptured over an extent $1\frac{1}{2}$ m. in length, and may be regarded as a Hindoo pantheon, since every divinity of India has there a shrine. Most of the caves are not less than 100 ft. in depth; 20 of them are conse-

designs and sculptures representing lions, tigers, elephants, and fantastic animals of all sorts. Within are 42 colossal figures of Hindoo divinities, each one the centre of a group; and beyond this main temple may be seen others of smaller size and similar decorations. These gigantic works, which Elphinstone and others compare with the pyramids of Egypt as works of labor, and far surpassing them as specimens of art, are of unknown antiquity, and seem to have been executed by Buddhists as well as by Brahmans. The village of Ellora is small, and is resorted to by numerous pilgrims.

ELLSWORTH, a central county of Kansas, intersected by Smoky Hill river; area, 720 sq. m.; pop. in 1870, 1,185. The Kansas Pacific railroad passes through it. The chief productions in 1870 were 2,175 bushels of wheat, 12,167 of Indian corn, 4,393 of potatoes, and 1,604 tons of hay. Capital, Ellsworth.

Temple of Kailasa.

crated to Siva, and two to the Trimurti, or Brahmanic trinity. They are all adorned with colossal statues and innumerable sculptures and bass-reliefs. The greatest and most remarkable of these monuments is the *Kailasa*, or paradise, dedicated to Siva, and designed to represent the court of that divinity where he receives those of his worshippers who, having escaped metempsychosis, come after death to enjoy eternal happiness. This does not, like the others, extend subterraneously, but rises to a lofty height in an excavation 401 ft. in depth and 185 in breadth. It is composed of a portico, a chapel, and a grand pagoda. The portico is sustained by pillars and flanked by curious sculptures. Two obelisks, 41 ft. in height, 11 ft. square, beautifully carved, and two gigantic elephants, surround and support the chapel, which is likewise adorned on every side by statuary. The pagoda rises from the centre of the whole structure to the height of 100 ft., and is surrounded externally by mythological

736; engaged in the cod and mackerel fishery, 50 vessels of 1,543 tons. The city contains 11 manufactories of lumber, 2 of planing machines, pails, sash, blinds, &c., 1 of pumps, blocks, &c., 4 of saddles and harness, 2 of carriages and sleighs, 1 of axes, 1 of furniture, 2 of sails, and an iron and brass foundry. There are 4 hotels, a weekly newspaper, a library of 1,000 volumes, 22 school houses with an average of about 800 pupils, and 6 churches.

ELLSWORTH. I. Oliver, an American statesman and jurist, born in Windsor, Conn., April 29, 1745, died Nov. 26, 1807. He graduated at the college of New Jersey in 1766, and soon after commenced the practice of law. In 1777 he was chosen a delegate to the continental congress, and he was a member of the council of Connecticut from 1780 to 1784, when he was appointed a judge of the superior court. In 1787 he was elected to the convention which framed the federal constitution, and was afterward a member of the state convention

which ratified that instrument. He was a senator of the United States from 1789 to 1796, when he was nominated by Washington chief justice of the supreme court of the United States, over which he presided with great distinction, his opinions being marked by sound legal and ethical principles, in clear and felicitous language. In 1799 he was appointed by President Adams envoy extraordinary to Paris, and with his associates, Davie and Murray, he successfully negotiated a treaty with the French. This accomplished, and his health beginning to fail, he visited England for the benefit of its mineral waters; but his infirmities increasing, he resigned his office of chief justice in 1800. Returning to Connecticut, he was again elected a member of the council; and in 1807 he was appointed chief justice of the state, which office he declined on account of his health. **II. William Wolcott**, son of the preceding, born in Windsor, Nov. 10, 1791, died in Hartford, Jan. 15, 1868. He graduated at Yale college in 1810, and was admitted to the bar in 1813. From 1829 to 1833 he was a representative in congress; from 1838 to 1842 governor of Connecticut; and from 1847 to 1861 judge of the supreme court of that state.

ELLWANGEN, a town of Württemberg, situated on the Jaxt, 55 m. N. E. of Stuttgart; pop. in 1867, 3,895, of whom about 700 are Protestants. It is the seat of the government of the circle of Jaxt, and has several schools and charitable institutions. The manufactures were formerly insignificant, but are growing in importance. Until 1802 it was the capital of the sovereign Benedictine provost of Ellwangen, who had a territory of about 140 sq. m. and an income of 120,000 florins. Near the town are the castle of Hohen-Ellwangen and a famous pilgrims' church.

ELLWOOD, Thomas, an English Quaker minister, a friend of Milton, born in Crowell, Oxfordshire, in 1639, died March 1, 1713. At an early age he attached himself to the society of Friends, thereby giving great offence to his father; but neither blows nor persuasions could induce him to renounce his new sentiments, to take off his hat before his parents, or to address them with other pronouns than "thou" and "thee." He was the author of numerous controversial works, the most considerable of which is his "Sacred History of the Old and New Testaments" (1705-'9). He wrote a poem entitled "Davideis" (1712), of which King David was the hero, and also left "Memoirs of his own Life" (1714). But he is chiefly known from the circumstance that he was one of those selected by the poet Milton to read to him after the loss of his sight. During the raging of the plague in London in 1665 he obtained a retreat for Milton at Chalfont, and there he is said first to have suggested the idea of the "Paradise Regained."

ELM, a tree of the natural order *ulmaceæ*, which embraces some of the noblest and most important species in the United States. All

the plants belonging to this family have simple, rough, serrate, unequal-sided leaves; flowers small, in bunches on the side of the twigs; the fruit either a winged samara or a drupe. Three genera of *ulmaceæ* are found within the limits of the United States. The most conspicuous of these is *ulmus*, of which we especially notice the white or American elm (*U. Americana*, Linn.). No tree can surpass this in the beauty of its proportions. In old trees especially, from the wide-spreading, buttress-like roots to the wider spreading branches, the curvature is beautiful and graceful in the extreme. Situation seems, however, to give variety to the outline. In wet pastures or similar moist places, it sends up a tall, slender trunk, crowned with a few pendent limbs, and clothed nearly from the ground with a feathery investment of small branches, which are scarcely more than leafy bunches of twigs, and presents a most graceful and striking appearance. The rapidity of its growth adapts it to arti-

American Elm (*Ulmus Americana*).

ficial planting where shade is soon needed. Hardy to an unusual degree, it is a great favorite with the tree planter, and is found from Hudson bay to Georgia. The wood of the white elm is used for making hubs of wheels, and is preferred for that purpose to any other native wood. Yokes are made of it, and near the coast ship blocks are constructed of its timber. The white elm grows readily from seed, which should be sown as soon as ripe, and may be gathered in almost any desirable quantity from the ground under the trees, falling as early as June. The seeds should be very slightly covered, and the young plants will rise in a few weeks, when they should be watched and weeded, and in succeeding seasons should be thinned out and transplanted to insure well formed trees. In transplanting large and vigorous young specimens found where they have appeared spontaneously, it is necessary to secure as many of the fibrous

roots as possible, and have them spread out in large and ample holes, well prepared with good soil; care must be taken not to have them too deeply covered. The slippery or red elm (*U. fulva*, Mx.) is a much smaller tree, with larger and more beautiful foliage, and

Slippery Elm (*Ulmus fulva*).

soft, downy, rusty-haired buds, whence the name sometimes applied of red elm. Its flowers are in lateral clusters; the samara is larger and with a broader border. The inner bark contains a great quantity of mucilage, of much value in medicine. Michaux considers its wood as superior to that of the white elm. The tree can be readily grafted upon the white

American Elm (*Ulmus Americana*).

elm, and if only for ornament it is well worthy of cultivation. The corky white elm (*U. racemosa*, Thomas) has its branches often beset with corky ridges; its leaves are similar to those of the white elm; its flowers are in racemes; its wood is tougher and finer grained.

The wahoo or winged elm (*U. alata*, Mx.) is a small tree, seldom exceeding 30 feet in height, has a fine-grained, valuable wood, and is to be found in Virginia and southward. The English elm (*U. campestris*, Linn.) was early introduced into this country, and is a

English Elm (*Ulmus campestris*).

stately tree, contrasting finely with the American. Its branches, unlike that, tend upward, or else spread more horizontally, and its foliage is of a darker green and more pleasing to the eye. The wych elm (*U. montana*, Bauhin) has been partially introduced; it is much cultivated in Scotland, and goes by the name of the Scotch elm. It resembles the slippery

Wych Elm (*Ulmus montana*).

elm.—The nettle tree (*Celtis occidentalis*, Linn.) has a trunk from 20 to 60 ft. high. Its leaves are obliquely lanceolate, acuminate, sharply serrate; its fruit is a sort of plum or drupe of a yellowish green color. It has several varieties, considered by some botanists as distinct species, but probably nothing more

than forms of the above. They grow on the poorest and most arid soils, but flourish best in a rich and moist ground. Michaux says that the wood of the hackberry (*C. crassifolia*, Mx.) is fine-grained and compact, but not heavy. The planer tree (*planera aquatica*, Gmelin) has small leaves like those of elms; the flowers are borne in small axillary clusters; the fruit is nut-like. According to Michaux, it grows on wet banks in Kentucky and southward. He considers its wood as hard, strong, and proper for various purposes. It has not, however, been put to any use in this country, and is so little esteemed as to have received no popular name. It is worthy of attempts at cultivation northward, and can be readily propagated by grafting it upon the elm.

ELMACINUS, *Elmacin*, or *Almakin*, **George** (known in the East by the name of Ibn Amid), an Arabian historian, born in Egypt in 1223, died in Damascus in 1273. He was a Christian, and held at the court of the sultans of Cairo the office of *ketib* or secretary. He wrote a history of the East, especially of the Arabs, from the creation of the world to the time of the crusades, a portion of which was published both in Arabic and Latin by Erpenius, at Leyden, in 1625; the Latin version was soon reprinted, and was followed by a French translation. A complete edition in Arabic remains in use among the Christians of the Levant.

ELMES, **James**, an English architect, born in London, Oct. 15, 1782, died in 1862. He gained the silver medal in architecture at the royal academy in 1804, and was for some time surveyor and civil engineer of the port of London; but loss of sight (which, however, he afterward partially recovered) caused him to relinquish the office in 1828. He published "Sir Christopher Wren and his Times" (4to, 1823); "Lectures on Architecture" (8vo, 1823); "General and Bibliographical Dictionary of the Fine Arts" (8vo, 1826); "On the Law of Dilapidations" (royal 8vo, 1826); "Treatise on Architectural Jurisprudence" (8vo, 1827); "Survey of the Harbor and Port of London" (1838); "Horæ Vacivæ" (1851); and "Thomas Clarkson, a Monograph" (1854).

ELMINA, or **St. George da Mina**, a British settlement on the Gold coast, Ashantee, Africa, at the mouth of the river Beyah, about 6 m. W. of Cape Coast Castle; lat. 5° 5' N., lon. 1° 20' W.; pop. about 15,000. The native town is large, irregular, and very dirty. The inhabitants are chiefly fishermen, traders and their servants, and slaves employed as mechanics; but there are a few mulattoes who are wealthy. In the neighborhood are some handsome country residences and cultivated farms. The surrounding country is undulating and thickly wooded. The town is defended by a castle built on a low rocky peninsula extending from the E. bank of the river. The point is surrounded by a bed of rocks, on which the sea breaks with great violence. The castle, the oldest European settlement on the Guinea coast, was begun by the

Portuguese about 1481, and was 80 years in building; it is secure against an attack from any native force. There is another large defensive work, the fort of St. Jago, which commands the castle; but its climate is reputed to be fatal to Europeans.—Elmina was captured by the Dutch in 1637, and was ceded to them by Portugal in 1641. In 1872 it was transferred together with the other Dutch settlements on the coast to Great Britain. This transfer resulted in a war with the Ashantees in 1873; and on June 13 the native king's quarter of Elmina was bombarded and burned by the British, because the inhabitants had supplied the Ashantees with munitions of war.

ELMIRA, a city and the capital of Chemung co., New York, situated on both sides of the Chemung river, near the mouth of Newtown creek, about 160 m. W. S. W. of Albany, and 175 m. W. N. W. of New York; pop. in 1870, 15,863, of whom 3,391 were foreigners. It is handsomely laid out, in a broad and fertile valley. The Chemung canal connects it with Seneca lake, the Junction canal with central Pennsylvania, and the Erie and Northern Central railroads with New York, Philadelphia, &c. Newtown creek furnishes abundant water power. There are rolling mills and other iron works, flour mills, breweries, tanneries, and manufactories of boots and shoes, edge tools, agricultural implements, carriages, &c. The Elmira iron and steel works manufacture large quantities of rails, besides about 16,000 tons of locomotive and bridge iron annually. The railroad companies have extensive car shops here. There are four banks, a savings institution, 300 stores, a large number of warehouses, and several hotels. The city is governed by a mayor and a board of 12 aldermen, two from each ward. The fire department is under the charge of a chief engineer and two assistants. There are 31 public schools, including a high and a normal school, which in 1872 had 56 teachers and an average attendance of 2,295 pupils; total expenditure for school purposes, \$64,348, of which \$31,037 were for teachers' wages. The Elmira female college (Presbyterian), organized in 1855, had in 1872 12 professors and instructors, 123 students, a library of 3,000 volumes, and an endowment of \$100,000. The Elmira free academy had 5 instructors and 128 pupils. There are two daily and two weekly newspapers, a quarterly periodical, a young men's Christian association, and 20 churches.—Elmira was settled about 1790. It was incorporated as a village under the name of Newtown in 1815, and received its present name in 1828. In 1864 a city charter was granted. Its use by the government during the civil war as a rendezvous for Union troops and as a depot for confederate prisoners materially aided its prosperity.

ELMORE, a S. E. county of Alabama, bounded E. and S. by the Tallapoosa river and intersected by the Coosa; area, about 550 sq. m.;

pop. in 1870, 14,477, of whom 6,730 were colored. The South and North Alabama railroad passes through the S. W. part. The surface is undulating and the soil fertile. The chief productions in 1870 were 10,330 bushels of wheat, 198,371 of Indian corn, 18,078 of oats, 32,560 of sweet potatoes, 5,697 of peas and beans, and 7,295 bales of cotton. There were 944 horses, 1,411 mules and asses, 2,706 milch cows, 3,812 other cattle, and 8,286 swine; 9 manufactories of carriages and wagons, 1 of cotton goods, and 2 saw mills. Capital, Wetumpka.

ELMSLEY, Peter, an English scholar, born in 1773, died March 8, 1825. He was educated at Westminster school, and at Merton college, Oxford. He officiated for a time in a small chapelry in Little Horkesley, Essex; but becoming master of a fortune by the death of an uncle, he devoted himself to literary studies, and particularly to Greek literature. He lived for a while in Edinburgh, where he was intimately associated with the founders of the "Edinburgh Review," and contributed to that periodical several articles, among which were reviews of Heyne's "Homer," Schweighäuser's "Athenæus," Blomfield's "Prometheus," and Porson's "Heceuba." In 1816 he made a voyage to Italy in search of manuscripts, and passed the winter of 1818 in researches in the Laurentian library at Florence. The next year he was appointed to assist Sir Humphry Davy in trying to decipher some of the papyri found at Heracleum. After his return to England he became principal of St. Alban's hall, Oxford, and Camden professor of modern history in the university. From 1809 to 1823 he published editions of several of the Greek tragedies.

ELOCUTION. See ORATORY, and VOICE.

ELOHIM, one of the Hebrew names of the Deity, the plural of *Eloah*. The name is also applied to angels, princes, judges, great men, and even to false gods.

EL PASO. **I.** The extreme W. county of Texas, bounded N. by New Mexico, touched on the N. E. by the Rio Pecos, and separated on the S. W. from Mexico by the Rio Grande; area, 9,450 sq. m.; pop. in 1870, 3,671, of whom 306 were colored. More than nine tenths of the area consists of sandy plains without timber or water. Salt lakes are found in the N. part. It is crossed by several mountain ranges. The only cultivated portion is the narrow valley of the Rio Grande, which is productive when irrigated. Capital, Franklin.

II. A central county of Colorado, bordering on the Rocky mountains, and containing Pike's peak; area, about 2,500 sq. m.; pop. in 1870, 987. The surface is diversified. It is traversed by the Fontaine qui Bout, the valley of which is fertile. The chief productions in 1870 were 11,455 bushels of Indian corn, 11,727 of oats, 8,876 of wheat, 760 tons of hay, and 16,900 lbs. of wool. There were 10,800 sheep; 2 flour mills, and 4 saw mills. Capital, Colorado City.

EL PASO, or El Paso del Norte, an inland town of Mexico, in the N. E. angle of the state of

Chihuahua, on the Rio Grande, near the frontier of New Mexico, 945 m. N. W. of the city of Mexico; lat. 31° 45' N., lon. 106° 28' W.; pop. about 6,000, chiefly mestizoes, with many Indians of pure blood. This place was first established as a military post to check the inroads of the savage tribes which then, as now, ravaged the whole north of the republic. It forms a separate town, though the name is often extended to a series of minor settlements reaching some 15 m. along the banks of the Rio Grande. The fort has been transferred to El Paso del Rio Grande, on the road from Chihuahua to Santa Fé. The country surrounding El Paso consists of well cultivated fields of maize, wheat, and other cereals, dotted with gardens and orchards yielding a luxuriant supply of all the delicate fruits of the temperate zone. The best wine in the republic is made here; and also a species of brandy, called by the border Americans Paso whiskey. The inhabitants, though generally rich, pay little attention to material comfort.

ELPHINSTON, James, a Scottish grammarian, born in Edinburgh in 1721, died at Hammer-smith, near London, Oct. 8, 1809. He studied at the university of Edinburgh, became tutor to Lord Blantyre, superintended an edition of the "Rambler" in his native town, and in 1751 opened a school at Kensington. He was a zealous advocate of a change in English orthography, and published several works on the subject which exposed him to great ridicule. A translation of Martial (4to, 1782) was no better received. His principal works are: "French and English Languages" (2 vols. 12mo, 1756); "Education, a Poem" (1763); "English Language" (2 vols. 12mo, 1765); "Propriety ascertained in her Picture" (1786); *Poete Sententiosi, Latini*, &c. (1794); and "Fifty Years' Correspondence, English, French, and Latin, in Prose and Verse, between Geniusses or both Sexes and James Elphinston" (8 vols. 12mo, 1794).

ELPHINSTONE, George. See KEITH.

ELPHINSTONE, Mountstuart, an English statesman and historian, 4th son of John, 11th Baron Elphinstone, born in 1779, died Nov. 20, 1859. In 1795 he entered the service of the East India company; in 1808 was ambassador to the Afghan court at Cabool; from 1810 to 1817 was resident at the court of Poona, and was commissioner to that province from 1817 to 1819, when he was appointed governor of Bombay. He resigned in November, 1827. He was the author of an "Account of the Kingdom of Cabul and its Dependencies in Persia, Tartary, and India" (4to, London, 1815), which has been twice reprinted; and "History of India: the Hindoo and Mahometan Periods" (2 vols. 8vo, 1841; 3d ed., 1848).

ELSNORE, or *Elsineur* (Dan. *Helsingör*), a maritime town of Denmark, in the bailiwick of Frederiksborg, island of Seeland, 23 m. N. E. of Copenhagen; lat. 56° 2' N., lon. 12° 38' E.; pop. in 1870, 8,891. It is built on

the narrowest part of the Sound, here but $3\frac{1}{2}$ m. in width, opposite the Swedish town of Helsingborg. It commands the principal passage between the Cattegat and the Baltic, and is the spot where the Sound dues (abolished in 1857) were formerly paid by all foreign vessels, except those of Sweden, navigating that channel. The town is substantially but irregularly built on ground rising gradually from the shore. The harbor is very small, but has a depth of 18 ft. The roadstead is excellent, and is generally crowded with vessels, and there is a large foreign commerce. Adjacent to the harbor, on the N. E., on a tongue of land running out into the sea, is the castle of Kronborg, built by Frederick II. about 1580. Modern fortifications have since added to its strength. It is now chiefly used as a prison. Caroline Matilda, queen of Christian VII., was imprisoned here until the interference of her brother, George III. of England. Under the

the Swedes, under the orders of Wrangel, but was restored to the Danes in 1660. It failed to prevent the passage of the British fleet under Sir Hyde Parker, with Nelson as his second in command, in 1802.

ELSSLER, Fanny and Therese, two sisters celebrated as dancers, born in Vienna, Therese in 1808, Fanny in 1811. Fanny, the more famous, was instructed in the juvenile ballet corps of the Viennese theatre, and at the age of six made her appearance on the stage. Subsequently she received instructions from Aumer, and a marked influence upon her general æsthetic culture was exercised by Baron Friedrich von Gentz. The two sisters went to Naples in 1827, and in 1830 made their first appearance at Berlin. Subsequently they went to Vienna and other cities, and on Sept. 19, 1834, they made their first appearance in Paris, in *La tempête*, a ballet adapted from Shakespeare's "Tempest" by Adolphe Nourrit. Fanny

ranked with Taglioni, then at the head of her profession in Paris, and she soon eclipsed her celebrated rival in the Spanish *cachucha*. In 1841 the sisters visited the United States, where they met with brilliant success, and afterward went to Russia. In 1851 Fanny retired from the stage with a large fortune, and purchased a villa near Hamburg. Her sister contracted in April, 1850, a morganatic marriage with Prince Adalbert of Prussia (who died in 1873), and was ennobled under the title of Frau von Barnim.

Kronborg Castle.

castle are casemates capable of holding 1,000 men. According to a popular tradition, Holger Danske, the legendary hero of Denmark, resides in one of the subterranean vaults. In the courtyard of the castle is the lighthouse, showing a fixed light 113 ft. above the sea. A short distance N. W. of the town is the palace of Marienlyst (Mary's delight), once a royal residence, but now in private occupation. Near by is shown a pile of rocks, erroneously called the tomb of Hamlet, of whose story, as told by Shakespeare, Elsinore is the scene. Local industry is mostly engaged in the refining of sugar and brandy, printing cottons, fishing, &c.; and there is an extensive manufactory of arms at Hammerwolle in the suburbs. —Elsinore was erected into a city in 1425; was taken and burned by the forces of Lübeck in 1522, and was retaken in 1535 by Christian II. It was enlarged by Dutch colonists in 1576. The castle was taken Sept. 6, 1658, by

ELTON, a salt lake in the government of Astrakan, Russia, 70 m. E. of the Volga, and 130 sq. m. in extent. It yields annually upward of 100,000 tons of salt, the collection of which gives employment to 10,000 persons. In the hottest season the crystallized salt along its banks and on its surface gives it the appearance of a vast sheet of ice or frozen snow. It is nowhere more than 15 inches deep.

ELVAS, a fortified frontier city of Portugal, in the province of Alentejo, 105 m. E. of Lisbon, and 10 m. W. of Badajoz, Spain, on a hill near the bank of the Guadiana; pop. about 10,000. It became a city in 1513, and was created a bishopric by Pius V. in 1570. It is an important stronghold, having an arsenal, and spacious bomb-proof barracks for 7,000 men. The fort of Lippe on a neighboring hill is considered impregnable. The town itself is poorly built, and many of the venerable Moorish buildings which line its streets are crumbling to

pieces. It has a cathedral, college, seminary, theatre, several churches and convents, and manufactories of arms and jewelry. It is supplied with water from a distance of three miles, by means of a fine Moorish aqueduct. During the peninsular war it was a place of great importance; and in March, 1808, it was taken by the French under Junot, and held till the convention of Cintra in August, 1808.

ELWES, John, an English miser, born in Southwark about 1714, died Nov. 26, 1789. His own family name was Meggot, but he exchanged it for that of his uncle, Sir Harvey Elwes, from whom he received a large inheritance. At an early period of his life he attended Westminster school, and became a good classical scholar. He was sent to Geneva to complete his education, and there distinguished himself as one of the boldest riders in Europe. After returning to England he indulged in

gambling, frequenting the most noted gaming houses. He next took to hunting, and his stable of fox hounds was considered the best in the kingdom; yet he kept but a single servant to attend to all his cows, dogs, and horses. From his parsimonious mode of life his fortune rapidly increased, and when worth half a million he refused to accept a seat in parliament unless on the express stipulation that he should be brought in for nothing, and was elected for Berkshire in 1774. His miserly habits increased with his fortune, and during the latter years of his life he abandoned gaming, hunting, and every comfort, and died the possessor of £800,000, after having suffered greatly from fear of poverty.

ELY, a city of Cambridgeshire, England, on an eminence near the Ouse, 16 m. N. N. E. of Cambridge; pop. about 8,000. It consists principally of one street, and contains many old

Ely Cathedral.

buildings. It is the seat of a bishopric which was founded in 1107. Its cathedral is a splendid structure, built in successive centuries from 1174 to 1534, and presenting a singular mixture of the Saxon, Norman, and early English styles. The churches of St. Mary and of the Holy Trinity are also remarkable both for their age and splendor. A famous convent was founded here about 670 by Ethelreda, wife of Egfrid, king of Northumberland, and she became its first abbess. It was destroyed by the Danes in 870, and 100 years later was rebuilt by Ethelwold, bishop of Winchester, who placed in it monks instead of nuns. Ely has manufactures of earthenware and tobacco pipes, breweries, flax and hemp-seed oil mills, lime kilns, extensive gardens in its vicinity, the produce of which is sent to the London and Cambridge

markets, and several benevolent institutions and schools, among which is a grammar school founded by Henry VIII. It is the capital of a division of Cambridgeshire called the "Isle of Ely," separated from the rest of the county by the Ouse. This district is included in the reclaimed marsh known as Bedford Level.

ELYMAIS, a province of ancient Elam, between the river Eulæus and the Persian gulf. The notices of it in classical writers are very confused; but it was more probably a district of Elam than an independent territory S. of it, or merely a town. The books of Maccabees and Tobias name it as a city of Persia, to which Antiochus Epiphanes laid siege; but not one of the ancient writers who speak of this expedition mentions the place. Elymais is often used as equivalent to Elam. (See **ELAM**.)

ELYSIUM, or **Elysian Fields**, among the Greeks and Romans, the dwelling place of the blessed after death. While the oriental and most other peoples sought this abode in the upper regions of the sky, the Greeks placed it in the west, on the ends of or beneath the earth, where the sun goes down. According to Homer, Elysium was a plain on the ends of the earth, where men live without toil or care, where there is neither snow nor winter storms nor rains; where the lovely and cooling zephyrs blow unceasingly with light murmur; and where dwelt Rhadamanthus, who, in the upper world, was the justest of men. The position of Elysium changed with the progress in geographical knowledge, proceeding further and further to the west. Hesiod speaks of the happy isles of the ocean, and other writers supposed it to be somewhere in the Atlantic, till Pindar and the later poets put it beneath the earth. According to the later description, the meads of Elysium three times in a year brought forth the most beautiful flowers. The inhabitants enjoyed the reward for their virtues on earth, and whoever had three times resisted a temptation to do evil attained to this abode. A never-setting sun shone upon them, and melancholy was removed far away. The air, fragrant and tinted with purple, breathed softly from the sea, the flowers were twined into wreaths for the dwellers, peaceful waveless rivers flowed by, and horse races, games, music, and conversation occupied the hours. According to Homer, Rhadamanthus alone ruled Elysium, being admitted there as the representative of justice. Hesiod knows Elysium as the Isles of the Blessed, where Cronos rules, and Titans and heroes dwell.

ELZEVIR, **Elsevier**, or **Elzevier**, the name of a family of Dutch printers, established at Leyden, Amsterdam, the Hague, and Utrecht, in the 16th and 17th centuries, and who for nearly 100 consecutive years were distinguished for the number and elegance of their publications, especially their editions of ancient authors.—Louis, the founder of the family, born in Louvain in 1540, emigrated to Holland in 1580, in consequence of the religious troubles which agitated his native city, and settled in Leyden, where he died, Feb. 4, 1617. He became a petty officer of the university of Leyden, and also engaged in the business of a bookseller and printer. In the latter capacity he is said to have produced, between 1583 (when the *Drusii Ebraicarum Questionum ac Responsionum libri duo*, the first book bearing the imprint of Elzevir, appeared) and his death, 150 works. He is said to have been the first printer who observed the distinction between the vowels *i* and *u* and the corresponding consonants *j* and *v*. Of the seven sons of Louis, five followed the business of their father, viz.: MATTHEUS, who was established at Leyden, where upon his death in 1640 he was succeeded by his sons Abraham and Bonaventure, who became partners in Leyden; Louis (II.), who

in 1590 established a printing house at the Hague, and died there in 1621; GILLES, who was in business at the Hague and subsequently in Leyden; Joost, who settled in Utrecht; and BONAVENTURE, who was born in 1583 and died about 1652. Bonaventure in 1626 associated himself with ABRAHAM, the son of Mattheus, and from their press issued those numerous exquisite editions of the classics, as also those on history and politics (62 vols. 16mo), called by the French *Les petites républiques*, with which the name of Elzevir is now most familiarly associated. The Livy and Tacitus of 1634, the Pliny of 1635, the Virgil of 1636, and the Cicero of 1642, are among the best of their productions. Abraham died Aug. 14, 1652. Their children carried on the business for some time under the name of their parents. LOUIS (III.), son of Louis (II.), founded the Elzevir printing establishment at Amsterdam in 1638, and entered into a partnership with his cousin Daniel in 1654, which lasted 10 years. He was born in 1617, and died in 1670, at which time the reputation of the Elzevirs had reached its highest point. Among their chief publications are the celebrated New Testament of 1633, a series of Latin classics, the *Etymologicon Lingue Latine*, and an edition of the *Corpus Juris*. Between 1664 and 1680 Daniel carried on the business alone, and in that period published 152 works. He was the last of his family who excelled in printing, although his widow and Pieter, grandson of Joost, carried on the business for some years.—The merit of the Elzevirs consisted less in their learning or critical abilities, in which they were inferior to the Aldi, the Stephenses, and others of the celebrated printers of the 15th, 16th, and 17th centuries, than in the clearness and beauty of their type, the excellent quality of their paper, which was made in Angoulême, and the general elegance of their publications. The texts of their editions of the classics were generally reprints, and were sometimes pirated from other sources. All their choice works, particularly the small editions of the classics, bring large prices at the present day; and the name Elzevir applied to a book has become a synonyme for typographical correctness and elegance. The Elzevirs printed several catalogues of their works, but the best account of them is to be found in the *Notice de la collection d'auteurs latins, français et italiens, imprimée de format petit en 12mo par les Elzevir*, in Brunet's *Manuel du libraire* (Paris, 1820), and in Bérard's *Essai bibliographique sur les éditions des Elzevirs* (Paris, 1822). See also Pieter's *Annales de l'imprimerie elzévirienne* (Ghent, 1851-'2), in which the number of works printed by the Elzevirs is stated at 1,213, of which 968 were in Latin, 44 in Greek, 126 in French, 32 in Flemish, 22 in oriental languages, 11 in German, and 10 in Italian. Their imprint was: *Apud Elzevirios, or Ex Officina Elzeviriorum or Elzeviriana*; and frequently the title page of their books contains a device of a blazing wood

pile, emblematic of their name, compounded of *els*, alder, and *vuur*, fire.

EMANUEL, an E. county of Georgia, bounded N. by the Ogeechee river, and S. W. by Pendleton's creek; area, about 1,000 sq. m.; pop. in 1870, 6,134, of whom 1,703 were colored. The principal streams which intersect it are the Great Ohoopee and the Cannouchee. It has a level surface, and a sandy, unproductive soil. Timber is abundant. The chief productions in 1870 were 103,705 bushels of Indian corn, 21,399 of oats, 24,353 of sweet potatoes, and 1,376 bales of cotton. There were 1,094 horses, 4,013 milch cows, 11,167 other cattle, 14,988 sheep, and 15,464 swine; 4 saw mills and 1 cotton factory. Capital, Swainsborough.

EMANUEL (Port. MANOEL) I., king of Portugal, called the Great, and the Happy, born May 3, 1469, ascended the throne upon the death of John II., in 1495, and died in Lisbon, Dec. 13, 1521. He was the son of Duke Ferdinand of Visen, grandson of King Edward of Portugal, nephew of Alfonso V., and cousin of John II. His father, accused of conspiracy against John II., was slain by the latter with his own hand. Emanuel, bearing the title of duke of Beja, was educated in Spain, where in 1497 he married Isabella, daughter of Ferdinand and Isabella, and heiress to the crown of Castile. She died in 1498, and Emanuel married Donna Maria, her sister, two years later. He received the kingdom in a state of prosperity, and by his activity and sagacity raised Portugal to her most brilliant point of power and glory. He signalized the beginning of his reign by pursuing with an ardor surpassing that of all his predecessors the long-sought passage by sea to India. Mainly under his patronage were made the voyages of Vasco da Gama, Albuquerque, and Pedro Alvarez de Cabral; in his reign Goa became a Portuguese settlement, and Brazil, the Moluccas, &c., were discovered; the commerce of the Indies was opened to Portugal, wealth accumulated, and a spirit of enterprise took possession of the nation, which could now boast of a brilliant succession of navigators and generals. Less successful were his efforts for conquest in Morocco, where dearly purchased victories secured no lasting gain. He devoted himself to the Roman Catholic church, sent missionaries with all his fleets to convert whatsoever people they might discover, and sought to reform the character of the Portuguese ecclesiastics. He banished the Jews and Moors, and introduced the inquisition. He ruled 20 years without convening the cortes, published a code of laws, and succeeded in remaining at peace with all Europe. He was a patron of men of letters, and himself the author of memoirs of the Indies. His second wife, Maria, died in 1517, and in 1519 he married Eleonora of Austria, sister of Charles V.

EMBALMING, the process of preserving animal bodies from corruption by introducing antiseptic substances into the spaces left vacant by the

removal of the internal parts. The art was extensively practised by the ancient Egyptians, and the mummies found at this day in their sepulchres, where they have lain for 3,000 years or more, testify to the perfection it had reached in those remote periods. Reptiles and other animals were held sacred and worthy of embalming; therefore when, in addition to the countless bodies of human beings still to be found in the places where they were deposited, are reckoned the millions of dogs, apes, crocodiles, cats, ibises, bulls, rams, foxes, asps, and other animals, of more than 50 species in all, it is a matter of wonder whence were obtained all the resins, drugs, and spices which are described as essential to the process. After Egypt became a Roman province the art continued to be practised, and was adopted to some extent by the Romans themselves. Among other races also the same practice has in former times prevailed, or at least a modification of it designed to produce a similar result; such, for example, as drying the bodies of the dead. This was probably the custom of the Guanches, the former inhabitants of the Canary islands. In the great temple of the sun at Cuzco bodies of the incas and of their queens have been found, clothed in their former princely attire, seated upon chairs of gold, their heads inclined downward, covered with raven-black or silver-gray hair, and their hands placidly crossed over their bosoms. Exposure of the bodies to the exceedingly dry and cold air of the mountainous region, it was thought by Garcilaso, was sufficient to preserve these bodies without recourse to the artificial processes adopted by the Egyptians. These have been particularly described by Herodotus and Diodorus Siculus, and the accounts of the former especially have been regarded by most authorities as presenting an exact exposition of them. Some, however, question the adequacy of the processes thus given to account for the results, and state that modern experimenters fail entirely of success in endeavoring to perform the operation by their instructions. The account given by Herodotus (ii. 86) is as follows: "There are a set of men in Egypt who practise the art of embalming, and make it their proper business. These persons, when a body is brought to them, show the bearers various models of corpses made in wood, and painted so as to resemble nature. The most perfect is said to be after the manner of him [Osiris] whom I do not think it religious to name in connection with such a matter; the second sort is inferior to the first, and less costly; the third is the cheapest of all. All this the embalmers explain, and then ask in which way it is wished that the corpse should be prepared. The bearers tell them, and having concluded their bargain, take their departure, while the embalmers, left to themselves, proceed to their task. The mode of embalming, according to the most perfect process, is the following: They take first a crooked piece of iron and with it draw out the brain through the nostrils, thus

getting rid of a portion, while the skull is cleared of the rest by rinsing with drugs; next they make a cut along the flank with a sharp Ethiopian stone, and take out the whole contents of the abdomen, which they then cleanse, washing it thoroughly with palm wine, and again frequently with an infusion of pounded aromatics. After this they fill the cavity with the purest bruised myrrh, with cassia, and every other sort of spicery except frankincense, and sew up the opening. Then the body is placed in natron for 70 days, and covered entirely over. After the expiration of that space of time, which must not be exceeded, the body is washed, and wrapped round from head to foot with bandages of fine linen cloth, smeared over with gum, which is used generally by the Egyptians in the place of glue, and in this state it is given back to the relatives, who enclose it in a wooden case which they have had made for the purpose, shaped into the figure of a man. Then fastening the case, they place it in a sepulchral chamber, upright against the wall. Such is the most costly way of embalming the dead. If persons wish to avoid expense and choose the second process, the following is the method pursued: Syringes are filled with oil made from the cedar tree, which is then, without any incision or disbowelling, injected into the abdomen. The passage by which it might be likely to return is stopped, and the body laid in natron the prescribed number of days. At the end of the time the cedar oil is allowed to make its escape; and such is its power that it brings with it the whole stomach and intestines in a liquid state. The natron meanwhile has dissolved the flesh, and so nothing is left of the dead body but the skin and the bones. It is returned in this condition to the relatives, without any further trouble being bestowed upon it. The third method of embalming, which is practised in the case of the poorer classes, is to clean out the intestines with a clyster, and let the body lie in natron 70 days, after which it is at once given to those who come to fetch it away." Diodorus, whose account is similar, also says: "First, one who is termed a scribe marks upon the left side of the body, as it lies on the ground, the extent of the incision which is to be made; then another, who is the dissector, cuts open as much of the flesh as the law permits with an Ethiopian stone, and immediately runs away, pursued by those who are present, throwing stones at him amidst bitter execrations, as if to cast upon him all the odium of this necessary act." Sir Gardner Wilkinson, in his "Popular Account of the Ancient Egyptians," says: "The embalmers were probably members of the medical profession, as well as of the class of priests. Joseph is said to have commanded the physicians to embalm his father, and Pliny states that during the process certain examinations took place which enabled them to study the disease of which the deceased had died. They appear to have been made in compliance with an order

from the government, as he says the kings of Egypt had their bodies opened after death to ascertain the nature of their diseases, by which means alone the remedy for phthisical complaints was discovered." Dr. Cormack of London, who has investigated the subject, is of opinion that the essential part of the process was the application of heat to the bodies, which were filled with some form of bitumen. By this means creosote was generated and diffused throughout all tissues of the body, and this method was never divulged, while the other operations may have been practised the better to conceal this as well as to add dignity and mystery to the art. The substances found in mummies are altogether of a resinous nature, and the tissue is impregnated with resinous matter; but this and the wine said to be employed could not preserve the animal substance. All parts, and the linen used for enveloping the body in folds sometimes of 1,000 yards, bear the mark of heat; the bandages are commonly reduced almost to tinder. The object of the gum with which they were smeared may have been to produce creosote by the calcination to which they were subjected. Bitumen also appears to have been employed in a liquid state for filling the cavities of the bodies, though no mention is made of heat being applied to decompose it. The cost of the most expensive method of embalming was a talent of silver.—Thénard's "Chemistry" contains a description of a method employed in recent times by Dr. Chaussier. The body, thoroughly emptied and washed in water, is kept constantly saturated with corrosive sublimate. The salt gradually combines with the flesh, gives it firmness, and renders it imputrescible and incapable of being injured by insects and worms. The author states that he had seen a head thus prepared, which for several years had been exposed to the alternations of sun and rain without having suffered the slightest change. It was very little deformed, and easily recognized, although the flesh had become as hard as wood. A process has been introduced into France by J. N. Gannal of injecting a concentrated solution of sulphate of alumina into the veins of the body, which is employed for anatomical preparations as well as for embalming. Dr. Ure states that a solution of chloride of mercury and wood vinegar is most efficacious for similar uses. He is also of opinion, from the statements of Pliny, that wood vinegar, the antiseptic virtue of which is in the creosote it contains, was the essential means employed by the ancient Egyptians in preparing their mummies, and that the odoriferous resins were of inferior consequence. M. Falconi, in a paper read to the French academy some years ago, stated that after a series of experiments made with different salts, he found that sulphate of zinc, prepared of different degrees of strength, was the best material which he had used. An injection of about a gallon would perfectly well preserve a dead body, as

is proved by the preparations belonging to the anatomical cabinet at Genoa. Bodies so prepared preserve all their flexibility for 40 days. It is only after that period that they begin to dry up, still preserving, however, their natural color. The process employed by Brunetti consists of: 1, washing the circulatory system with water by means of injections; 2, injecting with strong alcohol to remove water; 3, injecting with ether to remove fat; 4, injecting with a strong solution of tannin; 5, submitting the body to a current of warm air, dried by passing over chloride of calcium, a sufficient length of time to abstract all moisture. Removal of viscera and filling cavities with undecomposable and antiseptic material will, of course, render the operation more perfect than when these precautions are not taken. During the late civil war in the United States a process of partial embalming was extensively practised, which, when well performed, often preserved dead bodies for a considerable time. It consisted principally in injecting a strong solution of creosote or of carbolic acid into the veins and arteries, and sometimes removing the contents of the abdominal viscera. A strong solution of alum and sugar of lead was also used, and sometimes chloride or sulphate of zinc. Since then carbolic acid and camphor, dissolved in petroleum and colored with vermilion, have been used, it is said, successfully.

EMBARGO (Sp. *embargar*, to arrest), a public prohibition forbidding ships to sail, which may be issued at the outbreak of a war for the purpose of making lawful prizes of hostile ships in port; or, when an important expedition is contemplated, to detain all private vessels, domestic as well as foreign, to secure secrecy; or an embargo may be laid on ships belonging to subjects or citizens with a view to their use as transports or for other government service. In 1794 the American congress laid an embargo for 60 days upon all vessels in the ports of the republic. This was said by the opponents of the measure to be done to obstruct the supply of provisions to the British forces in the West Indies, then engaged in hostilities against the French republic. The embargo most famous in American history is that intended to countervail Napoleon's Berlin and Milan decrees and the British orders in council. On Dec. 22, 1807, on the recommendation of President Jefferson, a law was enacted by congress prohibiting the departure from the ports of the United States of all but foreign armed vessels with public commissions, or foreign merchant ships in ballast, or with such cargo only as they might have on board when notified of the act. All American vessels engaged in the coasting trade were required to give heavy bonds to land their cargoes in the United States. This embargo was repealed by an act passed Feb. 27, 1809, and taking effect March 15, 1809, except so far as related to France and Great Britain and their dependencies; and in regard to them also it was to take

effect after the conclusion of the next succeeding session of congress. A third embargo, laid April 4, 1812, was superseded by the declaration of war against England, June 18, 1812. A fourth embargo was laid by act of Dec. 19, 1813, and repealed four months afterward, prohibiting all exports whatever, and even stopping the coasting trade; fishermen were required to give bonds not to violate the act.

EMBER DAYS, certain days in each of the four seasons set apart by the church for fasting, prayer, and the conferring of holy orders. They are the Wednesday, Friday, and Saturday immediately following the first Sunday in Lent, the feast of Pentecost, the 14th of September, and the 13th of December. The weeks in which these fasts occur are called ember weeks. The name is probably derived from the Saxon *ymbren*, a circuit, *i. e.*, the circular days. Among the English Catholics the term "quarter tenses" is still applied to these quarterly fasts. The French call them *jeûne des quatre temps*, and the Roman ritual *jejunia quatuor temporum*. Some writers have supposed the name to be taken from the ancient custom of using ashes or embers in connection with fasting. The custom of fasting on these days is traced back as far as the 3d century; and a decree of the council of Piacenza, in 1095, fixed the time for them as now observed.

EMBEZZLEMENT, the wrongful appropriation of the goods of another by a clerk, servant, or other person intrusted therewith; differing in this particular from larceny, where the taking as well as the appropriation is felonious.¹ It was not an indictable offence at common law, and the owner of the property embezzled had no other remedy but a civil action for damages, or in some cases for the recovery of the property itself. Thus if a man hired a horse and fraudulently sold him, if the sale was made in the usual course, *i. e.*, in market overt, and there was nothing to put the purchaser upon his guard, the sale was valid, and the owner could only recover damages against the man who had committed the fraud; though if the horse had been stolen, and afterward sold in market overt, the title did not pass, and the owner could reclaim his property. To remedy this defect, various statutes have been enacted whereby the embezzling of the goods of a master by a servant, or by a clerk or person employed, provided such servant or clerk had the custody of the goods, was made felony; so of a guest in an inn, or a lodger in furnished rooms, carrying off any of the effects which he had possession of for use, it was declared to be larceny. Severe penalties are also enacted against embezzlement by clerks in the post office, or by brokers, bankers, attorneys, &c., of any moneys or valuable securities placed in their hands for safe keeping or any special purpose, or by persons intrusted with public moneys or property, munitions of war, &c.

EMBLEMENTS, a term applied to the growing crops of land, produced annually by the labor

of the cultivator. By the common law, if the estate of a tenant for life or at will is terminated unexpectedly without his volition or default, the emblements belong to such tenant or his representatives; but if terminated by the act of the tenant himself, or if a tenant for years sows crops which do not mature within the life of the lease, the emblements pass with the land to the landlord; for the law does not relieve a man from the consequences of his own voluntary act.

EMBRACERY, an attempt to influence a juror by any unlawful consideration, as by private influence or by bribery. This was a criminal offence at common law, and the punishment has been prescribed by different statutes in England and the United States. The offence consists in the attempt, and it is not necessary that it should be successful.

EMBRUN (anc. *Eburodunum*), a fortified town of Dauphiny, France, in the department of Hautes-Alpes, 19 m. E. by N. of Gap; pop. in 1866, 4,736. It is a dreary-looking town of great antiquity, built upon a rock at whose foot flows the Durance. It contains a cathedral with a fine Romanesque tower, and near the former episcopal palace, which is used as a barrack, rises a quaint tower of ancient masonry known as *la tour brune*. The fortress is of the fourth rank, and is separated by a ditch from the mountain behind it. The principal manufactures are of woollen and linen goods.—The bishops (subsequently archbishops) of Embrun are traced back to the days of Constantine the Great, and were endowed by Conrad II. with princely power over a large part of Dauphiny. A portion of their archives was carried off during the wars of the league, and is now in the public library of Cambridge, England. Embrun was successively sacked by the Vandals, Huns, Saxons, and Moors; in 1573 it was taken by the Protestants, who razed the citadel; and in 1692 it was devastated by the duke of Savoy. Louis XIV. built the château of Mont-Dauphin in the vicinity.

EMBRYOLOGY, the study of the mode of formation and development of the animal foetus. The progress of our knowledge on this subject has been marked by several well defined epochs, corresponding with the successive discoveries of as many different investigators. Though many important facts bearing upon embryology were known to the earlier anatomists and physiologists, they were often misinterpreted, and their true relations consequently mistaken. Aristotle and his followers recognized three different modes of generation as occurring among animals, viz. : oviparous, viviparous, and spontaneous generation. Oviparous generation was that form in which the female parent produced eggs, from which the young were hatched, as in most fishes, reptiles, and birds; viviparous generation was that in which the young were discharged alive and fully formed from the body of the parent, as in quadrupeds and the human species; while spontaneous or

equivocal generation was that in which certain animals of a low order, such as worms, insects, parasites, maggots, &c., were supposed to be produced spontaneously, without parents, from the soil, the water, or decaying animal and vegetable substances. By the progress of investigation, however, the last mode of generation was shown to be much less frequent in its occurrence than Aristotle had supposed. The first advance in this direction was made in the latter part of the 17th century, when Redi, an Italian naturalist, studied with care the generation and metamorphoses of insects, showing that many worms and maggots, instead of being produced without parents, were in reality hatched from eggs laid by perfect insects, and that they afterward became developed by the process of growth into forms similar to their parents. He also in 1684 showed that most parasitic animals were provided with sexual organs, and produced their young in the same manner with other and larger species. Vallisnieri soon afterward (1700) extended the observations of Redi, and applied the same conclusions to other species of insects, and to the parasites inhabiting vegetables. In this way the number of species in which spontaneous generation was regarded as possible or probable gradually diminished, as zoölogical science became more extended and more accurate; until, in 1837, Schultze demonstrated, by his experiments upon the infusoria, that even these microscopic animalcules are never produced in situations where their germs neither existed before nor could gain access from without. Subsequently it was generally acknowledged by physiologists that spontaneous generation was a thing unknown in nature, and that the supposed instances of its occurrence were only cases in which the real process of generation had not been sufficiently investigated. The discussion on this point has again been taken up since 1858, and it has been maintained by Pouchet, Bastian, and others, that spontaneous generation may and does take place in the case of the lowest and most imperfectly known forms of infusoria, such as *vibrio*, *bacterium*, *monas*, and *spirillum*. Their experiments, however, are by no means regarded as conclusive by physiologists in general, a large proportion of whom consider the apparent uncertainty of origin as dependent on our imperfect acquaintance with the natural history and development of these minute forms of infusorial life.—The distinction between oviparous and viviparous animals was supposed by the ancients to indicate a fundamental difference in their mode of generation. In oviparous animals the eggs were known to be produced by the female and fecundated by the male, after which the young were hatched from them by incubation. In the viviparous species the embryo was thought to be produced by a mixture of the male sperm with the fluids of the female generative organs; some thinking that the material for the body of the embryo was supplied by the menstrual

blood, others that it came from a kind of female sperm, or seminal fluid secreted by the female organs. In 1651 Dr. William Harvey, in his book on generation, first announced the fact that there is no essential difference in the mode of generation between oviparous and viviparous animals, but that "all animals whatsoever, even the viviparous, and man himself not excepted, are produced from ova." But though the truth of this opinion has since been amply confirmed, and its expression (*omne animal ex ovo*) has now passed into a physiological aphorism, yet it was not intended by Harvey precisely in the sense which is now given to it. Harvey never saw the unimpregnated eggs of the quadrupeds, nor did he have any idea of the real structure and function of the ovaries in these animals; and in stating the opinion that the young of the vivipara and of man were produced from eggs, he only meant to say that after sexual intercourse and conception, the first thing produced in the uterus was not the embryo, but rather resembled an egg; and that the embryo was afterward formed from this by the process of growth. In 1672 Regnier de Graaf showed that the ovaries, in women and in female quadrupeds, were filled with globular vesicles, visible to the eye, similar in appearance to the eggs of birds and fishes. These vesicles he pronounced to be eggs; and the organs in which they were found then took the name of ovaries. A century and a half later (1827) Karl Ernst von Baer discovered by the microscope the real egg of the human female and of the viviparous animals, which is contained in the interior of the vesicles of De Graaf. These eggs were shown to exist in the ovaries of virgin females, as well as of those in whom sexual intercourse had taken place; and it was accordingly demonstrated that in all animals and in man the eggs are formed originally in the ovaries of the female, independently of the male, and that these eggs are afterward fecundated and developed into embryos. Another important discovery remained to complete our knowledge on this part of the subject, viz., that of the spontaneous ripening and discharge of the eggs, in quadrupeds and in man. Négrier (1840), Pouchet (1842), and Bischoff (1843) demonstrated that the eggs of the female, originally produced in the ovaries, ripen and are discharged, independently of sexual intercourse, at certain regular periods; and that the impregnation of these eggs by the male sperm is a subsequent process, taking place after the eggs have left the ovary and entered the Fallopian tubes. The origin of the embryo accordingly takes place in the same manner in all classes of animals, viz.: from an egg, which is produced in the ovary of the female, discharged thence at certain definite periods, and afterward fecundated by contact with the spermatic fluid of the male; and the only real difference between oviparous and viviparous animals is that in the former species (ovipara) the fecundated egg is discharged from the body of the female and

deposited in the nest, or other suitable receptacle, in which it is afterward hatched; while in the latter (vivipara) it is retained in the body of the female, and there nourished during the development of the embryo. The egg, at the time of its discharge from the ovary, consists of a globular vitellus or yolk, surrounded by a membrane termed the vitelline membrane,

Mammalian Egg, highly magnified.

a. Vitelline membrane. b. Vitellus. c. Germinative vesicle. d. Germinative spot. In the left-hand figure the egg is shown burst open by the rupture of the vitelline membrane and the vitellus partly escaping.

and containing a spherical vesicle termed the "germinative vesicle," marked with the "germinative spot." In very many instances this becomes surrounded, while passing downward through the Fallopian tubes or ducts, with a layer of transparent albuminous matter; as for example, in the eggs of frogs, tritons, &c. In other cases, in addition to the albuminous matter, certain membranous coverings are deposited round the egg, of a fibrous and calcareous texture, as in birds and the scaly reptiles. In all instances, however, it is the vitellus which is the essential part of the egg, and that from which the embryo is directly produced.—The first change which occurs after the impregnation of the egg is a spontaneous division or segmentation of the vitellus. The vitellus divides successively into smaller and smaller portions, in such a way as to produce at last a multitude of minute flattened bodies or cells, which are attached edge to edge, and which form accordingly a continuous membrane, which is called the blastodermic membrane. In eggs which have a large-sized yolk, as those of the birds, lizards, and turtles, the formation of the blastodermic membrane begins at a particular spot on the surface of the vitellus, termed the *cicatricula*, and thence spreads in every direction, so as to enclose gradually all the rest of the yolk. But in those which are of minute size, as in quadrupeds and the human species, the whole vitellus is converted into the blastodermic membrane, which after its formation encloses only a small cavity filled with transparent, watery fluid. The blastodermic membrane then becomes variously altered and developed in different parts so as to form the various organs and tissues of the embryo. A line or furrow first shows itself in the thickest and most condensed portion, known as the primitive trace. This indicates the future situation of the spinal column; and the different parts of the vertebrae gradually grow around it, forming a chain of cartilaginous rings, with

transverse and oblique processes, which envelope the primitive trace or furrow, and convert it into a closed canal, large and rounded at the anterior extremity, or head, but narrow and pointed at the posterior extremity, or tail. In this canal the brain and spinal cord are formed and complete the development of their various parts. At the same time the remainder of the blastodermic membrane becomes more condensed and organized, forming the integument and muscles of the chest and abdomen; and these portions finally unite with each other in front, forming at the point of junction a longitudinal or rounded cicatrix, known as the umbilicus. The alimentary canal, formed in the interior of the abdominal cavity, is at first entirely closed; but two openings are afterward formed, one at the anterior extremity of the body, the other at the posterior. These openings become respectively the mouth and anus. In frogs, tritons, and some kinds of fish, all these changes take place after the eggs are discharged from the body of the female. In birds and turtles the segmentation of the vitellus and the formation of the blastodermic membrane are already far advanced at the time the eggs are laid. In the lizards, most serpents, and some kinds of cartilaginous fishes, the development of the embryo takes place partly while the egg is still in the generative passages of the female, and partly after its expulsion. In a few species of serpents, and in some fishes, the embryo is completely developed within the egg in the body of the female, so that the young are finally brought forth alive; while in all the warm-blooded quadrupeds, as well as in the human species, the fecundated egg is also retained in the uterus until the embryo is sufficiently developed to be born alive.—In the frog, the eggs are deposited in the early spring, in some shallow pool, freely exposed to the light and air. Immediately after their expulsion the albuminous matter with which they are surrounded absorbs water and swells up into a tremulous and gelatinous mass, which floats near the surface, with the eggs imbedded in its substance. The formation of the embryo then goes on as above described, and the young animal, at first curled up in the interior of the vitelline membrane, soon ruptures it and effects its escape. The body is at this time of an elongated form, terminating behind in a narrow, compressed tail. The integument is covered with vibrating cilia, which produce a constant current of fresh water over the surface of the body. Respiration is performed by gills, situated at the sides of the neck, which are at first exposed, but afterward become covered by a fold of integument. The muscular system is very feeble, and the young animal remains nearly motionless, attached by the mouth to the gelatinous matter around the eggs, upon which he feeds for several days. As he increases in size and becomes stronger, he abandons the spawn and swims about freely in the water, feeding upon the juices and tissues of aquatic vegetables.

The cilia with which the body was covered disappear. The alimentary canal is at this time very long in proportion to the size of the whole body, being coiled up in the abdomen in a spiral form. During the summer lungs are developed in the interior, and the young tadpole frequently comes to the surface to take in air. But the gills also continue in existence, and are still the most active organs of respiration. Toward the end of the season anterior and posterior extremities or limbs begin to grow; the posterior sprouting externally from each side, in the neighborhood of the anus; the anterior remaining concealed under the integument, just below the situation of the gills. The tadpole passes the winter in this transition state. The next spring the lungs increase in size, and the gills become less active as organs of respiration. The anterior extremities are liberated from their confinement by a rupture of the integument which covered them, and both anterior and posterior limbs grow rapidly in size and strength. The tadpole at this time, therefore, has both fore and hind legs and a tail. The tail early in the summer becomes atrophied, and finally withers and disappears altogether; while the limbs, and especially the hind legs, grow to a larger size. At the same time, the lungs attaining their full development and the gills finally disappearing, the tadpole is thus converted into a perfect frog, capable of living and moving upon the land as well as in the water. The tadpole swims by the tail and breathes by gills, while the frog swims by the legs and breathes by lungs. Simultaneously with these changes, the alimentary canal becomes very much shorter in proportion to the rest of the body, and the frog becomes carnivorous in its habits, living principally upon insects, which he is enabled to capture by the great development of his muscular system, and the rapidity and suddenness of his movements.—The process of development of the embryo consists, accordingly, in the successive formation and disappearance of different organs which are adapted to different modes of life. When these changes take place after the young embryo has left the egg, as in the case of the frog, and so produce marked alterations in the external form of the body, they are termed transformations or metamorphoses. Thus the egg of the butterfly, when first hatched, produces a caterpillar, or larva; an animal with a worm-like body, sluggish crawling movements, and no sexual apparatus, but furnished with largely developed digestive organs and a voracious appetite. This condition is succeeded by the pupa state, in which the animal changes its skin, losing the legs and bristles which were his locomotory organs, and becomes motionless and nearly insensible to external impressions, and stops feeding altogether. During this period another integument grows underneath the old one, with new legs and wings; and when the skin is again changed, the animal appears as a

perfect insect, or imago, capable of rapid and sustained flight, ornamented with brilliant colors, provided with different sensory and digestive organs and a well developed sexual apparatus.—In those instances where the hatching of the egg is a longer process, similar changes to the above take place while the embryo is still retained in its interior. At the same time certain other organs are formed in addition, which either disappear before the time of hatching, or are thrown off when the young animal leaves the egg. With turtles, for example, the eggs, consisting of the vitellus, albumen, and shell, are deposited in an excavation in the earth or sand, and allowed to hatch in these situations. With birds, they are placed usually in nests, formed of twigs, leaves, and fibres, and there kept constantly warmed and protected by contact with the body of the female parent. This process is termed incubation, and may be imitated artificially by keeping the eggs at a temperature of 104° F. and providing for the regular supply of fresh air and a proper regulation of the atmospheric moisture. During incubation the eggs of the common fowl lose 12 per cent. of their weight, of which 11 per cent. is due to the exhalation of moisture. They also absorb oxygen and exhale carbonic acid. The segmentation of the vitellus and formation of the blastodermic membrane, and of the organs of the embryo, take place for the most part according to the plan already described, but variations present themselves which make the process more complicated. The vitellus, for example, instead of being entirely surrounded by the abdominal walls, is divided into two portions by a constriction situated about its middle. One of these portions remains outside the abdomen of the embryo, though still connected with it by a narrow neck, and by blood vessels which ramify upon its surface. This sac, containing a portion of the vitellus, is called the umbilical vesicle. It supplies the embryo with nourishment during the whole period of incubation; for immediately after the egg is laid the albumen, which is at first gelatinous in consistency, begins to liquefy near the upper surface, and the liquefied portions are immediately absorbed into the yolk. The yolk, therefore, grows larger and more fluid than before, while the albumen diminishes in quantity, and loses its watery portions. The blood vessels of the embryo, ramifying over the surface of the vitellus and the umbilical vesicle, in their turn absorb the nutritious fluids from it, and convey them into the interior of the body, to be used in the formation of the tissues. At the end of incubation the albumen has disappeared and the umbilical vesicle has much diminished in size, while the body of the chick has increased at the expense of both; but the umbilical vesicle, containing the remains of the yolk, still exists, and is enclosed within the abdominal walls when the chick leaves the egg. In quadrupeds and the human species the umbilical

cal vesicle is much smaller in proportion to the body, and less important in function, than in birds and the scaly reptiles. In the human embryo the umbilical vesicle, always very small, diminishes rapidly soon after the end of the third month, and is hardly distinguishable during the latter period of gestation. In the egg of the fowl certain accessory membranes or envelopes begin to grow around the embryo at an early period. The first of these is the amnion, which is formed by a double fold of the blastodermic membrane, rising up about the edges of the body of the embryo, so as to surround it by a kind of circumvallation, or embankment. By continued growth these folds at last approach each other and meet over the back of the embryo, forming by their union and adhesion an enclosing membrane, or sac, which is the amnion. The amnion, therefore, is a membranous envelope, which is closed over the back of the embryo, but which remains open in front of the abdomen. About the same time a vascular, membranous diverticulum grows out from the alimentary canal, near its posterior extremity, and emerging from the open part of the abdomen turns upward over the back of the embryo, outside the amnion, and just inside the shell membranes. This vascular membrane is the allantois, an organ which surrounds the embryo in quadrupeds, birds, and some reptiles, and which serves as an organ of nourishment, or for the aëration of the blood. It first makes its appearance in the early stages of embryonic life, as we have mentioned, in the form of a protrusion or offshoot from the lower part of the alimentary canal. It rapidly increases in extent, protrudes further from the abdomen, spreads laterally in every direction, and thus finally envelops the body of the fetus; its edges, as they come in contact with each other from opposite directions, in many species becoming adherent, so as to form a continuous membrane. This membrane, which in the bird's egg is situated immediately underneath the shell, is abundantly supplied with blood vessels coming from the interior of the abdomen of the embryo, and returning thither after having ramified upon the surface of the allantois. It is by this means that the absorption of oxygen and exhalation of carbonic acid take place, which are so distinctly marked in the fowl's egg during the latter period of incubation. The allantois in these animals is accordingly an organ of respiration for the fetus. Toward the latter period of incubation the allantois becomes very closely adherent to the egg shell, and the shell itself grows thinner, more porous, and more fragile; whence it is believed that the allantois also serves to absorb calcareous matter from the shell, which it conveys into the interior of the body, to be used in the formation of the bones, the ossification of which takes place about this period. When the chick is sufficiently developed to leave the egg, usually at the end of the 21st

day, by a sudden movement it strikes its bill through the end of the attenuated and brittle egg shell, and by inhaling the air and continuing its struggles, finally extricates itself from the cavity of the shell, leaving the allantois adherent to its internal surface. The blood vessels of the allantois are torn off at the umbilicus, which afterward closes and unites by a permanent cicatrix.—Another important change which takes place in the development of birds and quadrupeds, in addition to those presented by frogs and fishes, is the formation of the urinary apparatus. In fishes and batrachians the urinary organs are two long glandular bodies situated on each side the spinal column, which are known as the Wolffian bodies, and which remain permanent throughout the life of the animal, no true kidneys ever being produced. But in birds and quadrupeds the Wolffian bodies, which are at first very large and important organs, disappear during the progress of embryonic development, while the kidneys are formed at the same time, and gradually take their place as urinary organs. The kidneys are accordingly substituted for the Wolffian bodies in these instances, very much as lungs are substituted for gills in the development of the frog.—In many species of quadrupeds the allantois attains a large size, and performs a very important function, during intra-uterine life. In the ruminating animals, cows, sheep, goat, deer, &c., it forms an elongated sac, taking the form of the uterine cavity, and lying in close contact with the lining membrane of the uterus. The cavity of this sac communicates with the cavity of the posterior part of the intestine, from which it was originally developed, and receives the secretion of the Wolffian bodies, and afterward of the kidneys. Its exterior is covered with a large number (60 to 80) of tufted vascular prominences, which are entangled with similar elevations of the uterine mucous membrane, called cotyledons; and the blood of the embryo, while circulating through these bodies, absorbs from the maternal vessels the materials requisite for its nutrition. In the pig the allantois is nearly smooth on its external surface, merely presenting transverse folds and ridges, which lie in contact with similar inequalities of the uterine mucous membrane. In the carnivorous animals its middle portion is shaggy and vascular, and entangled with the blood vessels of the uterus, while its two extremities are smooth and unattached. In the human embryo the amnion is formed in the same manner as already described; but the allantois, instead of constituting a hollow sac, with a cavity containing fluid and communicating with the intestine, spreads out into a continuous flattened membrane, the two layers of which are in contact with each other and adherent, leaving consequently no cavity between them. It extends, however, quite round the fetus, enveloping it in a continuous vascular membrane, which here takes the name

of the chorion. The chorion is, accordingly, the same thing in the human species as the allantois in the lower animals, except that its cavity is obliterated by the adhesion of its walls. It is covered uniformly at an early date with tufted villousities, which become entangled with the mucous membrane of the uterus. But during the third month it begins to grow smooth over the greater portion of its surface, while at a certain part the villous tufts grow more rapidly than before, until they are finally converted into a thick vascular, spongy, and velvety mass of villousities, which penetrate into the uterine mucous membrane, and become adherent to its blood vessels. This organ is then termed the placenta; and from that time forward it serves the fœtus as an organ of absorption and nourishment, its blood vessels imbibing from the circulation of the mother the albuminous fluids which it requires for growth and nutrition.—The amnion in the human species is at an early period so arranged that it closely invests the body of the embryo, while between it and the chorion there is interposed a thick layer of soft gelatinous material. During the second and third months the cavity of the amnion enlarges, by the accumulation of a watery and albuminous fluid (the amniotic) in its interior, while the gelatinous matter between it and the chorion is gradually absorbed and disappears, in order to make way for its expansion. By this enlargement the amnion approaches nearer the internal surface of the chorion, and by the beginning of the fifth month the two membranes come in contact with each other. By this means the fœtus becomes enclosed in a large cavity (the amniotic cavity), filled with fluid, so that a free space is allowed for the movements of the fetal limbs. These movements begin to be perceived about the fifth month, at which time quickening is said to take place. They afterward become more strongly pronounced, and before birth are frequently very active. These movements are also favored by the formation and growth of the umbilical cord. The blood vessels of the fetus, termed the umbilical vessels, which pass out from the abdomen to the placenta and the chorion, become much elongated, and at the same time covered with a deposit of firm gelatinous matter, the whole being surrounded by a prolongation of the membrane of the amnion. This bundle of vessels, covered with the above investments, is termed the umbilical cord. It grows very long, and also becomes spirally twisted upon its own axis, usually in a direction from right to left. There are in the latter periods of gestation two umbilical arteries, carrying the blood of the fetus outward to the placenta, and one umbilical vein, in which it is returned to the body and the internal venous system.—The formation of the blood and blood vessels in the embryo takes place at a very early period. Soon after the production of the blastodermic membrane, some of the cells of which it is

composed break down, or separate from each other in such a manner as to leave irregular spaces, or canals, which insinuate with each other by frequent communications. These canals are destined afterward to become the blood vessels, the structure of which is gradually perfected by the growth of fibrous tissue in their walls, and their complete separation from the neighboring parts. In the interior of these canals, or imperfectly formed blood vessels, there is to be seen at first only a transparent, colorless fluid, holding in suspension a few large, roundish, nucleated cells, which move sluggishly to and fro, as the current of the circulating fluid begins to be established. These cells do not differ much at this period from those which constitute the general mass of the neighboring tissues; but soon afterward they begin to be modified in their appearance, and give place to true blood globules. Their surface becomes smooth, and a reddish coloring matter is produced in their interior, which gives them a tinge similar to that of the red globules of the blood in the adult condition. The red blood globules of the fœtus, however, still differ in several important particulars from those of the adult. They are considerably larger and more globular in shape, and have also a very distinct nucleus, which is wanting in the blood globules of the adult, at least in the quadrupeds. They increase in numbers also at this time by spontaneous division, one globule becoming divided into two, which separate from each other and afterward become themselves divided in a similar manner. In this way the quantity of the blood globules is very rapidly increased, and they soon become also still further altered in form and structure. They diminish in size, become in the human subject and the quadruped flattened and biconcave in form, and finally the nucleus disappears. These changes are all effected during fetal life, and chiefly during the early months, so that at the time of birth the blood globules have already the characteristics which distinguish them in adult life. The multiplication of the blood globules by subdivision is a process which takes place only in the embryo. The perfectly formed blood globules increase in number in some other way, probably by the isolated production and growth of new cells.—At the time of birth the fœtal membranes (amnion and chorion) are ruptured, and the fetus escapes. The umbilical cord being at the same time divided and tied, the portion still connected with the fetus soon shrivels and separates by spontaneous ulceration, while the spot at which it was attached heals in a few days, leaving a cicatrix on the middle of the abdomen, which is permanent throughout life, and which is called the umbilicus.—The limbs grow, by a kind of budding or sprouting process, from the side of the body. They are at first mere rounded eminences, without distinction of parts or articulations; but they subsequently become successively divided into fingers and toes, and

the different joints of the arm and leg. The upper extremities during the greater part of fetal life are larger than the lower, but afterward the lower extremities and the pelvis grow faster than the arms and shoulders, and finally become after birth much the larger of the two. The lungs are small and solid in texture before birth, but immediately afterward they expand by the inhalation of air, and receive a much larger supply of blood than before. On the other hand, the liver is much larger in proportion to the rest of the body at an early period than subsequently. In some animals it amounts during the first part of fetal life to 12 per cent. of the entire weight of the body, and is reduced to 3 or 4 per cent. at the time of birth. In the human subject it is equal at birth to $3\frac{1}{2}$ per cent. of the entire weight, but is reduced in the adult to less than 3 per cent. Great changes take place also during fetal life in the anatomy of the heart and circulatory system, as well as in the relative size and development of nearly all the organs in the body. These changes continue to take place after birth, though less rapidly than before, and the entire process of development is not regarded as complete until the individual has reached the adult condition.—A very singular modification of the above process of embryonic development among the mammalia occurs in the marsupial animals, of which the American opossum (*Didelphys Virginiana*) is a representative. In these animals the eggs are impregnated and the formation of the embryo commenced in the usual way; but after remaining for a comparatively short time in the uterus, and while their development is still very incomplete, the embryos are discharged from the generative passages, and are immediately afterward found attached by the mouth to the teats of the parent. They are then less than half an inch in length, and quite gelatinous and embryonic in appearance. They are protected by a double fold of the integument of the abdomen, which forms a kind of pouch, surrounding the teats, and serving to enclose the young and helpless embryos. They remain in this situation during the completion of their development, continuing attached for the most part to the teats, from which they derive nourishment; and even after they have become capable of running about by themselves, they still, upon an alarm, take refuge for a time in the pouch as before. It is not known how the young embryos, when expelled from the uterus, find their way into the external pouch so as to reach the teats, for, notwithstanding many attempts have been made to ascertain this point, the animal is so secret in her habits at the time of delivery that they have been thus far entirely unsuccessful.—Among invertebrate animals the egg is constituted, as a general thing, in nearly the same way as in vertebrata, and its impregnation takes place also in a similar manner. The segmentation of the yolk goes on by repeated subdivisions, until the whole vitellus is converted into a mulberry-shaped mass out of which the embryo is formed.

While, however, in the vertebrate animals, the embryo always lies with its belly upon the surface of the yolk, in some of the invertebrates, as the articulates (insects, spiders, crustaceans), the back of the embryo is in contact with the yolk, and the closing up or union of the two sides of the body takes place along the dorsal line, instead of the abdominal. In many mollusks, as for example in snails, the embryo, soon after the commencement of its formation, begins to rotate slowly in the interior of the vitelline sac; and this rotation continues more or less rapid until the hatching of the egg. In the invertebrate classes the metamorphoses or transformations of the young animal are more frequent and more striking than in vertebrata. In many of them the young animal when first hatched from the egg is entirely unlike its parent in structure, external appearance, and habits of life. In the class of insects many of these transformations are well known, and have always attracted the attention of the curious. Frequently the young animal, in passing through several successive transformations in which he is adapted to different modes of life, necessarily changes his habitation; and being found accordingly in totally different localities, and presenting at successive intervals corresponding differences of organization, the same embryo at different ages is often mistaken by the ignorant for an entirely distinct species of animal. These changes of habitation, occurring in the course of embryonic development, are termed migrations. They are often very marked in parasitic animals. Thus the tænia, or tapeworm, inhabiting the small intestines of certain animals, such as the dog, cat, &c., produces an egg containing a small globular embryo, armed with certain hard spikes, or curved prominences, capable of being moved by muscular fibres inserted into their base. The portion of the tapeworm in which these eggs are contained, known as the proglottis, is discharged from the intestine of the first animal, and the eggs, becoming mixed with vegetable matter, are devoured by animals belonging to other species, as for example the pig. Either in the process of mastication, or by the action of the digestive fluids of the stomach, the external envelope of the egg is destroyed, and the embryo set free. By means of its movable projecting spines, the embryo then makes its way through the walls of the stomach or intestine into the neighboring organs, and often reaches distant parts of the body. Here, becoming arrested, it is temporarily fixed in place by the consolidation of the tissues round it, and becomes enlarged by the imbibition of fluid, assuming a vesicular form. A portion of this vesicle becomes inverted, and at the bottom of the inverted part a head is produced, upon which there are formed four muscular disks, or suckers, and a circle of calcareous spines or hooks, different from those present at an earlier period, which are thrown off and lost. In this state the animal receives the name of *scolex* or

cysticercus. It remains in that condition till the death of the animal whose tissues it inhabits, when, being devoured with the flesh by an animal belonging to the first species, it passes into the intestine of the latter, and there becomes developed into the complete tapeworm, or *strobila*, similar to that from which its embryo was first produced. The same animal is accordingly a parasite in different organs, and even in different species, at different periods of its development. Some of the invertebrata are parasitic at one stage of their existence, and lead an independent life at another. Such are the small crustacea which infest the bodies and gills of certain fishes. In the family of *æstrida*, or bot flies, the eggs are deposited by the female insect, and attached to the hairs of horses, cattle, &c.; from which situation, after the embryo has become partly developed, they are detached in some instances (as in *gastrophilus equi*) by licking, and swallowed into the stomach. Here the larva is set free, and attaches itself to the mucous membrane of the stomach, nourishing itself upon the fluids obtained from this source, and gradually increasing in size. After a certain period the larva lets go its hold, passes through the intestine, is discharged with the feces, and, assuming the pupa state, is finally transformed into the perfect insect. The process of embryonic development is accordingly a succession of changes, in which the structure and organization of the young animal are adapted to different modes of existence, and in which different organs and apparatuses, successively appearing and disappearing, replace each other in the progress of growth, and give rise to the appearance of transformations, which affect the body as a whole.—See Harvey, *Exercitationes Anatomicae de Generatione Animalium* (London, 1651; Sydenham edition, London, 1847); Spallanzani, *Saggio di osservazioni microscopiche*, &c. EMBURY, Emma Catharine, an American authoress, born in New York in 1806, died in Brooklyn, N. Y., Feb. 10, 1863. She was the daughter of Dr. James R. Manley of New York, and was married to Mr. Daniel Embury in 1828. In the same year she published "Guido and other Poems." She frequently contributed to periodicals poems and tales, most of which afterward appeared in a collected form, under the titles of "The Blind Girl and other Tales," "Glimpses of Home Life," and "Pictures of Early Life." In 1845 she supplied the letter-press, both prose and verse, to an illustrated gift book entitled "Nature's Gems, or American Wild Flowers," and in the succeeding year published a collection of poems called "Love's Token Flowers." In 1848 she published "The Waldorf Family, or Grandfather's Legends," a fairy tale of Brittany, partly a translation and partly original.

EMBURY, Philip, the first Methodist minister in America, born in Ballygaran, Ireland, Sept. 21, 1729, died at Camden, Washington co., N. Y., in August, 1775. He was of German parentage, was educated at a school near Ballygaran, and learned the carpenter's trade. In 1758 he joined the Irish Methodist conference as a preacher. He emigrated to America in 1760, settled in New York as a carpenter, and in 1766, upon the advice of Barbara Heck, commenced preaching, first in his own house, and soon after in a rigging loft, afterward famous as the birthplace of Methodism in New York. The first Methodist church was erected under his charge in 1768, on the site of the existing John street church, he himself working upon the building as a carpenter. He preached here without salary until the arrival in 1769 of missionaries sent out by Wesley, when he resigned and emigrated to Camden, where he worked at his trade during the week, and preached on the Sabbath. He organized a Methodist society, chiefly of Irish emigrants, at Ashgrove, seven miles distant from Camden, being the first Methodist organization within the bounds of what is now the Troy conference. He died suddenly, in consequence of an accident in mowing, and was buried on a neighboring farm; but in 1832 his remains were removed to Ashgrove churchyard, and in 1866, by order of the Troy conference, to the Woodland cemetery, Cambridge, N. Y.

EMDEN, or **Embsen**, a seaport town of Prussia, in the province of Hanover, on the Dollart estuary, near the mouth of the Ems, 45 m. N. W. of Oldenburg; pop. in 1871, 12,588. The harbor is shallow, but the roadstead is capable of accommodating large vessels. Canals

intersect the town in various directions; one connects it with the town of Aurich, and another (opened in 1847, at a cost of \$300,000) with the Ems. It is protected by a high and strong embankment against the incursions of the Dollart, from which it has frequently suffered. Although the town has declined in population and prosperity, it continues to be the most important commercial town of Hanover. About 400 vessels enter and leave the port annually, and ship building is extensively carried on. Emden is of very ancient origin, and resembles more a Dutch than a German town. In the present century it has passed through the hands of Prussia, Holland, and France, came to Hanover in 1815, and in 1866 was again incorporated with Prussia.

EMERALD (Sp. *esmeralda*; Gr. *σμάραγδος*, from *σπαράσσειν*, to shine, whence the old name of smaragd and the German *Smaragd*), a name given to the finest crystals of the mineral species beryl, transparent and of rich green colors derived from oxide of chrome, which is present in the proportion of about 1 per cent., but, according to Vauquelin, sometimes as much as 3·5 per cent. (See BERYL.) They are found in metamorphic rocks, the granites, and mica schists. The finest specimens come from near Muzo, N. N. W. of Bogotá, South America. Here it occurs in isolated crystals or in nests in a clay slate, a rock containing cretaceous fossils in its limestone concretions, and not in veins, as has been stated. A perfect hexagonal crystal from this place, 2 in. long and measuring across its three diameters $2\frac{1}{2}$, $2\frac{1}{2}$, and $1\frac{1}{2}$ in., and weighing 8 oz. 18 dwts., is in the cabinet of the duke of Devonshire. A still finer specimen, but only 6 oz. in weight, is in the possession of Mr. Hope, and cost £500. Emeralds of much larger size, but of less beauty, are found in Siberia, on the river Tokovoya, in mica schist. One in the royal collection is $14\frac{1}{2}$ in. long by 12 broad, and weighs $16\frac{3}{4}$ lbs. troy. The true emeralds of the ancients are said to have been principally obtained from Mt. Zabarah in Upper Egypt, where the old workings were discovered by the French traveller M. Cailliaud, and reopened by Mehemet Ali. They are, however, inferior to the South American gems. The Peruvian emeralds were famous from the time of the conquest of that country by Pizarro. They were obtained in the barren district of Atacama, and worked by the native artists with the skill of the modern lapidary. To this day a river and a village of Ecuador are known by the name of Esmeraldas, from the abundance of emeralds formerly found in that region. Mexico at the same early period had produced crystals of rare beauty, which were no less appreciated and highly valued by the rulers of the Aztecs than were those of Peru by its incas. For one of the fine emeralds brought by Cortes on his return to Europe some Genoese merchants are said to have offered him 40,000 ducats. They had been cut by the exquisite workmanship of the

Aztecs, one in the form of a rose, the second in the form of a horn, the third like a fish with eyes of gold, and the fourth like a little bell, with a fine pearl for the tongue; the fifth, which was the most valuable, was a small cup with a foot of gold, and with four little chains of the same metal attached to a large pearl as a button. From these sources were probably obtained the magnificent emeralds now in the royal collection at Madrid, some of which are stated to be as large as those of the duke of Devonshire, and of the finest water. The emerald has long been highly esteemed, ranking in value next to the diamond and the ruby. Pliny states that in his time those of considerable size, which were free from defects, were sold at enormous prices.—The color of the emerald is of a finer green than that of any other stone, having different shades, some of verdigris or grass green, and some of a paler hue. They all appear best by daylight, and to retain their effect by candle light they require to be set with small diamonds or pearls. Emeralds are generally cut in the form of a square table, with bevelled edges, the lower surface being cut into facets, parallel to their sides. Beudant, in his *Minéralogie*, gives the value of emeralds of fine colors, and free from flaws, as follows: one of 4 grains, 100 to 120 francs; of 8 grains, 240 francs; of 15 grains, as high as 1,500 francs; and he cites a fine stone of 24 grains which was sold at 2,400 francs.—Immense emeralds are mentioned by ancient authors, but they were undoubtedly glass imitations. Such was the colossal statue of Serapis in the Egyptian labyrinth, 13½ ft. high; also an obelisk in the temple of Jupiter, 60 ft. high and 6 ft. broad, composed of four pieces. Sir J. Gardner Wilkinson remarks that the forming of these huge blocks of glass was a greater triumph of art than imitating the stones. Egypt was the country especially noted for the manufacture of artificial emeralds, and Pliny says that they succeeded so completely that it was "difficult to distinguish false from real stones."—The oriental is not, like the true emerald, a silicate of alumina and glucina, but is a green, transparent variety of corundum, and therefore nearly pure alumina, differing from the sapphire only in color. It is the rarest of gems, and from this and its superior hardness, although inferior in color, it is highly prized. Mr. Emanuel of London says that he has only met with one specimen; but in the autumn of 1872 Dr. J. Lawrence Smith had sent to him from the territory of Montana a quantity of rolled pebbles, which were found to be corundum. They were flattened hexagonal prisms with worn edges, and were either colorless or green, varying in shade from light to dark; none were red. They are found on the Missouri river, near its source, about 160 m. above Benton, and are obtained from bars on the river, where considerable gold is also found. The corundum is scattered through the gravel, which is about 5 ft. in depth, lying upon the bed rock. It is

most abundant on the Eldorado bar, 16 m. from Helena. One man could collect on this bar from one to two pounds per day. Dr. Smith has had some of the stones cut, one of them very perfect, of 3½ carats, of a fine green, almost equal to the best oriental emerald.

EMERALD HILL, a municipal town of Victoria, Australia, 1½ m. S. of Melbourne; pop. in 1871, 17,121. It has a mechanics' institute with a library of 2,350 volumes, several public buildings, and a weekly newspaper. It was one of the earliest municipalities of the colony, being proclaimed in May, 1855.

EMERSON, George Barrell, an American educator, born in Kennebunk, York co., Maine, Sept. 12, 1797. He graduated at Harvard college in 1817, and soon after took charge of an academy in Lancaster, Mass. Between 1819 and 1821 he was the tutor in mathematics and natural philosophy in Harvard college, and in 1821 was chosen principal of the English high school for boys in Boston. In 1823 he opened a private school for girls in the same city, which he conducted till 1855, when he retired from professional life. He wrote the second part of the "School and Schoolmaster," of which the first part was written by Bishop Potter of Pennsylvania, and is the author of a number of lectures on education. He was for many years president of the Boston society of natural history, and was appointed by Gov. Everett chairman of the commissioners for the zoölogical and botanical survey of Massachusetts. He has published a "Report on the Trees and Shrubs growing naturally in the Forests of Massachusetts" (Boston, 1846), and a "Manual of Agriculture" (1861).

EMERSON, Ralph Waldo, an American poet and essayist, born in Boston, Mass., May 25, 1803. He is the son of the Rev. William Emerson, pastor of the first church in that city. In his eighth year, on the death of his father, he was sent to one of the public grammar schools, and was soon qualified to enter the Latin school. Here his first attempts in literary composition were made, consisting of original poems recited at exhibitions of the school. He entered Harvard college in 1817, and graduated in August, 1821. He does not appear to have held a high rank in his class, though the records show that he twice received a Bowdoin prize for dissertations, and once a Boylston prize for declamation. He was also the poet of his class on "class day." While at the university he made more use of the library than is common among students, and was distinguished among his classmates for his knowledge of general literature. For five years after leaving college he was engaged in teaching school. In 1826 he was "approved to preach" by the Middlesex association of ministers; but his health at this time failing, he spent the winter in South Carolina and Florida. In March, 1829, he was ordained as colleague of Henry Ware, at the second Unitarian church of Boston. He belongs to a clerical race. For eight

generations, reckoning back to his ancestor Peter Bulkley, one of the founders of Concord, Mass., there had always been a clergyman in the family, either on the paternal or maternal side. He was the eighth in succession of this consecutive line of ministers. In 1832 he asked and received a dismission from the second church, on account of differences of opinion between himself and its members touching the Lord's supper; and in December he sailed for Europe, where he remained nearly a year. On his return in the winter of 1833-'4 he began his career as a lecturer, with a discourse before the Boston mechanics' institute on the subject of "Water." Three others followed, two on Italy descriptive of his recent tour in that country, and the last on the "Relation of Man to the Globe." In 1834 he delivered in Boston a series of biographical lectures on Michel Angelo, Milton, Luther, George Fox, and Edmund Burke, the first two of which were afterward published in the "North American Review." In this year also he read at Cambridge a poem before the Phi Beta Kappa society. In 1835 he fixed his residence at Concord, Mass., where he has since lived. During the winter he delivered in Boston a course of 10 lectures on English literature. These were followed, in 1836, by 12 lectures on the philosophy of history; in 1837, by 10 lectures on human culture; in 1838, by 10 lectures on human life; in 1839, by 10 lectures on the present age; in 1841, by 7 lectures on the times; and since that period he has delivered several courses of lectures in Boston. A small volume entitled "Nature" (1836), an oration before the Phi Beta Kappa society, with the title of "The American Scholar" (1837), an address to the senior class of the Cambridge divinity school (1838), and "The Method of Nature" (1841), contained the most prominent peculiarities of his scheme of idealism, and by their freshness and depth of thought, and compact beauty of expression, allured many readers into becoming disciples. In 1840 a quarterly periodical called "The Dial" was commenced, with Miss Margaret Fuller as editor, assisted by A. B. Alcott, William H. Channing, Mr. Emerson, Theodore Parker, George Ripley, and others. It was published for four years, and during the last two years of its existence it was under the editorship of Mr. Emerson. In 1841 the first, and in 1844 the second series of his "Essays" were published. In 1846 he collected and published a volume of his poems. The next year he visited England to fulfil an engagement to deliver a series of lectures before a union of mechanics' institutes and other societies. In 1849 he collected in one volume entitled "Miscellanies" his "Nature" and nine lectures and college addresses, which had been previously issued in pamphlet form, or printed in "The Dial." In 1850 "Essays on Representative Men," a series of masterly mental portraits, with some of the features overcharged, was published. To the "Memoirs of Margaret

Fuller Ossoli," which appeared in 1852, he contributed some admirable interpretative criticism. In 1856 he published "English Traits," a work in which he seizes and emphasizes the characteristics of the English mind and people; and in 1860 "The Conduct of Life." His contributions to the "Atlantic Monthly" have been collected. "May Day and Other Pieces" (poems) appeared in 1867; "Society and Solitude" in 1870. A revised edition of his "Prose Works Complete" was published in 1869. Mr. Emerson has also delivered many unpublished addresses on slavery, woman's rights, and other topics of public interest; and he has been one of the most prominent of the lecturers who address the lyceums of the country.—As a writer, Mr. Emerson is distinguished for a singular union of poetic imagination with practical acuteness. His vision takes a wide sweep in the realms of the ideal, but is no less firm and penetrating in the sphere of facts. His observations on society, on manners, on character, on institutions, are stamped with sagacity, and indicate a familiar knowledge of the homely phases of life, which are seldom viewed in their poetical relations. One side of his wisdom is worldly wisdom. The brilliant transcendentalist is evidently a man not easy to be deceived in matters pertaining to the ordinary course of human affairs. His common-sense shrewdness is vivified by a pervasive wit. With him, however, wit is not an end, but a means, and usually employed for the detection of pretence and imposture. Mr. Emerson's practical understanding is sometimes underrated from the fact that he never groups his thoughts by the methods of logic. He gives few reasons, even when he is most reasonable. He does not prove, but announces, aiming directly at the intelligence of his readers, without striving to extract a reluctant assent by force of argument. Insight, not reasoning, is his process. The bent of his mind is to ideal laws, which are perceived by the intuitive faculty, and are beyond the province of dialectics. Equally conspicuous is his tendency to embody ideas in the forms of imagination. No spiritual abstraction is so evanescent but he thus transforms it into a concrete reality. He seldom indulges in the expression of sentiment, and in his nature emotion seems to be less the product of the heart than of the brain. Mr. Emerson's style is in the nicest harmony with the character of his thought. It is condensed almost to abruptness. Occasionally he purchases compression at the expense of clearness, and his merits as a writer consist rather in the choice of words than in the connection of sentences, though his diction is vitalized by the presence of a powerful creative element. The singular beauty and intense life and significance of his language demonstrate that he has not only something to say, but knows exactly how to say it. Fluency, however, is out of the question in a style which combines such austere economy of words with the determination to

load every word with vital meaning. But the great characteristic of Mr. Emerson's intellect is the perception and sentiment of beauty. So strong is this, that he accepts nothing in life that is morbid, uncomely, haggard, or ghastly. The fact that an opinion depresses, instead of invigorating, is with him a sufficient reason for its rejection. His observation, his wit, his reason, his imagination, his style, all obey the controlling sense of beauty, which is at the heart of his nature, and instinctively avoid the ugly and the base. Those portions of Mr. Emerson's writings which relate to philosophy and religion may be considered as fragmentary contributions to the "Philosophy of the Infinite." He has no system, and indeed system in his mind is associated with charlatanism. His largest generalization is "Existence." On this inscrutable theme his conceptions vary with his moods and experience. Sometimes it seems to be man who parts with his personality in being united to God; sometimes it seems to be God who is impersonal, and who comes to personality only in man; and the real obscurity or vacillation of his metaphysical ideas is increased by the vivid and positive concrete forms in which they are successively clothed.

EMERY, an impure, granular variety of corundum, intimately mixed with hematite or with magnetic iron ore. It has the appearance of fine-grained iron ore, for which it was long mistaken. Often the crystals of corundum are separable by washing. Its extreme hardness, derived from the corundum, and the ease with which it is obtained in large quantities, have led to its extensive use in the arts, for grinding and polishing hard stones, metals, and glass. Some of the localities from which it is obtained in the Grecian archipelago, and in the vicinity of Smyrna and ancient Ephesus in Asia Minor, were probably known to the ancient Greeks and Romans, as the use of a substance of this nature seems to have been required by the lapidaries of Magnesia, Ephesus, Tralles, and Tyre. In later times the island of Naxos in the archipelago has furnished all the supplies of commerce, the mineral being shipped from the port of Smyrna, and known by the name of Smyrna emery. From 1835 to 1846 the trade in emery was a monopoly granted by the Greek government to an English merchant, who so regulated the supply as to raise the price from its former rate of \$40 a ton to about \$140. This monopoly was broken up and the whole trade changed in consequence of the discoveries of Dr. J. Lawrence Smith of the United States, who in the course of his explorations in the service of the Porte discovered in 1847 a number of localities of the mineral belonging both to the Turkish and Greek governments. By an arrangement with the former, operations were commenced in the same year at some of the localities and afterward extended to others, so that the price has since been reduced to \$60 a ton. At the Juma Dag, 12 m. E. of the ruins of Ephesus, Dr. Smith found the

emery scattered about upon the summit in loose pieces of all sizes up to masses of several tons weight. The rock to which it belongs is a bluish metamorphic marble, reposing upon mica slate and gneiss. In this rock the mineral is found in nodules and in amorphous masses, some of which are several yards in length and breadth, and of the weight of 30 to 40 tons. The structure of this rock is compact and tolerably regular, but the surface presents a granular appearance. Unless traversed by fissures, the rock is broken with great difficulty, and attempts to drill it are made in vain from its wear upon the tools. As the transportation from the quarries is only on the backs of camels or horses, many of the heavier masses are necessarily left behind. Some of the blocks, however, yield to the hammer after being exposed for some hours to the action of fire. The color of the powder varies from dark gray to black; but its shade has no relation to its hardness, and is consequently no index of the value of the article. The relative degrees of hardness of different samples were determined by Dr. Smith by collecting the powder just coarse enough to pass through a sieve of 400 holes to the inch, and with weighed samples of this rubbing little test plates of glass till they ceased to be further reduced. The rubber was the smooth bottom surface of an agate mortar. The loss in weight experienced by the glass plates gave the relative values of the samples of emery. On this plan Dr. Smith prepared a table exhibiting the different degrees of hardness; and making use of sapphire of Ceylon as the standard of comparison, the hardness of which he called 100, and the effective wear of which upon glass was equal to about four fifths of its own weight, that of the best emery was about one half of its weight. This table, to which were appended the results of the analyses of many samples of the mineral made by Dr. Smith, was published in the elaborate articles which he furnished to the "American Journal of Science," second series, vols. x. and xi. The hardness of the sapphire as rated upon the mineralogical scale is 9, next to the diamond, which is 10. That of emery is not necessarily indicated by the proportion of alumina, for a part of this may be in combination with the silica. It seems to vary with the water present, those samples containing the least water being the hardest. In 1855 the annual production of emery was 2,000 tons of Naxos stone and 1,600 tons of Turkish. The whole business was concentrated in the hands of Mr. Abbott, who held the contract with the Greek government, extending for ten years, and had purchased the Turkish firman, unlimited in time, for the annual payment of \$55,000. An arrangement was entered into with the house of Messrs. John Taylor and sons of England to employ a capital of £120,000 in this business, and supply the emery either in the stone or powder to all parts of the world, with the guaranty of its being free from adulterations,

such as had previously impaired its qualities and reduced its value.—The principal consumption of the article is in polishing plate glass, and the increase of this business causes a constantly increasing demand for emery. The discovery of new localities is a matter of great importance, the few that are known in other parts of the world furnishing no supply capable of competing with that brought from the head of the Mediterranean. It is said to be found near Petschau in Bohemia, near Yekaterinburg in the Ural, near Miyask in the Ilmen branch of that range, and in Frederick valley, Australia. An extensive vein of emery, exhibiting blue crystals of corundum, was discovered a few years ago at Chester, Mass., by Dr. C. T. Jackson of Boston. The mineral, which had for some time been mistaken for magnetic iron ore, occurs associated with margarite, diaspore, and chlorotoid, in talcose schist. The "American Journal of Science" for September, 1873, contains an article by Dr. J. Lawrence Smith giving an account of the discovery of beds of corundum containing emery in North Carolina, Georgia, and Montana. The beds in North Carolina are very extensive; the corundum is described as being very beautiful, and is found in masses weighing from 600 to 800 lbs., "having large cleavages, and being remarkably free from foreign ingredients," and in such quantities as to admit of its use as a substitute for emery. It occurs in chrysolite or serpentine rocks, belonging to a regular system of dikes lying on the N. W. side of the Blue Ridge, at an average distance from the summit of about 10 m., and which have been traversed for 191 m. Dr. Smith remarks that through all the range the corundum forms a geognostic mark of the chrysolite, as it does of the calcareous rock containing corundum, described by him in Asia Minor, and belongs to the same geologic epoch. For a notice of the Montana mineral, see *EMERALD*.—Emery is prepared for use by crushing the stone under stamps, and sorting the powder into different sizes by appropriate sieves. For the most delicate uses of opticians it is separated in a small way by a system of washing over called by chemists elutriation. After being ground, the powder is thrown into water, or water containing gum arabic, or it may be oil, and allowed to subside for a certain number of seconds or minutes. The process being systematically conducted, the powder is sorted into many sizes, and named according to the time the fluid is allowed to stand before the substance in suspension is collected, as emery of 10 seconds, of 30 seconds, 2 minutes, 30, 60, 80 minutes, &c. Emery is applied to paper, thin cloth, and slips of wood, by dusting the powder upon these articles after they have been coated with thin glue. They are then ready for sale or for use under the name of emery paper, cloth, or sticks. Mixed with paper pulp and fine glass and rolled into sheets, it forms the patent razor-strop paper; and by a variety of other methods

it is prepared for convenient application to its numerous uses of grinding and polishing.

EMETICS, medicines used to produce vomiting. They may be divided into two classes, specific and irritant. The first class require for their operation absorption into the circulation, and they produce their specific effects whether they are absorbed from the stomach or injected directly into the blood. When taken internally their action does not commonly commence until after 20 or 30 minutes; then nausea, chilliness, and a feeling of weakness are produced, while the pulse is slow and soft; and as vomiting is induced, these give way to a flushed countenance, a warm skin, and a full pulse. The most important of these are tartar emetic (tartrate of antimony and potash), ipecacuanha, and the lately discovered apomorphia, which is an artificial alkaloid, prepared, as its name indicates, from morphia. Tartar emetic has recently been supposed to produce its effect, like the second class, by an irritant action upon the mucous membrane of the stomach, to which it is either directly applied or by which it is excreted when injected into the blood. Apomorphia, when injected subcutaneously, acts with great rapidity and in much smaller dose than when given by the stomach. *Lobelia inflata*, or Indian tobacco, has been largely used as an emetic by botanic practitioners, but is exceedingly depressing in its effects. Irritant emetics, as sulphate of zinc, copper, mustard, &c., on the other hand, produce vomiting by their direct effect upon the lining membrane of the stomach. Their action is immediate and unpreceded by any nausea or other precursory symptoms. They are used chiefly in cases of narcotic poisoning, and of accumulation in the bronchial tubes, where from the feebleness of the patient it is desirable to shun the depression preceding the action of ordinary emetics, while full and prompt vomiting is required. Emetics were formerly used extensively in the treatment of a large variety of diseases; but the careful observation of recent times has greatly restricted their employment. They find their most appropriate use in relieving the stomach from an excess of food, or from indigestible food, and from poisons, and occasionally in the treatment of bronchitis and croup.

EMIGRATION (Lat. *e*, from, and *migrare*, to depart), the act of leaving the country or place where one has resided, in order to reside in another. The terms emigration and emigrant are strictly applicable only with reference to the country from which the migration is made, and the converse terms immigration and immigrant are used when express reference to the country into which it is made is intended; but in the unlimited sense of change of residence, the former are generally employed in connection with either the old or the new domicile.—Of the earliest migrations by which the fundamental features of European history have been defined, no records remain,

but numerous traces of them are found by the archæologist, ethnologist, and linguist. Emigration proper commenced when herdsmen congregated into nomadic tribes. Of such corporate emigration patriarchal history records some examples, as those of Abraham and Jacob. With the progress of agriculture and the growth of more definite political relations, trade, and commerce, began the emigration of single bodies of adventurers to distant countries. In this way, according to Hellenic traditions, Phœnicians, led by Cadmus, and Egyptians, led by Danaus and Cecrops, emigrated to Greece, the Heraclidæ from Greece to Asia Minor, and the Tyrrhenians to Italy. The exodus of the Israelites from Egypt to Canaan was a corporate emigration of a people, on account of religious and political oppression, for which modern history furnishes parallels in the Mormon emigration to Utah and the emigration of the Boers in southern Africa. During the historical times of ancient Greece emigration generally assumed the character of colonization. Many flourishing and powerful Greek colonies were thus sent forth along the shores of the Mediterranean and Black seas by Greece. The colonies of ancient Rome for the most part were rather outposts of an army and combinations of fortune hunters than settlements of men intending to found permanent residences. The great migration of the Germanic nations having destroyed the Roman empire, European society was for centuries subject to constant changes. Charlemagne changed the direction of German emigration from the south to the east and north. While from that time the movements of German nations toward Italy assumed the character of mere military conquests, their emigration conquered nearly the whole country between the Elbe and Vistula rivers from the Slavic race. A counter-current from Asia, which set in at various periods of the middle ages, consisting of Magyars and Tartars, was successfully resisted, and the tide was even turned upon Asia by the crusades; but at a later period another Asiatic race, the Osmanli Turks, succeeded in displacing the most decayed of Christian nations in southeastern Europe, while almost simultaneously still another Asiatic race (the Arabs) was expelled from the southwestern peninsula, Spain, to which they had emigrated eight centuries before.—In Europe, Russia was among the earliest to perceive the advantages of immigration. Peter the Great invited emigrants from all nations to settle in Russia. His successors followed the same policy by granting premiums and valuable privileges, such as exemption from taxation for a certain number of years, exemption from military duty, and free homesteads to colonists. Induced by these advantages, a large number of emigrants from the Palatinate settled in southern Russia about 1784. Immediately after the Napoleonic wars an extensive Germanic emigration to Russia (includ-

ing Poland) took place. The total number of Germans who emigrated thither between the years 1816 and 1826 is estimated at 250,000. The agricultural colonies of Vielovish in the government of Tchernigov, and Rieben-dorf in that of Voronezh, a manufacturing colony near Poltava, a Moravian settlement at Sarepta, and a number of German colonies in the Crimea, originated in this way. During the reign of Nicholas emigration to Russia ceased almost entirely, but it revived to a certain degree after the accession of Alexander II.—Individual emigration, as distinguished from the movements of nations, commenced on a large scale after the discovery of America. During the 16th century the nations in which the Roman element predominated, Spain, Portugal, and France, sent forth a great number of emigrants, most of them mere adventurers who did not intend to stay longer than might be necessary to become rich. The first attempts by the English to organize emigration to America likewise originated in adventurous designs. In such attempts 300 men and £40,000 were lost from 1585 to 1590. In 1606 more than 2,000 emigrants were sent from England to North America to seek for gold, but they perished miserably, and in 1609 but 60 remained. The Hakluyt company for the colonization of Virginia lost 9,000 men and £100,000. At last religious contests laid a firm foundation for the permanent settlement of the North American continent. The emigration of the Puritans and their successful establishment in New England served as an example to all those who in Europe were oppressed for the sake of their religion. Besides, the ground having been broken for the settlement of what are now the southern states of the Union, the fertility of their soil, their genial climate, and withal the still lingering hope of sudden enrichment by discoveries of precious metals, attracted large numbers of colonists. A strong tide of emigration from Germany set in toward Pennsylvania near the end of the 17th and during the 18th century; the Dutch colonized New York; the Swedes Delaware; Canada and Louisiana were settled by the French. Still the current of emigration to America during the 170 years of the colonial history was slow and tedious when compared with that which commenced after the war of independence, and especially when the success of American institutions had been tested by the experience of one generation. Since the formation of the government, the United States has been the principal point of emigration from Europe, and of late also from Asia, owing chiefly to the advantages presented to the laboring classes, who constitute the great bulk of emigrants. Immigration from whatever source has been regarded with favor by the government, and laws have been passed at different times for the regulation of emigrant ships and the protection and comfort of emigrants. During the latter part of the 18th and the early part of the 19th century

the practice prevailed in New York and Philadelphia of selling by public auction into temporary servitude emigrants who were indebted for their passage money and other advances. During the last century the prepayment of the passage by the emigrant was the exception, and its subsequent discharge by compulsory labor the rule. Ship owners and ship merchants derived enormous profits from this traffic, as they charged very high rates for the passage and added a heavy percentage for their risks. Adults were sold for a term of from 3 to 6 years, and children from 10 to 15 years. Servants signed indentures and were known as "indentured servants." The last sales of this kind took place in Philadelphia in 1818 and 1819.—During the early part of the present century there was little protection for emigrants during the sea voyage. Ship owners generally chartered the lower decks of their vessels to agents, who made temporary arrangements for the accommodation of the passengers, and either underlet the steerage to associations of emigrants or parcelled it out to sub-agents or to single passengers. These agents crowded emigrants into vessels without regard to their comfort or health, and there was no authority to which the latter could appeal for protection. As late as 1819 the lower deck of an emigrant vessel was no better than that of a slave or coolie ship. The ordinary height of the steerage deck was from 4 to 5 ft.; the lower, or orlop deck, which was also used for the transportation of passengers, was still worse. The natural consequence was a mortality frequently amounting to 10 and sometimes to 20 per cent. The first law which prescribed the space to be allotted to each steerage passenger was that passed by congress in March, 1819, which made it unlawful for a ship to carry more than two passengers for every five tons, custom-house measure. This law, however, did little toward reducing the hardships of the voyage, which was attended with much sickness and many deaths, the prevailing diseases being typhus or ship fever, cholera, and smallpox. In 1855 an act was passed by congress intended to secure the rights of emigrants on shipboard, by giving to each of them two tons of space, and providing for the proper ventilation of the ship, as well as for a sufficient amount of proper food; and this law has resulted in great amelioration. Another circumstance which has largely reduced the suffering and mortality during the voyage is the use of steamers instead of sailing vessels. In 1856 only about 3 per cent. of the emigrants came in steamers, while in 1873 more than 96 per cent. arrived in steamers and less than 4 per cent. in sailing vessels. The deaths in steamers were about 1 in 1,128 passengers, while the death rate in sailing vessels reached the significant ratio of 1 in 65. The port of New York is the great gate through which the emigration to the United States chiefly passes. Of the total number (437,004) of emigrants

in 1873, 266,818 entered at New York. Here exists the only thoroughly organized system in the country for their reception and protection. The extortions and frauds which had been practised upon emigrants arriving at New York, as well as the rapidly increasing tide of immigration, led to the passage by the legislature of the act of May 5, 1847, creating the board of commissioners of emigration of the state of New York, which has since been in successful operation. It consists of nine members, six of whom are appointed by the governor of the state with the consent of the senate, and three are members *ex officio*, viz.: the mayor of New York, the president of the German society, and the president of the Irish emigrant society. All the commissioners serve without compensation. Their duties are to protect alien passengers arriving at New York from fraud and imposition, to care and provide for the helpless among them, to give them trustworthy advice and information, and generally to guard their interests. To provide a fund for this purpose, the owner or consignee of any vessel carrying emigrants to New York is required to give a bond, with a penalty of \$300 for each alien passenger, to indemnify the commissioners and the state from any cost that may be incurred for the relief, support, or medical care of the person named in the bond during five years. In lieu of this bond he may pay a commutation, originally fixed at \$2 50, but in 1871 reduced to \$1 50, for each alien passenger brought into the port. For the more effectual protection of emigrants arriving at New York, an act was passed by the legislature in 1868, by which the commissioners of emigration are invested with authority to examine under oath any witness as to the condition of any ship, and the treatment of the emigrants while on board. The commissioners may also take testimony in reference to any death that may have occurred during the voyage; and such testimony, if made in the presence of the persons complained of, may be used as evidence in any subsequent action. The good intentions of the legislature, however, have not been realized, as the emigrants cannot afford the necessary time and money to enter into a long litigation against rich and powerful companies. The commissioners of emigration have therefore repeatedly and strongly urged congress to negotiate with foreign governments for the appointment of a joint high commission or court for the speedy adjudication of all cases relating to the treatment of emigrants while on board of a ship. Upon the arrival of an emigrant vessel at quarantine, six miles below the city, it is inspected by the health officer of the port, and the sick emigrants, if any, are transferred by steamer to hospitals, where they are cared for by the commissioners of emigration. If removed by authority of the health officers, they are taken to the quarantine hospital, where they are under charge of the quarantine commission. The vessel is then taken in charge by an officer

of the department who ascertains the number of passengers, the deaths, if any, during the voyage, and the amount and character of the sickness; he also examines the condition of the vessel in respect to cleanliness, and hears complaints by passengers; of all which he makes reports to the superintendent at Castle Garden. He remains on board the ship during the passage up the bay, to see that the passengers are not interfered with by any unauthorized person from the shore. After examination of their luggage by the customs officers the emigrants are transferred to the landing depot at Castle Garden, which was formerly a fortress defending the port, and was subsequently used as a place of amusement. It was opened as the emigrant landing depot in August, 1855, and is well adapted for the purpose. The emigrants are brought by barge or tug from the vessel in which they arrived, and after examination by a medical officer are ushered into the rotunda, a circular space comprising 50,000 sq. ft., and with a dome in the centre about 75 ft. high. It is well warmed, lighted, and ventilated, and will properly accommodate about 4,000 persons. Here the name, nationality, former place of residence, and intended destination of each individual, with other particulars, are registered. The newly arrived emigrant here finds facilities for supplying every immediate want without leaving the depot. The names of such as have money, letters, or friends awaiting them are called out, and they are put into immediate possession of their property or committed to their friends, whose credentials have first been properly scrutinized. There are clerks at hand to write letters for them in any European language, and a telegraph operator to forward despatches. Here, also, the main trunk lines of railway have offices, at which the emigrant can buy tickets, and have his luggage weighed and checked; brokers are admitted, under restrictions which make fraud impossible, to exchange the foreign coin or paper of emigrants; a restaurant supplies them with plain food at moderate prices; a physician is in attendance for the sick, and a temporary hospital ready to receive them until they can be sent to Ward's island; employment is provided by the labor bureau, connected with the establishment, to those in search of it; such as desire to start at once for their destination are sent to the railway or steamboat; while any who choose to remain in the city are referred to boarding-house keepers admitted to the landing depot, whose charges are regulated under special license, and whose houses are kept under supervision by the commission. Ample facilities for the care of sick and destitute emigrants are afforded by the institutions on Ward's Island, which are under the supervision of the commissioners of emigration. This island comprises about 200 acres in the East river, and extends opposite the city from 100th to 116th street; 121 acres, including the entire water front next to New York, are used for em-

igrant purposes, and the remaining portion is chiefly used by the commissioners of public charities and correction. The institutions embrace the hospitals, the refuge, the lunatic asylum, the nursery, dispensary, chapels, schools, workshops, &c. These institutions contain on an average about 2,000 inmates, the most of whom are more or less helpless. The chief building is the Verplanck hospital, which consists of a corridor 450 ft. long and two stories high, from which project five wings each 180 ft. long, 25 ft. wide, and two stories high except the centre wing, which has three stories; the corners of each wing are flanked with towers. It is constructed upon the most approved plans for perfect ventilation, and all necessary comforts for the sick. It has accommodations for about 500 patients, and is used exclusively for non-contagious diseases and surgical cases. A new lunatic asylum has recently been erected, with accommodations for more than 300 patients. The extent of the work done by the commission since its organization is indicated by the fact that of the 5,033,392 emigrants arriving at New York from May 5, 1847, to Jan. 1, 1873, for whom commutation money was paid, and all of whom received protection, advice, and information from the commissioners, 1,465,579 were provided and cared for out of the emigrant fund for a greater or less period during the five years subsequent to arrival. viz.: 398,643 received treatment and care in the institutions of the commissioners; 449,275 were supplied temporarily with board and lodging and money relief in the city of New York; 349,936 were provided with employment through the labor bureau at Castle Garden; 53,083 were forwarded from Castle Garden to their destination in the United States, or returned to Europe at their own request; and 214,642 were relieved and provided for in various parts of the state of New York at the expense of the commissioners of emigration. During 1873, 731 emigrant vessels from 23 different ports arrived at Castle Garden. In the labor bureau employment was procured for 25,325, including 7,504 females. Through the agency of the information bureau, about 12 per cent. of the total arrivals were delivered to their friends. The number cared for in the institutions on Ward's island was 12,586, including 2,134 receiving treatment at the beginning of the year; of this number 10,430 were discharged during the year, and 439 died, leaving 1,717 under treatment Jan. 1, 1874. The expenditures for the year amounted to \$466,108, including \$215,086 for support of the institutions on Ward's island, \$133,451 for expenses at Castle Garden, and \$61,188 for buildings and permanent improvements. The current expenses of the commission were \$510,306 in 1869, \$540,467 in 1870, \$518,387 in 1871, and \$461,028 in 1872. In addition to these sums, \$651,980 were expended during these four years in the erection of buildings and permanent improvements. These expendi-

tures are met by the funds realized from the commutation fund paid by owners or consignees of emigrant ships, which amounted to \$657,072 in 1869, \$534,056 in 1870, \$372,528 in 1871, \$442,429 in 1872, and \$402,199 in 1873. The emigrants are not considered or treated as paupers, but as persons requiring temporary aid and protection, for which neither the state nor any community is required to contribute. In 1872-'3 bills were introduced into congress to supersede the New York commission of emigration by a national bureau, thus vesting in the general government all control and regulation of this important subject; but the measures met with great opposition from the New York commissioners of emigration and others, and failed.—Prior to 1819 no official record was kept of the number and character of the persons coming to the United States from

abroad. The extent of the immigration prior to that date has been differently estimated by various authorities. Mr. Lorin Blodget thought the arrivals did not exceed 4,000 a year from 1789 to 1794. Dr. Adam Seybert estimated the number at 6,000 a year from 1790 to 1810. According to Prof. Tucker, whose estimate is confirmed by high authorities, 50,000 arrived from 1790 to 1800, 70,000 from 1800 to 1810, and 114,000 from 1810 to 1820; making 234,000 from 1790 to 1820. According to Mr. Young, chief of the United States bureau of statistics, the total number of arrivals prior to 1820 was 250,000, of whom 25,000 came between 1776 and 1790. In the following table are indicated the total number of alien passengers arriving in the United States in each year since 1820, and the chief countries from which they emigrated:

YEARS.	England.	Ireland.	Scotland.	Total British Isles.	British America.	Germany.	Prussia.	Holland.	Sweden and Norway.	France.	Switzerland.	Italy.	Total.

* Years ended Sept. 30. † 1832 and last quarter of 1831. ‡ Years ended Dec. 31. § First three quarters. ¶ Last quarter.

To obtain the net immigration from the preceding table, about 1½ per cent. of the total aliens should be deducted for those not intending to remain in the United States. Those who died during the voyage are included prior to 1867. Prior to 1871 the statements for Germany do not include the emigrants from Prussia and Austria. Since 1819 a law of congress has required that all who come to the sea and lake ports shall be registered at the custom houses. The number, age, sex, nativity, occupation, and destination of all passengers coming to the United States, distinguishing aliens from citizens returning from abroad, and those intending to remain from those who come merely for temporary purposes, are ascertained and reported to the general government. This information is compiled and published annually by the United States bureau of statistics. No official registration is made, however, of those foreigners who enter the country through other channels than the sea and lake ports, many of whom come across the border from Canada and New Brunswick. The following statement shows the principal countries represented in the emigration to the United States from 1820 to 1874, with the total number from each during that period and in 1873:

FROM	1873.	1820 to 1874.
Great Britain and Ireland	159,355	4,319,048
Germany (including Prussia).....	133,141	2,764,420

According to Mr. Young, 46 per cent. of the whole immigration, after deducting the women and children, had been trained to various pursuits, nearly half being skilled laborers and workmen. Nearly 10 per cent. consist of merchants and traders. The occupations of the

emigrants arriving in the United States from 1820 to Jan. 1, 1874, are shown in the following table, compiled by the United States bureau of statistics:

OCCUPATIONS.	1820-'30.	1831-'40.	1841-'50.	1851-'60.	1861-'73.	Aggregate.
Laborers	10,280	53,169	281,229	527,639	785,464	1,657,781
Farmers	15,005	88,240	256,880	404,712	318,434	1,083,271

Deduct citizens of the United States	24,649	40,961	54,924	276,473	460,623	857,630
Aliens	151,824	599,125	1,713,251	2,598,214	3,745,727	8,808,141

In respect of nationality, more than half of those having arrived are British, coming from the United Kingdom of Great Britain and Ireland and the British possessions in North America, and speaking the English language. The German element is next in magnitude, and embraces nearly two thirds of the remainder. A large proportion settle in rural districts and develop the agricultural resources of the west and south, while the remainder, consisting largely of artisans and skilled workmen, find employment in the cities and manufacturing towns. About 25 per cent. of the emigrants are under 15 years of age, and less than 15 per cent. over 40, leaving more than 60 per cent. in the prime of life. The number of males is largely in excess of that of females, the ratio varying with the nationality. Among the Chinese only about 7 per cent. are females, while their ratio among the Irish is over 45 per cent., and in the total number of emigrants about 40 per cent.—For several centuries there has been a great emigration from China to the surrounding countries, both by sea and land. Vast multitudes of Chinese have settled in Tartary, Thibet, Anam, Siam, Burmah, Malacca, and in Borneo, Java, Sumatra, the Philippine islands, and in short everywhere in the East Indian archipelago. But of these emigrants there are no accurate statistics. Of late years they have made their way in considerable numbers to Australia; and in 1853, attracted by the gold of California, they began to come to the United States, and their immigration has attained a magnitude worthy of at-

tention. The whole number who had arrived up to Jan. 1, 1874, was 144,328, nearly all of whom entered at San Francisco. Most of them have settled in California, where they are occupied chiefly in mining pursuits; but many have found their way to Nevada and some of the territories, and a few to the Atlantic and some of the other states. Nearly one half of all who have arrived have returned to their native country. According to the census of 1870, there were 63,199 Chinese in the United States, of whom only 4,566 were females; there were 49,277 in California, 4,274 in Idaho, 3,330 in Oregon, 3,152 in Nevada, and 1,949 in Montana. The number of arrivals, according to the United States bureau of statistics, is given below; those prior to 1855 are differently reported by another authority in the article CHINA:

YEARS.	No. of Im-migrants.	YEARS.	No. of im-migrants.
1853	42	1865	2,942
1854	13,100	1866	2,355
1855	3,526	1867	3,863
1856	4,733	1868	10,684
1857	5,944	1869	14,902
1858	5,123	1870	11,943
1859	3,457	1871	6,089
1860	5,467	1872	10,642
1861	7,513	1873	18,154
1862	3,693		
1863	7,214	Total	144,328
1864	2,795		

The Chinese emigration to the United States has been characterized by an organized system which is not found in the emigration from any European nation. The latter, as has been

seen, is entirely without system or organization, and the emigrant is wholly unrestrained as soon as he reaches his destination. The emigration from China, however, is controlled by men of large capital, who engage in it as a traffic. A contract is made with the emigrants in their native country by which they mortgage their future earnings to secure the cost of passage and other expenses, and which binds them to a specified term of service after arrival in this country. In many instances the Chinaman gives a mortgage on his wife and children, with a stipulation that at the end of his term of service he is to be brought back to China by his contractor. This contract is sold

or transferred to an agent in the United States at an advance, and is thus a source of great profit to the dealer. The agent contracts for the labor of the Chinese in any part of the United States. Perhaps the most prominent contractor of this kind has been Mr. Koopman-schap, who sought to introduce Chinese labor under this system into the southern states and other parts of the United States. The contract made in China has no validity in the United States, but it has always been strictly observed by both parties. The following table, from the census of 1870, exhibits the distribution by states and territories of the leading nationalities in the United States:

STATES AND TERRITORIES.	Aggregate population.	Total foreign.	British America.	England.	Ireland.	Scotland.	Wales.	France.	Germany.	Holland.	Switzerland.	Norway and Sweden.

—The variance in the magnitude of the emigration to the United States in different periods presents results of great interest and importance, and points to the causes that increase or diminish the movement from foreign countries.

Chief among these causes are war, political troubles, famine, commercial panics, and other influences which produce distress at home or an unfavorable condition of affairs in the country to which emigration is directed. The most

remarkable illustrations of this kind were presented by the great exodus from Ireland and that from Germany during the period 1845 to 1854, when the highest figures till then known in the history of emigration were reached. After the great famine of 1846, the emigration from Ireland to the United States, which had increased from 44,821 in 1845 to 51,752 in 1846, rapidly rose to 105,536 in 1847, 112,934 in 1848, 159,398 in 1849, and 164,004 in 1850. It reached its maximum in 1851, when 221,213 Irish emigrants arrived in the United States; and in the following year it decreased to 159,548. During the period from 1845 to 1854 inclusive, 1,512,100 Irish left their country for the United States, of whom 607,241 came during the first and 904,859 during the last half of the decade. Since 1854 the movement has fallen off to less than one half of the average of the preceding ten years. During this same period the emigration from Germany also culminated. This increase was very marked as early as 1845, when the number of German emigrants was 33,138; in 1847 it reached 73,444; in 1848, 58,014; in 1849, 60,062; and in 1850, 63,168. This disturbance in the ordinary tide of emigration has been attributed to the political revolutions attempted in 1848 and 1849. The increase continued till 1854, when the German emigrants reached the number of 206,054. In discussing the causes of this remarkable exodus Frederick Kapp, for many years a commissioner of emigration, says in his work on "Immigration": "The *coup d'état* of Louis Napoleon closed for all Europe the revolutionary era opened in 1848. In the three years preceding that event, the issue of the struggle of the people against political oppression had remained doubtful. But the second of December, 1851, having decided the success of the oppressors for a long time to come, the majority of those who felt dissatisfied with the reactionary *régime* left their homes. The fact that the largest number of Germans ever landed in one year in the United States came in 1854, showed the complete darkening of the political horizon at that time. The apprehension of a new continental war, which actually broke out a year later in the Crimea, also hastened the steps of those who sought refuge in this country. People of the well-to-do classes, who had months and years to wait before they could sell their property, helped to swell the tide to its extraordinary proportions." From the beginning of 1845 to the close of 1854 the number of Germans arriving in the United States was 1,226,392, of whom 452,943 came in the first and 773,449 in the last five years. In 1866 and 1867 the tide of German emigration again began to swell, "in consequence," according to Mr. Kapp, "of the emigration of men liable to military service from the new provinces annexed to Prussia in 1866, and of families dissatisfied with the new order of things." In 1872 it reached the unprecedented magnitude, except in 1854, of 155,595.

The extent of the emigration to the United States, however, is not governed by political events, failure of crops, commercial and industrial crises, &c., acting in Europe alone, but also by the same causes operating in this country. The effects of the great financial crisis of 1837 are indicated in the falling off of the total immigration from 79,340 in that year to 38,914 in the following. And so the commercial crisis of 1857 was followed in the two ensuing years by a smaller immigration than that of any year since 1845; while during the first two years of the civil war (1861 and 1862), the number of aliens arriving was less than that of any year since 1844. Since the close of the war there has been a marked increase. The arrivals amounted to 449,483 in 1872, being more than in any preceding year, and 437,004 in 1873. The northern and western states, chiefly the latter, have been the chosen destination of the great majority of emigrants to the United States. Prior to the civil war there was very little emigration to those states in which slavery existed, except Missouri. Since the war great efforts have been made by the southern and southwestern states to encourage emigrants to settle there, but with only partial success as yet. In many of these states bureaus of emigration have been established or commissioners appointed, for the purpose of preparing reports showing the inducements offered to emigrants. This information is published in various languages and gratuitously distributed in the United States and in Europe. The United States bureau of statistics also publishes information for emigrants relative to the demand and compensation for labor in the several states, the cost of living, the price and rent of land, staple products, market facilities, the cost of farm stock, and such other practical information as the emigrant most needs.—The contribution made by emigration to the population and wealth of the United States has been in the highest degree valuable and important. Its extent, however, is determined only by computation, and different authorities have reached different results. According to Mr. Kapp, who followed the estimate of Mr. Schade that the natural rate of increase in the native population of the United States, exclusive of slaves, had been 1.38 per cent., that population, including white and free colored, would have been 8,435,882 in 1860, and 9,675,041 in 1870; whereas the total white and free colored population, including the foreign element, was 27,489,662 in 1860, while the white population alone in 1870 was 33,589,377. According to this calculation, more than 24,000,000 of the population in 1870 was of foreign extraction. Dr. Jarvis, however, has shown that this proportion is entirely too great, owing in part to the fact that the census reports of the number of births and deaths on which the calculation is based are erroneous. According to the federal census, the number of foreign-born living in the

United States was 2,244,602 in 1850, 4,138,697 in 1860, and 5,567,229 in 1870. In the last named year statistics concerning the nativity of parents were collected for the first time, and show that there were 10,892,015 persons having one or both parents foreign, 10,521,233 a foreign father, 10,105,627 a foreign mother, and 9,734,845 both parents foreign. There were therefore 1,157,170 persons of mixed (half American and half foreign) parentage. In measuring the increase of the foreign element, Dr. Jarvis assumes that only one half (578,585) of this number should be added. Deducting this from the census statement, 10,313,430 remain as the surviving number of foreigners and their children of the first generation, as reported by the census of 1870. This, however, does not include the children of the second and third generations, the number of whom Dr. Jarvis determines at 400,000, making the total foreign element in 1870, 10,813,430; American, 22,775,947; aggregate white population, 33,589,377. The census reports the total number of surviving foreigners in 1870 and the total of their children born in the United States of entire and half foreign parentage, but gives no indication of the nationality or race of these children. The distribution of the entire foreign

element into the chief nationalities has been computed by Dr. Jarvis as follows:

NATIONALITY.	Born in foreign countries.	Their children born in U. S.	Total.
Irish.....	1,555,527	1,775,012	3,680,539
German.....	1,690,410	1,616,795	3,807,205
British.....	765,927	731,712	1,496,739
Scandinavian.....	235,791	225,392	467,183
All others.....	1,017,974	972,575	1,990,049
Aggregate.....	5,567,229	5,324,756	10,592,015

According to the report of the United States bureau of statistics, 9,058,141 aliens had arrived in the United States from the foundation of the government to Jan. 1, 1874, of whom 250,000 were estimated to have come prior to 1819. Deducting $1\frac{1}{2}$ per cent. for those not intending to remain, the total number of aliens permanently added to the population to the close of 1873 was 8,907,172. Dr. Jarvis has determined the number of foreigners arriving and of those surviving in the United States at decennial periods since 1790. These results are exhibited in the following statement, and it will be seen that the variance is slight from the census returns of foreigners in 1850, 1860, and 1870:

EMIGRANTS ARRIVING IN DECENNIAL PERIODS AND SURVIVING AT THEIR CLOSE.

ARRIVED.		SURVIVING IN							
Period.	Number.	1800.	1810.	1820.	1830.	1840.	1850.	1860.	1870.
1790-1800.....	50,000	44,282	34,732	27,241	21,364	16,775	13,135	10,272	8,179
1800-1810.....	70,000	61,993	45,623	38,137	29,912	23,796	18,237	14,600
1810-1820.....	114,000	100,961	79,137	62,109	49,409	37,868	30,313
1820-1830.....	500,000	177,141	138,940	110,578	84,704	67,510
1830-1840.....	682,112	611,486	486,450	372,829	285,499
1840-1850.....	1,711,161	1,552,709	1,150,086	952,655
1850-1860.....	2,766,495	2,421,944	1,938,732
1860-1870.....	2,424,390	2,253,548
1790-1870.....	8,018,158	44,282	96,725	176,825	315,880	559,202	2,236,217	4,185,890	5,564,873
Census.....	2,244,602	4,188,697	5,567,229
Variance.....	8,885	2,807	2,581

In reaching the above results, the numbers of the survivors of those who arrived in each decade are calculated at the annual rate of 2.4 per cent. mortality and .976 per cent. surviving for the periods 1790 to 1850, 2.625 per cent. mortality for the period 1850 to 1860, and 2.2 per cent. mortality for the decade 1860 to 1870. This is a very high rate of mortality, especially when it is considered that among the emigrants are included only a small portion of those in the perilous periods of life, the very young and the aged, but that they are chiefly in the healthy ages, when the death rate is low. This, however, may be explained by the fact that they are mostly of the poor, whose death rate is everywhere greater than that of the comfortable classes; and that a large proportion of them are Irish, whose vitality is very low. It would be important to know the capital value of immigration to the United States, and the addition thus made to

the national wealth; but this result can only be reached by a computation which will be but approximately accurate. In 1856 the commissioners of emigration in New York examined every emigrant as to the amount of his means, and it was ascertained that the average cash of each of the 142,342 arriving that year was \$68 08. This amount, however, was thought to be much below the actual average, since it subsequently appeared that many emigrants, not understanding the object of this inquiry, were careful not to report the full amount of their means. Mr. Kapp estimated the average amount of money brought by each emigrant at \$100, and other personal property at \$50; total, \$150. This estimate, however, is believed by many to be far beyond the facts. Dr. Young estimates the average amount brought by each at \$80. Assuming that the 422,545 aliens who arrived in the United States in 1873 with the inten-

tion of remaining brought an average of \$80 each, it will be seen that the immigration of that year added \$33,803,600 to the wealth of the country. Applying the same calculation to the total number of aliens arriving with the intention of remaining from the formation of the government to the beginning of 1874, and the result is about \$712,000,000 as the total amount contributed by immigration to the wealth of the country since its origin. In the above computation only the money value of the emigrant is considered, but the economic value of each, arising from the addition to the industrial and intellectual resources of the country, is still greater. Mr. Kapp, taking the estimate of the distinguished German statistician, Dr. Engel of Berlin, that it costs 750 thalers to produce a manual laborer in Germany, and assuming that about double this amount is the cost of an unskilled laborer in America, calculates that the capital value of each male emigrant is \$1,500, and of each female \$750, making the average for every person of either sex \$1,125. Dr. Young, however, considers this estimate to be too high, and makes the average capital value of each immigrant \$800. At this rate the emigration to the United States in 1873 added about \$338,000,000 to the national wealth, while the increase from this source since the formation of the government is about \$7,125,700,000. The uncertainty of such computations, however, is made still greater by the fact that no allowance is made for unfortunates, paupers, and criminals, who are a charge to the community. These classes of foreigners in 1870 numbered nearly 50,000, as appears by the following statement from the census, showing the total of each class national and foreign in the United States:

CLASSES.	Aggregate.	Born in United States.	Born in Foreign Countries.
Blind.....	20,320	17,043	3,277
Deaf and dumb.....	16,205	14,869	1,336
Insane.....	37,382	26,161	11,221
Idiotic.....	24,527	22,882	1,645
Paupers receiving support June 1, 1870.....	76,737	53,939	22,798
Number of persons in prison June 1, 1870.....	32,901	24,173	8,728
Total.....	208,072	159,067	49,005

—The most extensive European emigration has been from Great Britain and Ireland. According to the report of the land and emigration commissioners, 7,561,285 persons emigrated from the United Kingdom between 1815 and 1873, the principal points of destination being the North American colonies, the United States, and the Australian colonies. The largest proportion of these have been from Ireland. Thus the official reports of the United States show that of the 4,319,048 immigrants from the British isles between 1820 and the beginning of 1874, 2,907,565 were from Ireland, 719,776 from England, and 124,331 from Scotland.

Prior to 1815 the emigration from the United Kingdom was unimportant. Up to 1835 the main stream was toward the North American colonies; but since that year the great body of British emigration has been to the United States. Including the foreign emigration passing through the country, which has been considerable since 1864, and constituted 26 per cent. in 1872, it has been:

YEARS.	To the North American Colonies.	To the United States.	To the Australian Colonies and New Zealand.	To other places.	Total.

Notwithstanding this great exodus, the population of the United Kingdom increased from 18,627,476 in 1811 to 31,817,108 in 1871. The increase has been steady and constant in England, Wales, and Scotland; but in Ireland there has been a remarkable decrease. In 1841 the population of Ireland was 8,175,124; and in

1851, owing chiefly to the great exodus following the famine of 1846, it had decreased to 6,551,970. In 1861 it was 5,792,055, and in 1871 5,402,759, or more than half a million (535,097) less than it was in 1811. In Great Britain protection is extended by the government to emigrants, especially those destined to the British possessions. Emigration is regulated to a considerable extent by the government, acting through the land and emigration commissioners. Acts have been passed at various times for regulating the number of passengers in each ship and providing for their proper accommodation on board, and for protecting them from the numerous frauds to which they are exposed. To enforce the provisions of these acts, and generally to protect the interests of emigrants, government agents are stationed at the principal ports of embarkation, and at the chief colonial ports to which emigration is directed.—The German emigration is chiefly to the United States, and its principal points of departure are the ports of Hamburg and Bremen. As early as 1819 efforts were made in Brazil to attract emigration from Germany and Switzerland, but the treatment of the emigrants by the large property holders prevented the success of the enterprise. In 1850 an act was passed offering great inducements to colonists, and the immigration of settlers from Europe, particularly Germans and Swiss, has been otherwise encouraged by the government. These efforts have been attended with but partial success, as only about 50,000 persons have settled in the empire, chiefly in the southern provinces. There has been an immigration of some importance during recent years into the Argentine Republic. This amounted for 14 years ending Jan. 1, 1871, to 204,451 persons, who were mostly from Italy, Spain, and France. In order to encourage immigration, the government of Buenos Ayres in 1873 offered a premium of \$50 each to the first 100,000 immigrants between the ages of 12 and 45, to be paid at the expiration of 18 months after arrival.—Formerly the doctrine was held by Great Britain and other European powers that a subject could not throw off his allegiance by emigrating therefrom; and whether he became a naturalized citizen of another country or not, his own still retained its claim upon him. Treaties, however, have been recently concluded between the United States and Great Britain, Sweden and Norway, Denmark, Belgium, the late North German Confederation, Austria, Hungary, Baden, Bavaria, Hesse-Darmstadt, Württemberg, and Mexico, which provide that subjects of these powers who have become naturalized citizens of the United States, and have resided uninterruptedly therein for five years, shall be held to be citizens thereof. The treaties with Belgium and Great Britain do not require a residence of five years within the United States, but recognize citizenship if sooner acquired. It seems to be the opinion of French jurists

that a French subject can at any time by his own act transfer his allegiance to any country which consents to naturalize him. He thus, according to the Code Napoléon, "loses the quality of a Frenchman." Italy, Spain, Norway, and Greece follow substantially the Code Napoléon, and treat nationality as lost by naturalization in a foreign country, or by entering without royal license into its civil or military service. A Russian subject cannot emigrate or become naturalized in a foreign country without the permission of the emperor; if he does so, he commits an offence for which he may be for ever excluded from the Russian dominions. Nor can a subject of the Ottoman empire divest himself of that character without the authority of the imperial government.

EMINENT DOMAIN (in the Roman law, *dominium eminens*), the right of property possessed by a state, which is higher over all the goods and valuables within the state than that of any individual. *Dominus* and *magister* are both translated by the word "master;" but *dominus* means master by the right of property, while *magister* means master by the right of superiority. Hence *dominium* as a law term is quite accurately represented by the word property. The phrase eminent domain means, in practice, the right inherent in any sovereignty of taking possession of any valuable thing, be it real or personal, and using it for a public purpose. Where, in the theory of the law, all property is held by tenure from the sovereign, the exercise of this right may be regarded as only a resumption of that which it originally granted; and all property may be supposed to rest on a title to which the condition was annexed that it might be thus resumed by the original grantor. In this country, as in all other republics, the right of eminent domain rests on the paramount right of the public welfare. Whatever be its ground, it is entirely certain that the right of eminent domain, or the right to take private property for public use, is distinctly asserted and frequently exercised, both by the national government and by that of the several states. One condition is always affixed to it, viz., that the public good requires that private property should thus be taken for public use; and this fact must be ascertained under legislative authority. Another condition is annexed to the exercise of this power by the constitution of the United States, and by that of many states—a condition which is universal in practice, and would doubtless be held to be always implied in law; it is that adequate compensation be made to those from whom the property is taken. The most common instances of the exercise of this power are in the case of lands taken for roads or canals; but it is, we conceive, quite certain that the principle itself is wholly unlimited, and that by virtue of it any property may be taken by the sovereign power from any owner, provided it is required for public use, and compensation is made to the owner from whom the prop-

erty is taken. The taking need not be by the sovereignty itself, but, under legislative authority, may be by corporations or individuals empowered to construct works of public utility; and in several of the United States it has been decided that the construction of mills and manufacturing is so far a matter of public concern as to justify the appropriation of private property under the eminent domain to obtain the requisite water power.

EMIR, or Amir, an Arabic title, meaning a prince or commander. The caliphs had the title of *emir al-mumenin*, commander of the faithful; and the Abbassides toward the latter part of their dynasty named their chief minister *emir al-omra*, prince of the princes. This official presided over the council and commanded the army. About 1588 Amurath III. appointed one of the Druse sheiks emir, with viceregal powers. In Persian *mir* is derived from *emir*, and hence *mirzadé*, descendant of a prince, which has been corrupted to *mirza*.

EMLYN, Thomas, an English clergyman, born in Stamford, May 27, 1663, died July 30, 1743. He was educated at Cambridge, and settled in 1691 in Dublin, where he gained great reputation as a preacher. In 1697 he advanced doctrines at variance with those of his congregation, declaring the Father preëminent over the Son and Spirit, and thus reviving Arianism. The opposition which was excited against him obliged him to leave Ireland, and he published in England a "Vindication of the Worship of the Lord Jesus Christ on Unitarian Principles" (1706). This book brought upon him a prosecution for blasphemy, and he was fined and condemned to a year's imprisonment. He did not pay the fine, but remained in prison two years, and after his release preached to a congregation of his friends in London. Besides his theological works, he wrote "Memoirs of the Life and Sentiments of Dr. Samuel Clarke" (1731).

EMMANUEL, Emanuel, or Immanuel, a Hebrew word signifying "God with us." It is used by Isaiah in a prophecy which according to Matthew was accomplished in Jesus Christ, who is thus divinely recognized as the predicted Messiah, the true Immanuel, or "God with us."

EMMENAGOGUES, drugs used to promote the menstrual function. No drug has the power to do this directly and independently of the efforts of nature. Some medicines, such as aloes and other cathartics, produce a congestion in the neighborhood of the uterus which may be shared by this organ. Local warmth has a similar effect. Savin, tansy, rue, and to a less degree other aromatics, act as general stimulants, and under favorable circumstances assist the natural function. But tonics, and especially iron, are in many cases of much greater use than any of these. The local application of electricity is often of service. The name emmenagogue is in some classifications made to include ergot and other drugs which have no effect upon the secretions of the uterus. Certain emmenagogues are used as abortifacients, but for-

tunately are but little to be relied upon for this purpose. Ergot alone is inefficient as an abortifacient. Tansy and savin are not only dangerous, but frequently fail to produce abortion, even when they destroy the life of the mother. The root of the cotton plant (*gossypium*) has been much used in the southern states for the purpose of regulating and promoting the catamenial discharge, and when properly administered is not without value for this object. Whenever there is local disease of the ovaries or uterus, which disturbs and checks the menstrual function, the best emmenagogue is an appropriate local treatment.

EMMERICH, a town of Prussia, on the right bank of the Rhine, 5 m. N. E. of Cleves; pop. in 1871, 7,817. It is the nearest Prussian town to Holland, on the railway connecting Cologne with Amsterdam, and here the baggage of travellers is inspected by the custom-house officials. The minster is the oldest church in that part of the Rhine country. Woollens, hosiery, linens, hats, and other goods are manufactured, and there is an active shipping trade.

EMMET, a N. county of Michigan, bordering on Lake Michigan and the straits of Mackinaw; area, about 700 sq. m.; pop. in 1870, 1,211. It is indented by numerous bays. The chief productions in 1870 were 4,452 bushels of Indian corn, 5,972 of oats, and 40,730 lbs. of maple sugar. Capital, Little Traverse. (See EMMETT.)

EMMET. I. Robert, an Irish revolutionist, born in Dublin in 1780, hanged in the same city, Sept. 20, 1803. He gained high honors at Trinity college, from which he was ultimately expelled for avowing himself a republican. He joined the association of United Irishmen, whose object was to separate Ireland from Great Britain and to establish an independent republic, and he was implicated in the rebellion of 1798. After the failure of this attempt he escaped to France, returned secretly to Dublin in 1802, reorganized the malcontents, established various depots of powder and fire-arms in different parts of the city, and fixed upon July 23, 1803, as the time to seize the castle and arsenals of Dublin. On the evening of that day he directed the distribution of pikes among the assembled conspirators, to whom he delivered an animated harangue. The insurgent band, marching with cheers into the principal street, and swelling into an immense and furious mob, assassinated Chief Justice Kilwarden, who was passing by in his carriage; but they hesitated to follow their enthusiastic leader to the castle, and dispersed at the first volley from a small party of soldiers. Emmet escaped to the Wicklow mountains. After the failure of the first blow he checked the other movements which had been projected, husbanding his resources in the hope of soon renewing the revolt. He might have evaded the pursuit of the government, but an attachment for Miss Curran, the daughter of the celebrated barrister, induced him to return to Dublin to bid her

farewell before leaving the country. He was tracked, apprehended, tried, and convicted of high treason. He defended his own cause, delivering an address to the judge and jury of remarkable eloquence and pathos, met his fate with courage, and won general admiration for the purity and loftiness of his motives. His fate and that of Miss Curran are subjects of two of the finest of Moore's Irish melodies. **II.**

Thomas Addis, a politician and lawyer, brother of the preceding, born in Cork, April 24, 1764, died in New York, Nov. 14, 1827. He graduated at Trinity college, Dublin, studied medicine at the university of Edinburgh, visited the most celebrated schools of the continent, then selected the legal profession, studied two years at the Temple in London, and was admitted to the bar of Dublin in 1791. He soon became a leader of the association of United Irishmen, and was one of a general committee to superintend all similar associations, having rebellion for their ultimate object. He was arrested with many of his associates in 1798, and was finally conveyed a prisoner to Fort George in Scotland, where he was confined for more than two years. After the treaty of Amiens he was liberated and permitted to withdraw to France, the severest penalties being pronounced against him if he should return to Ireland. His wife obtained permission to join him on condition that she should never again set foot on British soil. From Brussels, where he passed the winter of 1802-'3, he saw his brother Robert embark in the enterprise which led him to the scaffold. He came to America in 1804, rose to eminence in his profession in New York, and was attorney general of that state in 1812. While in prison in Scotland he wrote sketches of Irish history, illustrative especially of the political events in which he had taken part, which were printed in New York in 1807, under the title "Pieces of Irish History." His biography was written by C. G. Haynes (London, 1829), and a monument was erected to him in St. Paul's churchyard, New York. **III.** **John Patten**, an American physician, son of the preceding, born in Dublin, April 8, 1797, died in New York, Aug. 13, 1842. He came with his father and other Irish exiles to the United States, was educated for three years in the military school at West Point, resided one year in Italy, and studied medicine after his return. His delicate health obliging him to seek a milder climate, he removed to Charleston in 1822, and began practice. He was in 1824 elected professor of chemistry and natural history in the university of Virginia, and during several years was a contributor to Silliman's "Journal."

EMMETT, a N. W. county of Iowa, bordering on Minnesota, and intersected by the East and West forks of Des Moines river; area, about 450 sq. m.; pop. in 1870, 1,392. There are several lakes in the county. The chief productions in 1870 were 29,621 bushels of wheat, 12,816 of Indian corn, 27,819 of oats, and 6,948 tons of hay. Capital, Esterville.

EMMETTSBURG, a town of Frederick co., Maryland, about 50 m. N. W. of Baltimore; pop. in 1870, 706. It contains several churches, an academy, an institute for girls under the care of the sisters of charity, and Mount St. Mary's college and theological seminary, a Roman Catholic institution, organized in 1808. In 1871 the college had 26 professors and instructors, 161 students, and a library of 8,000 volumes; the theological department had 4 professors and 25 students.

EMMONS, Nathanael, an American theologian, born in East Haddam, Conn., April 20, 1745, died in Franklin, Mass., Sept. 23, 1840. He graduated at Yale college in 1767, was licensed to preach in 1769, and ordained pastor of the church in Franklin in April, 1773, continuing in the pastorate till 1827. He claimed to be a genuine Calvinist, though differing from the theological views of Calvin in several important respects. Of some of his peculiar speculations, one is, that there is no such thing as holiness or sinfulness except in the exercise of the voluntary affections, so that there is no depravity except in voluntary disobedience; and another, that God is the efficient, producing cause of every act of the human mind, thus making the will of God the source of all sinfulness as well as holiness, while every moral act, he would claim, is at the same time perfectly free and voluntary on the part of man. Dr. Emmons was one of the founders and first president of the Massachusetts missionary society, and one of the editors of the "Massachusetts Missionary Magazine." He guided the studies of some 87 theological students. His writings published in his lifetime were numerous, and his complete works, in 6 vols., edited with a memoir by the Rev. Jacob Ide, were published in Boston in 1842. See also "Memoir of Nathanael Emmons," by Professor Edwards A. Park, D. D. (Andover, 1861).

EMORY. I. John, a bishop of the Methodist Episcopal church, born in Queen Anne's co., Md., April 11, 1789, died in Baltimore co., Dec. 16, 1835. He was admitted to the bar at the age of 19, but soon abandoned the legal profession, and in 1810 joined the Philadelphia conference. During the following ten years he filled important stations in Washington, Philadelphia, Wilmington, and other cities. In 1820 he was chosen the first delegated representative of the Methodist Episcopal church of America to the British Wesleyan conference. From 1824 to 1832 he was book agent and editor of the book concern in New York. In this difficult position he displayed a rare combination of intellectual power and culture with business habits, by which the embarrassments that had surrounded the concern from its organization were entirely removed and a better policy inaugurated. He was the originator of the publishing fund and the founder of the "Methodist Quarterly Review." In 1832 he was elected bishop. In this capacity he was especially active in forwarding the educational interests

of the church, being one of the chief founders of Dickinson college and the originator of a plan designed to aid in the education of the sons of the clergy. Besides contributing nearly every original article in the first two volumes of the "Methodist Quarterly Review," he wrote two pamphlets in reply to Bishop White's "Objections against Personal Assurance by the Holy Spirit;" "The Divinity of Christ vindicated against the Cavils of Mr. John Wright;" "The Defence of our Fathers;" and "The Episcopal Controversy Reviewed." His son published his biography with a collection of his writings (8vo, New York, 1841). **II. Robert**, an American clergyman, son of the preceding, born in Philadelphia, July 29, 1814, died in Baltimore, May 18, 1848. He graduated at Columbia college in 1831, and commenced the study of law. In 1834 he was called to the chair of ancient languages in Dickinson college, resigned his professorship in 1839, and entered the Baltimore conference of the Methodist Episcopal church; but in 1842 he was recalled, as president *pro tem.*, during the absence of President Durbin, upon whose resignation Dr. Emory was chosen his successor. This office he held until the close of his life. Besides a life of his father, he wrote a "History of the Discipline of the Methodist Episcopal Church" (8vo, New York, 1843; revised and brought down to 1856 by the Rev. W. P. Strickland), and an unfinished "Analysis of Butler's Analogy," which was completed by the Rev. George R. Crooks (1856).

EMPEDOCLES, a Greek philosopher, born in Agrigentum, Sicily, flourished about the middle of the 5th century B. C. The son of a rich family, he was instructed by the Pythagoreans, and was acquainted with Parmenides and Anaxagoras. Like his father Meton, the leader of the popular party at Agrigentum, he saved the republic from a dangerous conspiracy, and refused the supreme power. A priest and a poet, a physician and a philosopher, his contemporaries esteemed him as a god; Plato and Aristotle admired him, and Lucretius sang his praises. It is said that he saved the life of a woman in a lethargy from which other physicians were powerless to revive her; and that he blocked up a mountain gorge through which pestilential winds were driving upon Agrigentum, and at another time stopped the raging of the plague by turning two rivers through a morass. His vanity equalled his ability. He appeared in public only in the midst of a retinue of attendants, with a crown upon his head, sandals of brass on his feet, his hair floating over his shoulders, and a branch of laurel in his hand. He proclaimed his divinity himself, and it was recognized throughout Sicily. It was his aim to affect the imagination not less than the reason. In his old age he left Sicily, not, as has been said, to converse with the priests of Egypt and the magi of the East, but to teach philosophy in Greece. He visited Thurium and Athens, sojourned in the Pelopon-

nesus, and read a poem at the Olympic games. His last days were passed in obscurity in the Peloponnesus. Some imagined that he was translated to heaven; others that he was drowned in the sea; that he fell from his chariot; that he was strangled by his own hands; or that he plunged into the crater of Etna, in order by hiding his body to certify his divinity, but that the volcano subsequently belched forth one of his sandals. The works of Empedocles were all in verse, embracing tragedies, epigrams, hymns, and an epic. The most important of them were two didactic poems, one on "Nature," the other on "Purifications," treating of worship and magic, and containing his religious precepts. Fragments only of these remain, but those of the treatise on nature are sufficient to give an idea of the plan of the work. It consists of three books: in the first, after stating the conditions of human knowledge, he treats of the universe in general, of the forces which produce it, and the elements which compose it; in the second, of natural objects, of plants and animals; and in the third, of the gods and divine things, and of the soul and its destiny. A Homeric spirit, as Aristotle calls him, he personifies and deifies everything, and robes himself in symbols and mystery. The doctrine of Empedocles is developed in the "Sophist," the "Meno," and the "Phædo" of Plato, and in the "Soul" and the "Metaphysics" of Aristotle. The best edition of his remains is that by Karsten (Amsterdam, 1838), which is furnished with admirable dissertations.

EMPEROR (Lat. *imperator*, commander), a title bestowed in the Roman republic on chief commanders of great armies, on consuls elect before entering upon their office, and often used by victorious troops to hail on the battle field a successful general. In later times it designated the highest authority in the state. Cæsar, returning from his last campaign, after the victory of Munda (45 B. C.), received it in this sense, but died soon after. Octavianus Augustus, after the battle of Actium (31 B. C.), assumed this now regal title in preference to *rex*, and Rome became an empire. Augustus and his successors took in addition the name of Cæsar, and both the title and the name (*Kaiser*) were afterward adopted by monarchs of other states. When the rule of the Roman empire was divided, the name Cæsar designated the adopted assistant of the emperor, who was himself honored by the title of Augustus. These titles disappeared in the West with the fall of Rome (476), but continued in the eastern or Byzantine empire for nearly ten centuries longer. During the crusades we find also a Nicean and a Trapezuntine empire in the East. But all these eastern states were swept away and replaced by the power of the Turks, whose sultans never officially adopted the title of the vanquished Christian monarchs. This had been restored in the mean while in the West by Charle-

magne, who received the imperial crown from the hands of Leo III. at Rome on Christmas day, 800, and was hailed by the people with shouts of "Life and victory to Carolus Augustus, the God-sent, pious, and great emperor of Rome, the bringer of peace." When the empire of this great Frankish monarch was divided by his grandsons, the title of emperor of Rome was given to the eldest of them, the king of Italy, and his descendants bore it until it was taken (962) by the mightier king of Germany, Otho I. And now began a long series of expeditions to Italy, undertaken by the German monarchs, in order to be crowned in Milan with the iron crown of Lombardy, and in Rome by the pope with that of the Roman empire; a series of struggles between the emperors, claiming the sovereignty of the Roman world according to their title, and the popes, claiming the same as successors of St. Peter; between the worldly and spiritual heads of the Christian nations. German bravery and Italian diplomacy were by turns victorious and vanquished; emperors were humiliated, popes were stripped of their dignity; Germany was distracted and Italy desolated. The reformation struck at the pope, and indirectly at the empire. The German kings, who usually had been elected exclusively from Frankish or German houses, in earlier times by all, but later only by the greatest princes of Germany, who were hence called electors, gave up their Roman imperial pretensions, and were crowned in Germany as emperors of that country. At their coronation, celebrated in Aix-la-Chapelle, Augsburg, Ratisbon, or Frankfort, the emperors were obliged to sign an instrument, called capitulation, containing the conditions under which they were raised to their dignity. They lived in *palatia* set apart for their use (*Pfalzen*), in later times in their hereditary dominions. The wars of the reformation broke the ancient forms and institutions; the imperial dignity became almost hereditary in the house of Austria; the other German states were made nearly independent; Prussia became a kingdom under Frederick I.; and the unity of Germany was virtually destroyed. The wars that followed the French revolution wrought still greater changes, and when Napoleon had assumed the imperial dignity (1804), and founded the Rhenish confederacy, Francis II., who had proclaimed himself emperor of Austria in 1804 (as such Francis I.), in 1806 finally renounced the German imperial title, and what was once the Roman, now the German, empire expired. Its restoration was during the revolutionary period of 1848-'9 the favorite idea of a party in the Frankfort parliament; but the refusal of the king of Prussia to accept the imperial crown made the scheme a failure.—Several other monarchies of Europe had taken the imperial title. Russia assumed it under Peter the Great (1721), and the assumption was in time acknowledged by all the states of Europe. The empire of the French, founded

by Napoleon on the ruins of the republic, perished at Waterloo (1815), but was revived after two revolutions by the nephew of its founder (1852), and was succeeded by a republic, proclaimed Sept. 4, 1870. The empire of Germany was reestablished by the assumption of the title of emperor by King William of Prussia, Jan. 18, 1871. On the American continent several empires have been established, but most of them destroyed by revolutions. That of Mexico under Iturbide (1822) was ephemeral; under Maximilian it lasted from June 12, 1864, to June 19, 1867. That of Brazil is governed constitutionally. That of Hayti, which was nominally constitutional, was overthrown in January, 1859, and replaced by a republic. The Asiatic states of China, Japan, and Anam, and the African Fez and Morocco, are also often called empires.

EMPHYSEMA (Gr. *ἐμφύσημα*, inflation, from *ἐν*, in, and *φύσσω*, to blow), a diseased condition of man and animals, in which gases are developed in or have been introduced into any part of the body; generally restricted to the dilatation of the cells of areolar tissue or of the lungs by atmospheric air. Gaseous collections in serous cavities, or in canals lined with mucous membrane, have received other names. Three kinds are usually described, which may be called surgical or traumatic, spontaneous, and pulmonary emphysema.—Traumatic emphysema, though always subcutaneous in the commencement, is not always accompanied by wound of the skin; it may occur after severe contusions of the chest, or after fracture of the ribs, the air cells of the lungs being ruptured, and in the latter case punctured by the broken bone, with or without external communication. In any of these conditions, if the wound of the lung be small, and especially if it be not in direct connection with an opening in the skin, the respired air, not being able to pass out freely, becomes infiltrated in the areolar or cellular tissue, forming a soft and crepitating swelling, which may extend over a great part of the body; during inspiration the air escapes into the cavity of the chest through the wound in the lung, and during expiration, being compressed between the lung and the thoracic walls, it is forced into the subcutaneous cells, the amount tending to increase at each performance of the respiratory act. Emphysema may arise from any portion of the air passages, and frequently is seen accompanying wounds of the larynx and trachea; if the external wound be extensive, and the opening in the lung or trachea small, this complication is not likely to occur. The ordinary symptoms are painful constriction of the chest at the injured part, and difficulty of breathing, which may become almost insupportable, and even produce death by suffocation. The swelling of emphysema may be distinguished from effusions of fluids under the skin by its crepitation and elasticity, by its not pitting on pressure of the finger, and by the absence of redness, pain, and weight.

After distending the cellular tissue under the skin, the air may penetrate between the muscles, along mucous canals, vessels, and nerves, to the inmost recesses of the organism. The treatment consists in letting out the confined air by minute punctures with a lancet, and preventing its reaccumulation by proper bandages, and in cases of extreme oppression by paracentesis or incision of the thoracic walls; the cure may be hastened by antiphlogistic measures, and by stimulating applications and frictions. In Europe it is not uncommon for persons desirous of securing immunity from military service, and for purposes of mendicancy and deception, to inflate with air various parts of the surface of the body, pretending that their condition is the result of chronic or congenital diseases; the treatment in these cases consists in scarifications, bandages, and tonic frictions. Spontaneous emphysema may occur after exposure to great cold, in certain cases of internal poisoning and of poisonous bites, after copious bleedings and various severe accidents, and in debilitated conditions accompanied by gangrene. The treatment for this is the same as for the preceding variety.—Pulmonary emphysema may be either vesicular or interlobular. In the first the vesicles are enlarged, ruptured, and united, and the lung, when the chest is opened, may be so distended, more especially the upper lobes, as to protrude from its cavity; when only one side is affected it presses upon and displaces the heart and the other lung; such diseased portions are strongly crepitant, part with their contained air with difficulty, and float very lightly on water. In interlobular emphysema the distended vesicles assume an irregular form, sometimes of considerable size, and are situated just under the pleura; and the emphysematous swelling may be made by pressure to move under the serous covering as far as the next lobular division of the organ. Sometimes the enlarged vesicles are not in the subserous tissue, but in the tissue separating the lobules, between which they may descend to a considerable depth. These varieties are usually combined, their symptoms are the same, and the latter is generally considered the consequence of the former, the distention and rupture of the vesicles proceeding to a greater extent. Laennec and Piorry maintained that pulmonary catarrh was one of the principal causes of the dilatation of the vesicles, which, unable to free themselves from the viscid mucus without great effort, of necessity became enlarged. Louis seems to consider that some power of active dilatation is brought into play. Admitting the connection between emphysema and obstructed bronchi, with the first named authors, there is no necessity for making the former a direct consequence of the latter; measured by a pressure gauge, the forced expiratory act has been found one third more powerful than the act of forced inspiration; as Dr. W. T. Gairdner has well observed (in his work on bronchitis), whenever viscid obstructions

are to be removed from the air passages, the air is gradually expelled from the affected part of the lung by expiration, and they become collapsed in proportion to the obstruction. Emphysema is the direct opposite of bronchial collapse, and its indirect consequence; because, whenever a part of the lung is obstructed or collapsed from bronchitis or any other cause, the air during inspiration must rush with greater force and volume into the portions still freely open. Bronchitic accumulation and collapse are most common at the posterior and lower part of the lungs, and emphysema on the free anterior borders; the emphysematous portions are easily inflated from the bronchi, while the collapsed parts are not. Emphysema is, therefore, essentially a mechanical lesion from distention of the air cells, in proportion to which the flow of blood through the ultimate capillaries of the lungs is arrested, causing absorption of their walls, and tension and obliteration of their vessels. In the case of Mr. E. A. Groux, with congenital fissure of the sternum, in the course of prolonged forced expiration, the chest and abdomen became smaller, the veins at the root of the neck swollen, the upper intercostal spaces convex, and the fissure assumed its greatest width; and above the pulsatile cardiac tumor was a protruding mass which percussion showed to be the anterior portion of the upper lobe of the right lung. This can throw little light on the ordinary causes of emphysema, though the cells are doubtless dilated, because the protrusion is evidently due not so much to the obstructed passage of air or blood as to active muscular effort, and to the raising of the whole thoracic contents by the diaphragm and abdominal muscles in a cavity whose bony wall is deficient in front, where of course the free portion of the lung would protrude. Emphysema has been traced to compression of the bronchi by tumors; to the great respiratory efforts required in playing on certain wind instruments, showing the connection between this disease and forced expiration, and as partly exemplified in the above case of Mr. Groux; the disposition to this disease has also been considered hereditary, and doubtless many cases of so-called hereditary phthisis or asthma are due to the vesicular dilatation consequent on spasmodic bronchial contractions. It is found in both sexes, at all ages, and in all constitutions; once developed, it remains during life, sometimes stationary, but generally increasing, with irregular intervals of ease; the dyspnoea is sometimes such that the patient is obliged to sit up in order to breathe; slight causes, as a catarrh, exposure to irritating gases or dust, or vivid emotions, are sufficient to bring on an attack. Examination of the chest will show an enlargement of the affected side at the upper region of the ribs and intercostal spaces. On percussion the chest is very sonorous, and the respiratory sounds feeble, with râles sonorous, dry, or humid, according to the accompanying catarrhal condition, and the

presence or absence of cough. It is a very common disease, generally chronic in its nature, but sometimes acute and speedily fatal. It may be known by the occurrence of dyspnoea, without palpitations, disease of the heart, oedema, or fever, and often without any signs of catarrh. The principles of treatment are to guard against pulmonary congestion by proper depletives, to diminish the frequency of respiration by opium and other sedatives, to strengthen the weakened system by tonics, to relieve the obstructed bronchi by emetics and expectorants, and to avoid all the exciting causes of catarrh and bronchitis, the most frequent originators and aggravators of the disease.

EMPOLI, a town of Italy, in the province and 16 m. S. W. of the city of Florence, on the left bank of the Arno; pop. about 6,500. It is situated in a fertile valley, and is surrounded by walls flanked with towers. The collegiate church, built at the close of the 11th century, contains fine statuary and excellent pictures, including Giotto's "St. Lucia in the Cavern." The adjoining baptistery and the San Stefano and Santa Croce churches contain likewise several notable paintings. The principal manufactures are cotton, leather, glass, beaver hats, earthen vases, and the so-called Tuscan straw bonnets, the straw being a local product.

EMS, a river of N. W. Prussia, rising in the province of Westphalia, near the S. E. extremity of the Teutoburg forest, on the confines of Lippe-Deimold. It flows first S. W. and then N. W. through Westphalia, and finally N. through Hanover, until it empties through the Dollart estuary into the North sea near the town of Emden and the boundary of Holland. Length of course, about 200 m. It is navigable for vessels of 200 tons to a distance of about 14 m. from its mouth; for small vessels as far as the town of Rheine, about 75 m. from the sea, and a few miles S. of the Hanoverian boundary. Its chief affluents are the Hopster-Aa, Haase, and Leda on the right, and the Werse on the left. The Ems enters the estuary of Dollart by four streams, or "gats," separated by islands, the chief of which is that of Borkum.

EMS, a market town and watering place of Prussia, province of Hesse-Nassau, in the valley of the Lahn, 7 m. S. E. of Coblenz; pop. in 1871, 5,438. It is one of the most famous resorts of Germany, its waters being used with great effect, especially against chronic nervous diseases, both for bathing and drinking. On July 13, 1870, the famous interview between King William of Prussia and the French ambassador Benedetti took place here, which was followed by the declaration of war by France.

EMSER, Hieronymus, a German theologian, born in Ulm, March 26, 1477, died Nov. 8, 1527. In 1502 he became professor at the university of Erfurt, and in 1504 established himself at Leipsic, where he lectured at the university, and in the year following Duke George of Saxony made him his secretary. With Luther and the theologians of Wittenberg generally he

was on good terms until the disputation of Leipsic in 1519, from which time he made, in union with Dr. Eck, incessant endeavors to oppose the increasing influence of Luther and the progress of Protestantism. He attacked the German translation of the Bible by Luther as erroneous, whereupon it was forbidden in ducal Saxony by Duke George. Emser then himself published a German translation of the New Testament, made from the Vulgate (Dresden, 1527). He also wrote *Vita S. Bennonis*.

EMU (*dromaius Novæ Hollandiæ*, Latham), a bird closely allied to the cassowary, a native of Australia and the adjacent islands. The emu differs from the cassowary in its broader bill, in its head covered with feathers above, and in its smaller and more obtuse claws; as in the latter, the cheeks and sides of the neck are naked, the legs long and robust and protected by strong scales, and the wings and tail not

Emu (*Dromaius Novæ Hollandiæ*).

apparent; the middle toe is the longest, the inner the shortest. This bird was named emu by the English colonists, who confounded it with the cassowary or emu of the Moluccas; to distinguish them, ornithologists call the present bird the New Holland emu. There is only one species of the genus, living in the eucalyptus and casuarina forests in the Australian islands. Its length is about 7 ft.; its plumage is thick, and of a brownish color. The feathers are remarkable from their two central stems being united at the base, bearing simple barbs, and sometimes very short barbules. The form is thick and heavy, the back arched, the denuded neck of a violet color, and the feathers on the head are few, simple, and hair-like. The emu presents the closest analogy to the ostrich in its anatomical structure; a wide membranous sac is formed below the crop by a dilatation of the oesophagus, which ends in a slightly developed gizzard; the intestinal canal is about 16 ft. long; the windpipe is very long, and at its 52d ring opens into an immense muscular sac, whose

use is not well ascertained; according to Wagner, the bones of the wrist are wanting in this bird. The natives of New South Wales call the emu *parembang*. * It is timid, runs with great rapidity, and is very rarely taken; it was once common in the neighborhood of Sydney, but civilization has driven it beyond the Blue mountains. It prefers open shrubby places and sandy plains. When pursued it takes readily to the water, and swims with its body mostly submerged. It feeds on fruits, berries, roots, and various herbs. The female lays six or seven eggs, in a slight hollow scratched in the earth; the male hatches the eggs, and takes care of the brood until they can provide for themselves; the young are grayish with four bands of bright red. The flesh is eaten by the natives, and is said to have the taste of beef.

ENALIOSAURIANS (Gr. *ἐνάλιος*, marine, and *σαῦρος*, a lizard), an order of fossil marine reptiles, found in the liassic, triassic, and cretaceous epochs. They unite characters which appear at first sight incompatible, having the vertebrae of fishes, the teeth of crocodilians, the body of lizards, the paddles of cetaceans or marine turtles, and some have a long snake-like neck. Many of these aquatic saurians attained a large size, and from their voracity must have been the terror of the waters of the secondary epoch, after the disappearance of the great sauroid fishes of the carboniferous period. Pictet considers them as coming nearest to the saurians, though so different from any existing types as to require the establishment of a new order, whose principal characters are biconcave vertebrae, wider than long, with laminae feebly united to the bodies; conical teeth, without cavity at their base, implanted in short deep-seated alveoli; and four short, flattened limbs, whose fingers are formed by discoidal bones disposed like those of cetaceans. They have been divided into two groups, whose characters correspond also to their geological position. The ichthyosaurians (including the *ichthyosaurus* and *plesiosaurus*) have well developed crania, with small fossæ and cavities; these have been found in the Jurassic and cretaceous strata. The other group, the simosaurians (including *nothosaurus*, *simosaurus*, &c.), have the cranium with very large temporal fossæ and orbital and nasal cavities; they are found only in the triassic strata. The first two genera are the best known, and the most common in the strata of England and Germany; the *ichthyosaurus* must have attained a length of 25 ft., and the *plesiosaurus* of more than 12, and both presented forms most unlike those of any existing animals, though admirably adapted to the circumstances in which they lived. (See **ICHTHYOSAURUS**, and **PLESIOSAURUS**.)

ENAMELLING, the art of applying a coating of vitreous substance called enamel to a surface of glass or of metal, and causing it to adhere by fusion. In its homeliest application it is a sort of glazing, and as applied by modern methods to ornament and protect surfaces of

cast or wrought iron, it may be considered simply a process of japanning. The facility with which colors might be introduced in vitreous compounds or applied to them, and become fixed by a subsequent fusion or baking, made the art in early times exceedingly popular, and in the middle ages it attained a higher rank even than it now holds, as one of the fine arts. The ancient Persians and Arabians appear to have practised it upon earthenware and porcelain; and the mode of coloring this ware at the present day is properly a process of enamelling. Articles of pottery enamelled in colors are found among the ruins of ancient Thebes, and in many of the cities of Egypt are buildings constructed of enamelled bricks taken from the ruins of older cities. Wilkinson says: "It has been questioned if the Egyptians understood the art of enamelling upon gold or silver, but we might infer it from an expression of Pliny, who says, 'The Egyptians paint their silver vases, representing Anubis upon them, the silver being painted and not engraved;' and M. Dubois had in his possession a specimen of Egyptian enamel." From the Egyptians the art is supposed to have passed to the Greeks, and afterward to the Romans. Brongniart, however, in his *Traité des arts céramiques*, traces its introduction into Italy from the Balearic isles by the Spaniards, who derived the art from the Arabs. The Romans introduced it into Great Britain, as appears from various enamelled trinkets that have been dug up there with other vestiges of the Roman conquerors. That the Saxons practised the art appears from an enamelled jewel found in Somersetsshire, and preserved at Oxford, which according to its inscription was made by direction of the great Alfred. The gold cup given by King John to the corporation of Lynn in Norfolk shows, by the colored enamelled dresses of the figures with which it is embellished, that the Normans also practised the art. Among the Gauls enamelling upon metallic surfaces is understood to have been in use in the 3d century. As practised upon earthenware in the style called by the French *faïence commune ou émaillée*, and by the Italians majolica ware, it was carried to great perfection in the 16th century at Castel Durante and at Florence by the brothers Fontana d'Urbino. Other Italian cities adopted the art, and Faenza became famous for the works of Guido Selvaggio. The high style of art attained hardly outlived the artists who perfected it, and from 1560 it gradually deteriorated. Bernard Palissy, by practice of 25 years directed to the production of a cup like one of great beauty shown to him, sought to introduce the art in France, and his works became very famous, but his method died with him. His productions were interesting from being true copies of natural objects, in relief, and colored with exact faithfulness. Of late years the art has been revived in France, chiefly through the skill of Brongniart; and in Berlin also beautiful work of the

kind has been executed by Feilner.—Painting in enamel, as practised upon plates of gold and copper, can hardly be regarded as applied to works of high art until the 17th century. Jean Toutin, a goldsmith at Châteaudun, appears about the year 1630 to have first made enamels of fine opaque colors, and applied them to portraits and historical subjects. Other artists profited by his instructions, and several miniature painters attained great distinction in this branch. The art afterward fell into disuse, and was only applied to ornamenting watch cases and rings. In the early part of the present century it reappeared in some fine portraits by Augustin, and various French and English artists have since executed many portraits in this style, distinguished for the brilliancy of their colors, and the more valuable for their permanence. A piece of five inches in its longest dimensions was considered the largest that could be undertaken with safety; for with the increase of size the liability of injury to the enamel by cracking, and to the plate by swelling and blistering in the several processes of baking, rapidly increased; but by backing the metallic plate with one of porcelain, the work is now executed in pieces even 18 inches long by nearly as great a breadth. The process is usually conducted as follows: The plate is coated on both sides with white enamel, and on this the design is lightly sketched with a pencil. The colors, finely ground and mixed with oil of spike, are then laid on as in miniature painting. By gentle heat the oil is evaporated, and in an enameller's fire the plate is next made red-hot to incorporate the colors with the enamel. The painting may then be retouched, and the colors again be burned in, and this may be repeated several times. But the greatest accuracy in the first drawing and coloring is essential for a perfect picture. In this department may be consulted the work of Count de Laborde, *Notice des émaux exposés dans les galeries du Louvre*.—In the ordinary processes of enamelling, the enamels used for the ground are opaque, and must bear a higher degree of heat without fusing than the colored enamels, which are afterward melted into them. They are made after a great variety of recipes, according to their uses. All those designed for metallic surfaces have a transparent base, which is rendered opaque by the substitution of combined oxide of lead and oxide of tin, in the place of the oxide of lead used as one of its ingredients. Five different mixtures of the two oxides are in use, the proportions varying from $3\frac{1}{2}$ parts of lead and 1 of tin to 7 parts of lead and 1 of tin. The two metals are melted together, and the combined oxide is removed as fast as it appears upon the surface. When the oxidation is as thoroughly effected as practicable, the product is well washed to remove any particles of metal that may have escaped oxidation, as these would greatly impair the quality of the enamel; for the same

reason it is essential that the metals themselves should be absolutely pure. One or other of the mixtures of oxides obtained by the method described is next melted with proper quantities of silica, saltpetre, and a little borax; the last gives greater fusibility as its proportion is increased, and no more is used when the enamel is to be applied upon copper or silver than upon gold. The plates are sometimes chemically acted on by the enamel, and if the gold of the gold plates is alloyed with too much copper, the appearance of the enamel is injured. An excellent enamel is prepared by mixing 30 parts of saltpetre, 90 of silica, and 250 of litharge; after fusion it is white, and may be used in taking photographs without collodion—gum, honey, and bichromate of potash being used instead. For making colored enamels, either the opaque or transparent enamel serves as a base, and with it is melted a suitable proportion of some metallic oxide as a coloring matter; for a blue enamel, the opaque is used with oxide of cobalt; for a green, oxide of chromium, or binocide of copper; for a violet, peroxide of manganese; for a yellow, chloride of silver; for a purple, purple of Cassius; and for a black, the transparent enamel is used with mixed oxides of copper, cobalt, and manganese. The different enamels, being prepared beforehand, are crushed to powder when wanted for use, and then kept at hand under water in vessels well covered to protect them from all impurities. The metallic surfaces to be coated are cleaned by boiling in an alkaline solution, and are then washed with pure water. The copper alloy in gold may be dissolved from the surface by boiling in a strong solution of 40 parts of saltpetre, 25 of alum, and 35 of common salt.—In the manufacture of enamelled earthenware, the white enamel is prepared by melting 100 lbs. of lead with 15 to 50 lbs. of tin, and adding to the oxides thus obtained the same weight of quartz sand, and about 30 lbs. of common salt. The whole being well rubbed together is melted; and though it may appear dark, it becomes white when reduced to powder and baked upon the utensils. The proportions of the materials employed are very variable, and other ingredients are often introduced, particularly oxide of manganese, the effect of which in small quantity is to yield its oxygen to any carbonaceous impurities that may be present, and remove these in the form of carbonic acid. The colored enamels are applied by painting them when finely ground, and mixed with some vegetable oil, upon the white enamel, either before or after this has been once heated, and then baking them in. The ovens for metallic articles are muffles made to slide closely into the furnace, and furnished with a small aperture through which the progress of the operation may be observed.—The enamelling of cast-iron cooking utensils was practised at the close of the last century, and a number of different mixtures have since

been in use. The use of lead must be carefully avoided in articles of this kind. Vessels of wrought iron are also treated by the same process; and iron pipe for conveying water is advantageously protected by a clean silicious enamel not liable to affect the purity of the water.—The process employed for many years by the Messrs. Clarke of England consisted in the use of the following composition and method: 100 lbs. of calcined ground flints and 50 lbs. of borax calcined and finely ground, to be mixed, fused, and gradually cooled. Of this, 40 lbs. are mixed with 5 lbs. of potters' clay, and ground in water to a pasty mass. The vessel, first thoroughly cleaned, is lined with a coating of this about one sixth of an inch thick, and left for it to harden in a warm room. A new coating is next added, prepared from 125 lbs. of white glass without lead, 25 lbs. of borax, 20 lbs. of soda in crystals which have been pulverized and fused together, ground, cooled in water, and dried. To 45 lbs. of this 1 lb. of soda is added, the whole mixed in hot water, dried and pounded. A portion of it is sifted over the other coating while it is still moist, and dried in a stove at the temperature of boiling water. The vessel is then heated in a stove or muffle till the glaze fuses. It is taken out, more glaze powder is dusted on the glaze already in fusion, and it is again subjected to heat. The *Polytechnisches Centralblatt* for 1872 recommends the following enamel for copper cooking vessels: 12 parts of white fluor spar, 12 of gypsum, and 1 of borax, finely powdered, and fused in a crucible; when cold the mass is again pulverized, and made into a paste with water, laid upon the metal, and fused. Small articles of enamel, as little toys imitating the figures of birds, &c., and also artificial eyes, are made by melting with the table blowpipe rods or tubes of enamel prepared for this purpose, and shaping them by hand, just as the glass blower works with tubes and rods of glass.—Enamelling of slates to imitate marble and malachite was introduced in London by Mr. G. E. Magnus. The art was first practised in the United States at Boston, and slates from Wales were imported for this purpose. Subsequently the slates of the Lehigh river were applied to this use in Lehigh co., Pa., and were also sent to Philadelphia to be there enamelled. In Vermont the business is now carried on at West Castleton, where are extensive quarries of slate, and an establishment of the same kind is in operation in New York. A great variety of useful articles are produced, among which the most important are billiard tables, mantels, tubs for bathing, sinks, &c. The slates are sawed to proper shape, planed to uniform thickness, and rubbed smooth with polishing stones. The ground color adapted to the marble it is designed to imitate is then laid on, and after this the variegated colors. The slab is then placed in an oven heated to 200°, and allowed to remain over night. In the morning

after cooling it receives a coat of varnish, and is returned to the oven till the next day. Other heatings and varnishings alternately succeed, with rubbing with pumice stone; and a final polishing with pumice stone, rotten stone, and the hand completes the process.

ENCAUSTIC (Gr. ἐν, in, and καυστικός, burning), a term applied to the method of fixing colors upon objects by burning them in. Enamelling in colors is an encaustic process. The word is most commonly used in its application to an ancient method of painting, in which wax was employed with the colors, and a coating of the same material was finally applied to the picture to preserve it from the action of the atmosphere and light. In modern use a peculiar kind of tiles are called encaustic; and by the French the same epithet is applied to preparations of wax used for polishing and protecting the surface of wood. The little that is known of the ancient art of encaustic painting is derived from the mention made of it by Pliny ("Natural History," lib. xxxv. ch. xi.), Marcianus (lib. xvii.), and Julius Paulus (lib. vii. *et seq.*). M. Bachelier, author of a treatise *De l'histoire et du secret de la peinture en cire*, produced a picture in wax in 1749. In 1829 M. de Montabert, in his *Traité de tous les genres de peinture*, favorably noticed the process, and M. Durozier of Paris soon after announced that he had perfectly succeeded with the method given by Montabert. The ancient methods appear to have consisted in the use of wax crayons, in which the colors were embodied, and which were used upon a heated surface, the outline of the picture having been first traced. The whole was afterward covered with a varnish of wax melted in and polished. The method of Count Caylus consisted of rubbing and melting wax into the canvas or panel, then coating the surface with Spanish white, and painting upon this with water colors. By warming the picture the colors are absorbed into the wax, and thus protected. Mr. J. H. Muntz recommends waxing only one side of the canvas, painting on the other in water colors, and then melting the wax through to fix them.—**ENCAUSTIC TILES** consist of a body of red clay, faced with a finer clay, which bears the ornamental pattern, and strengthened at the base with a thin layer of a clay different from the body, which prevents warping. The clay of the body is exposed to the weather for six months or more, and is afterward thoroughly worked over and tempered, and mixed with other substances, and at last evaporated at the slip-kiln. From a cubical block of this, formed in the usual method by slapping, a square slab is cut off with a wire, upon which slab the facing of finer clay colored to the desired tint is batted out and slapped down; a backing is then applied in the same way to the other side of the tile. It is then covered with a piece of felt, and put into a box press; a plaster of Paris slab containing the pattern in relief is then brought down upon the face of the tile,

and the design is impressed into the soft tinted clay. The hollows thus formed are filled with a semi-fluid clay of a rich or deep color poured into them and over the whole surface of the tile. In 24 hours this has become hard enough to admit of the surplus clay being removed, which is done by placing the tile, still in the box, upon a horizontal wheel, and as it revolves applying a knife or scraper entirely across, so as to rest upon the edges of the box. The surface is thus cut down so as to expose the pattern and the ground. The defects are removed with a knife, and the edges after being square are rounded off with sand paper. The tiles are kept for a week in a warm room called the greenhouse, and the drying is completed in another called the hothouse. They are then baked like other articles of pottery, except that double the ordinary time is given to the process, and the oven is left six days to cool before the tiles are taken out. They contract in baking from one eighth to one sixteenth of their dimensions. The process is supposed to be nearly the same as that employed in the middle ages in France and England in making pavements for churches, and also for the beautiful pottery called Henry II.'s ware, peculiar to France in the 16th century.—The French apply the term *encaustic* to preparations of wax used for covering furniture and floors, which are then polished by friction.

ENCKE, Johann Franz, a German astronomer, born in Hamburg, Sept. 23, 1791, died in Spandau, Aug. 26, 1865. He studied under Gauss at the university of Göttingen, served in the Hanseatic legion against Napoleon in 1813-'14, and in 1815 entered the Prussian military service, but afterward accepted a situation in the observatory of Seeberg near Gotha. In 1825 he was appointed director of the royal observatory at Berlin. He wrote many valuable memoirs on astronomical subjects, of which the most important are the treatises published in the *Astronomische Nachrichten*, at Berlin, in 1831 and 1832, upon the comet then called by the name of Pons, the astronomer of Marseilles, who discovered it in November, 1818, but now known as Encke's comet. After its discovery Encke diligently applied himself to the determination of its orbit. Making use of the methods of Gauss, as explained in his work *Theoria Motus Corporum Cælestium*, of calculating an orbit assumed to be elliptical, he showed that its period of recurrence must be about $3\frac{1}{4}$ years, and that it was probably the same comet observed by Méchain in 1786, by Caroline Herschel in 1795, and by Pons in 1805. He calculated the effects of the perturbations it would experience from the planetary bodies, especially from Jupiter, and predicted its return in 1822, though it would probably not be visible in Europe. On June 3 of that year it was discovered at the observatory of Sir Thomas Brisbane, governor of New South Wales. Encke predicted its return in 1825, and with each reappearance as predicted more

elements were afforded for computing its exact orbit. It appeared again Oct. 30, 1828, and he was able to fix its orbit as within that of Jupiter, its greatest distance from the sun being four times the earth's distance, and its least distance but one third that of the earth, and its period of revolution $3\cdot29$ years. By comparison of the times of its earlier and later apparitions, Encke was afterward led to detect a gradual acceleration of its movement, amounting to about $2\frac{1}{2}$ hours on each revolution. This secular acceleration, never before recognized in the movement of any other celestial body, Encke ascribed to a resisting medium, which sensibly affects a body of the extreme rarity of this comet, which is transparent to its centre, but has no perceptible effect upon the denser planetary bodies. Resistance shortens the time of the revolution by giving greater effect to the attraction of the sun, which then draws the body more forcibly toward itself, lessening the major axis of the ellipse, and thus its orbit of revolution. In investigating the perturbing effects of the planets upon this comet, of Jupiter in its aphelion, and of Mercury in its perihelion, Encke was led to suspect that the mass of the former had been greatly underrated (a fact afterward established by Prof. Airy); and in 1838 he proved that Lagrange had ascribed nearly three times too great a bulk to Mercury. Encke's explanation of the cause of the acceleration is not universally accepted, although the fact itself is not questioned. Bessel particularly opposed the explanation; by the English astronomers it is more favorably received. Besides these investigations, Encke improved the theory of Vesta, and published a new method of computing perturbations, especially for orbits considerably elliptical. The planet Neptune was discovered at his observatory by Galle, his assistant. From 1830 Encke annually published the *Astronomisches Jahrbuch*, and from 1840 *Astronomische Beobachtungen auf der Sternwarte zu Berlin*. In 1845 he published dissertations *De Formulæ Dioptriciis*; and in 1846 a treatise *Ueber das Verhältniss der Astronomie zu den anderen Wissenschaften*. In the autumn of 1863 he resigned his office.

ENCRINITE (Gr. *κρίνον*, a lily), a fossil genus of the order of crinoids, of the class echinoderms. It appeared among the earliest forms of animal life, its remains being preserved in the rocks of the Silurian period. In succeeding formations, nearly to the lias, they are often so abundant that calcareous strata extending over many miles are in great part made up of them. As described by Miller in his work on the crinoids, the animals of this family are furnished "with a round, oval, or angular column composed of numerous articulating joints, supporting at its summit a series of plates or joints, which form a cup-like body containing the viscera, from whose upper rim proceed five articulated arms, dividing into tentaculated fingers more or less numerous surrounding the aper-

ture of the mouth." In the encrinite the stem is cylindrical; in the kindred genus pentacrinite it is five-sided. The cup-like body is the portion representing the flower of the lily, for which the creature is named. When the tentacula are spread out, the appearance is that of an opened flower; when closed, they represent the bud. The stem served to attach the animal to any bodies in the water, and by the manner of articulation of the plates composing it, it admitted of much motion, swaying back and forth. By this means the head with its tentacula was brought within reach of its prey. The plates of the stem, separating into short cylinders, present the form in which the remains of this animal are most commonly seen. In the marble used for chimney pieces they are often very abundant, the polished surface presenting some of them of a different color from the ground in longitudinal section, some in oblique conical-formed cutting, and some in

ENCRINITES.—1. *Periechocrinus* (*Actinocrinus*). 2. Stem and Pelvis of ditto. 3. Pelvis of *Crotalocrinus* (*Cyathocrinus*). 4. *Dimerocrinus Scosiodactylus*. 5. *D. Decadactylus*.

circular disks, being transverse sections. By the disintegration of the rock the little joints of the fossil stem frequently fall out, and may be gathered in great numbers. Each has a hole through its centre. Dr. Mantell says he has found them preserved in tumuli of the ancient Britons, having evidently been worn as ornaments. In the north of England they are called "wheel stones" and "St. Cuthbert's beads," and were formerly used for rosaries. The encrinites are remarkable for the multiplicity of small calcareous pieces, which make up the various parts of the animal—the stem, the parts that may be called the ten arms, the hands and fingers, and the numerous tentacula which proceeded from them all. These pieces, as enumerated by Parkinson in his "Organic Remains," amount to not less than 26,000, thus showing a complexity of structure equal to any that is met with in the nearest living analogues of these ancient animals. The structure of one

of the fossil pentacrinites (a genus which began to abound as the encrinite disappeared, and has been represented in some of its species down to the present time from the lias, or indeed in a single species from epochs much more remote) has been cited by Dr. Buckland as "showing an equal degree of perfection, and a more elaborate combination of analogous organs than occurs in any other fossil species of more recent date, or in its living representative." The species thus cited is the Briarean pentacrinite of the lias. The *pentacrinus caput medusæ* is almost the only living analogue of the ancient crinoids. (See *CRINOIDEA*.)

ENCYCLOPÆDIA. See CYCLOPÆDIA.

ENDER, Johann Nepomuk, an Austrian painter, born in Vienna, Nov. 3, 1793, died there, March 16, 1854. He studied at the Vienna academy, and when he had hardly attained his majority won its four leading prizes. He accompanied the Hungarian count Szecheni on a journey through Greece and Turkey in 1818. In 1820 he went to Italy, and in Florence and Rome produced a number of works from Biblical and historical subjects. In 1827 he returned to Vienna, after spending a year in Paris. The more noteworthy of his works are his great cartoon of the entry of Christ into Jerusalem; "Judith," exhibited in 1824; and several frescoes of much merit, one of which, the last of his important productions, is in a chapel of the church of St. Stephen in Vienna.

ENDICOTT, John, governor of Massachusetts, born in Dorchester, England, in 1589, died in Boston, Mass., March 15, 1665. He was sent out by the "Massachusetts Company" to carry on the plantation at Naumkeag, or Salem, where he arrived Sept. 6, 1628. In April, 1629, he was chosen governor of "London's plantation;" but in August it was determined to transfer the charter and government of the colony to New England, and Winthrop was appointed governor. In 1636, with Capt. Underhill, Endicott conducted the sanguinary but ineffectual expedition against the Block Island and Pequot Indians. He was deputy governor of the Massachusetts colony from 1641 to 1644, in 1650, and 1654; and was governor in 1644 and 1649, from 1651 to 1654, and from 1655 to 1665. He was bold and energetic, a sincere and zealous Puritan, rigid in his principles, and severe in the execution of the laws against those who differed from the religion of the colony. So averse was he to everything savoring of popery, that he cut out the cross from the military standard. He was opposed to long hair, insisted that the women should wear veils in public assemblies, and did all in his power to establish what he deemed a pure church. During his administration four Quakers were put to death in Boston.

ENDLICHER, Stephan Ladislaus, a Hungarian botanist and linguist, born in Presburg, June 24, 1804, died in Vienna, March 28, 1849. He studied at the universities of Pesth and Vienna, and intending to become a clergyman, he en-

tered subsequently the archiepiscopal seminary in the latter city. After having received the minor clerical orders, he abandoned theology and devoted himself to the study of the natural sciences, especially botany. He continued at the same time his studies of the oriental languages, and obtained in 1828 a position in the court library of Vienna, where he was intrusted with the compilation of a new catalogue of the manuscripts. In 1836 he was appointed keeper of the court cabinet of natural history, and in 1840 professor of botany and director of the botanical garden of the university. During this period he exhausted his personal resources in supplying the institution with costly materials for the study of botany which the government failed to procure, and in publishing or aiding others in publishing valuable works. He corresponded with scientific men and institutions in every part of the world, and was one of the chief founders of the Vienna academy and of the *Annalen des Wiener Museums*. He presented his own choice library and rich herbaria to the state, and passed several hours every week for ten years in the society of the emperor Ferdinand; but he received no other reward than the title of *Regierungsrath*. The political turmoil of 1848 found him in pecuniary embarrassment, and becoming known as a sympathizer of the popular party, he was made the butt of the intrigues of his enemies, which hastened his death. Some believe that he died by his own hand. He made valuable contributions to the science of old German and classic literature, and pointed out new sources of Hungarian history, publishing *Fragmenta Theotisca Versionis antiquissimæ Evangelii Matthæi* (edited with Hoffmann von Fallersleben, 1834); an edition of two poems of Priscian (1828); and *Anonymi Belæ Regis Notarii de Gestis Hungarorum Liber* (1827). His linguistic publications comprise *Analecta Grammatica* (with Eichenfeld, 1836), and *Anfangsgründe der chinesischen Grammatik* (1845). His *Verzeichniss der japanesischen und chinesischen Münzen des kaiserlichen Münz- und Antikencabinetts* (1837) and *Atlas von China nach der Aufnahme der Jesuitenmissionäre* (1843) are finely executed, and deserve mention as specimens of his great liberality. The majority and the most valuable of his works treat on botany. Foremost among them are his *Genera Plantarum* (1831-'41), in which he lays down a new system of classification; *Grundzüge einer neuen Theorie der Pflanzen-erzeugung* (1838); and *Die Medicinalpflanzen der österreichischen Pharmakopöe* (1842). The principal of his other botanical works are: *Ceratotheca* (1822); *Flora Posoniensis* (1830); *Diesingia* (1832); *Atacta Botanica* (1833); *Iconographia Generum Plantarum* (1838); *Enchiridium Botanicum* (1841); and *Synopsis Coniferarum Sancti Galli* (1847.) Besides these he wrote several works in conjunction with other scholars, and many of his minor writings are scattered among the periodicals of his time,

especially in the *Annalen des Wiener Museums*. (See BOTANY.)

ENDOGENS (Gr. ἐνδον, within, and γένειν, to produce), a class of plants so called because their stems increase in diameter by the deposition of new woody matter in the centre, in contradistinction to exogens, whose stems increase by the formation of a new layer of wood outside of that previously formed, and immediately beneath the bark. In endogens the stem has no medullary rays, concentric rings, or apparent distinction of pith, wood, and bark, but consists of fibres of woody or vascular tissue, distributed with little apparent regularity through the cellular system of the stem. They may be traced from the base of the leaves downward, some passing into the roots, and others curving outward until they lose themselves in the rind or cortical integument, which differs from the bark of exogens in that it does not increase by layers, and cannot be separated from the wood. As the plant grows, new threads or fibres spring from the freshly formed leaves, and passing first down the centre of the stem crowd the old ones out, and are finally directed toward the rind. In some plants the rind, being soft, is capable of unlimited distention; in others it soon indurates, and the stem consequently ceases to grow in diameter. The best example of this class of plants is the palm, whose branchless trunk, rising from 30 to 150 feet from the ground, and terminated by a simple cluster of foliage, has a striking and majestic appearance. The growth of this tree is from the terminal bud, and if the bud is destroyed the tree perishes. In some instances, as in the doum palm of Upper Egypt, and the pandanus or screw pine, two terminal buds appear and branches then shoot forth. The asparagus is an example of endogenous growth. Endogens are monocotyledonous; the veins of their leaves are almost uniformly in parallel lines connected by simple transverse bars; their flowers are trimerous, or have their sepals, petals, stamens, and styles in threes. They luxuriate in hot and humid climates, and comprise the greater number of plants contributing to the food of man, and but a small proportion of poisonous plants. They are generally shorter lived than exogens, though the dragon tree and others, whose growth is not limited by the hardening of the cortical integument of the stem, may attain a great age. The average age of the palms is perhaps 200 or 300 years.

ENDOR, a town of Palestine, W. of the Jordan, assigned to the tribe of Manasseh, although situated within the territory of Issachar. It was in a solitary valley, not far from this town, that the sorceress resided whom Saul went to consult on the evening before the fatal battle of Gilboa.

ENDOSMOSE (Gr. ἐνδον, within, and ὥσμις, impulsion), the action exhibited by one of two fluids of different densities and composition in passing through an organic membrane which separates them, till they become both of the

same density. Let a solution of sugar in a tube closed below with a slip of bladder tied across the end, and open above, be suspended in a vessel of water. The quantity of liquid in the tube is soon seen to increase by the passing through of the thinner fluid. It may even flow over and run down into the outer vessel, and so the action will go on until the membrane becomes partially decomposed, or until the two mixtures become uniform. Dutochet, who first observed this phenomenon, found that the height to which the fluid would rise increased with the density of the thicker fluid. With a membrane $1\frac{1}{2}$ in. in diameter and sirup of the density 1.083, the liquid rose, in a tube $\frac{1}{2}$ of an inch in diameter, more than $1\frac{1}{2}$ in. in $1\frac{1}{2}$ hours; with sirup of a density of 1.45 the fluid rose nearly 3 in.; and when the density was 1.228 the rise was 4 in. A considerable force is exerted in this movement; in sirup of density 1.3 Dutochet estimated it to be equal to the pressure of $4\frac{1}{2}$ atmospheres. If the flow is drawn inward, the action is called endosmose; if outward, exosmose. It is supposed to be on this principle that the sap ascends in trees and fluids are diffused through animal bodies. Liebig, after describing some experiments, in which fluids were made to pass through nine membranes, to fill the vacant space left by evaporation of another fluid in a glass tube, remarks with reference to the application of the results to the processes taking place in the animal body as follows: "The surface of the body is the membrane from which evaporation goes constantly forward. In consequence of this evaporation, all the fluids of the body, in obedience to atmospheric pressure, experience motion in the direction toward the evaporating surface. This is obviously the chief cause of the passage of the nutritious fluids through the walls of the blood vessels, and the cause of their distribution through the body. We know now what important functions the skin (and lungs) fulfil through evaporation. It is a condition of nutrition, and the influence of a moist or dry air upon the health of the body, or of mechanical agitation by walking or running, which increases the perspiration, suggests itself." Interesting examples of this phenomenon are seen in the passage of the gases through membranes. If a tumbler, filled with air and covered at top with a thin sheet of India rubber, be placed under a bell glass filled with hydrogen, the gas will soon penetrate the cover and mix with the air; and this action will go on till the India rubber bursts open from the increased bulk of the contents of the tumbler. If the tumbler contained hydrogen and the bell glass air, the India rubber would be pressed in by the escape of the gas, leaving the portion remaining of greatly reduced density.

ENDYMION, in Greek legend, a shepherd of remarkable beauty, who retired every night to a grotto of Mount Latmus in Caria. As he slept the goddess Selene (the moon) became enamored of him, and leaving her chariot came

down to him. The eclipses of the moon were attributed to these visits. By Selene he had 50 daughters. Jupiter condemned him to perpetual sleep, or, according to other accounts, to 50 years of sleep.

ENFANTIN, Barthélemy Prosper, generally known under the name of Père Enfantin, one of the founders of St. Simonism, born in Paris, Feb. 8, 1796, died there, Sept. 1, 1864. He was the son of a banker, and with his fellow pupils was dismissed from the polytechnic school after March 30, 1814, for having on that day fired on the allied troops. He then became a commercial traveller, and in 1821 entered a banking house in St. Petersburg. He returned to France in 1823, and became cashier of a mercantile firm, at the same time joining the carbonari. In 1825 he made the acquaintance of Olinde Rodrigues, a follower of Saint-Simon, who introduced Enfantin to his teacher. After the death of Saint-Simon, May 19, 1825, Enfantin and Rodrigues began the publication of a journal, *Le producteur*, in which Enfantin broached new social and religious doctrines, which displeased many who at first supported it, and it was discontinued toward the end of 1826. Enfantin, however, continued to advocate his views by lectures and public meetings. The revolution of 1830 favored the movement, which was soon formally organized with Enfantin and Bazard as the chief leaders (*pères suprêmes*), and with the *Globe* newspaper, of which Michel Chevalier was editor, as its organ. A schism soon broke out between the leaders. Enfantin proposed the overthrow of all legislative and social restraint in the sphere of love and affection, except that of the "priest" or "confessor," who should have full command over the body and soul of his disciples for the control of their passions. Bazard declared this an attempt to convert Saint-Simon's economical doctrines into a religious creed, and a social order founded upon licentiousness, and withdrew in 1831. His secession was followed by that of the economical and political section of the school. But Enfantin persisted in his endeavors to establish a new religion. He addressed his followers (whom he estimated at 40,000 in France alone) with the authority of a superior being set apart by Providence for the purpose of inaugurating a new era for humanity through the emancipation and the agency of woman. He endeavored to find the female Messiah (*femme Messie*) who in his opinion was predestined to bear to him a new saviour of mankind, and in this search is said to have spent more than 250,000 francs in splendid entertainments. He still gained adherents and procured a loan of 80,000 francs for the establishment of industrial workshops. His meetings were closed by the authorities in May, 1832; but he now withdrew with 40 of his followers, among whom were Michel Chevalier and other eminent men, to some land which belonged to him in the vicinity of Paris, near Ménilmontant,

where they established a community and spent their time in manual labor and St. Simonian religious ministrations, over which Enfantin presided. Again arraigned by the government, Enfantin appeared in the court with two ladies as his counsel; but they were not permitted to plead his cause. After two days he was found guilty, and sentenced to a year's imprisonment, but was pardoned after a few months' detention. He spent two years in Egypt, then returned to France, devoted himself to agricultural pursuits, and was postmaster near Lyons. By the influence of his former disciples and associates he became in 1841 a member of the scientific board for Algeria. From 1845 to 1848 he was director of the Lyons railway. In November, 1848, he established, in concert with M. Duveyrier, a daily journal, *Le Crédit*, with a view of reconciling political reforms with his Utopian views of social relations; but the journal was discontinued in 1850. He again received an appointment in connection with the administration of railways, which he held until his death. His writings are not numerous. Among the principal are: *Traité d'économie politique* (1830); *La religion saint-simonienne* (1831); *Correspondance philosophique et religieuse* (1847); *Correspondance politique* (1849); and *Réponse au P. Félix* (1858). A few months before his death he published *La vie éternelle*, a kind of religious and political testament (Paris, 1863).

ENFIELD, a town of Hartford co., Connecticut, bordering on Massachusetts, situated on the E. bank of the Connecticut river, and on the New Haven, Hartford, and Springfield railroad, 14 m. N. of Hartford; pop. in 1870, 6,322. It was settled in 1681, and formed part of Springfield, Mass., till 1752, when it was annexed to Connecticut. It is connected with Suffield on the opposite bank of the river by a bridge constructed in 1808, the first one built across the stream in this state. A mile or two below is an iron truss bridge, 1,525 ft. long, erected in 1866 at a cost of \$265,000, over which the railroad crosses to Windsor Locks. A canal $5\frac{1}{2}$ m. long has been constructed around the falls of the Connecticut in this town, which is intersected by the Scantic and Freshwater rivers, branches of that stream. Enfield contains the villages of Thompsonville and Hazardville, the former being noted for its carpet factory, which contains 297 looms, and manufactures 2,600,000 yards annually, and the latter as the seat of one of the most extensive powder mills in the world. There are also manufactories of sewing machines, ploughs, carriages, sashes and blinds, harness, hats, bricks, distilled spirits, ale, and porter; a savings bank, a trust company, and several schools and churches. The town contains a community of Shakers, who are especially noted for their culture of garden seeds.

ENFIELD, a market town and parish of Middlesex, England, 9 m. N. by E. of London; pop. of the parish about 13,000. It is noted as the

seat of an ancient palace, now half ruined, built in the time of Henry VII., and of the government manufactory of the rifles which take their name from this place. The term "Enfield rifle" does not denote any particular improvement, but the result of a series of improvements on the old musket. (See *RIFLE*.)

ENFIELD, William, an English theologian, born in Sudbury, March 29, 1741, died in Norwich, Nov. 3, 1797. He was a dissenter, and in 1763 was chosen pastor of a congregation in Liverpool, where he remained seven years, and published some devotional works and two volumes of sermons. He was professor of belles-lettres in the academy at Warrington from 1770 to 1783, and was subsequently pastor in Norwich. His "Biographical Sermons on the Principal Characters of the Old and New Testament" are not only valuable as aids to interpretation, but exhibit considerable force of thought and elegance of expression. He published an abridgment of Brucker's "History of Philosophy," and a work entitled "Institutes of Natural Philosophy," and wrote many articles in Aikin's "Biographical Dictionary." He was also the compiler of "The Speaker," a very popular collection of pieces for reading and reciting in schools.

ENGADINE, or *Engadin*, or *Valley of the Inn*, a beautiful valley of S. E. Switzerland, near the sources of the Inn, at an altitude varying from 3,500 to 6,100 ft. above the sea, and extending along the banks of the Inn, through the canton of the Grisons, between two principal chains of the Rhaetian Alps, from the Maloja, which separates it from the picturesque valley of Brigell, to the gorge of Finstermünz, on the confines of the Tyrol; length, nearly 60 m.; average breadth between 1 and 2 m.; pop. about 12,000, all Protestants, with the exception of the valley of the Tarasp, which is Catholic. The valley is divided into Upper Engadine, with the watering place of St. Moritz, and the villages of Silva Plana, Samaden, Bevers, &c., and Lower Engadine, with Zernetz, Tarasp, the mineral springs of Scuols, &c. It has more populous villages than any other Alpine valley at so great an elevation, and it has at least 20 important tributary valleys. The tops of the surrounding mountains are inaccessible rocks, and the sides are sometimes covered with glaciers. The valley and the lower part of the mountains are susceptible of cultivation, but are for the most part occupied by forests or used for pasture lands. The climate is so cold and severe that cattle have to be kept indoors during seven or eight months of the year, but during the short summer the valley is visited by large numbers of tourists. The only grain raised is rye, and barley and potatoes seldom mature. The valley was for some time subject to Austria, which lost it in 1623. Most of the male population emigrate at an early age, in order to become rich, and then return to their native valley. Some of the higher Alpine pastures are let

ENGLAND AND WALES

every summer to Italian shepherds. The natives speak the dialect called Romansh.

ENGELMANN, George. See p. 824.

ENGHIEN, Louis Antoine Henri de Bourbon, duke d', a French prince, of the Condé family, born in Chantilly, Aug. 2, 1772, executed at Vincennes, March 21, 1804. He served under his grandfather, Prince Louis Joseph, at the outbreak of the revolution in 1789, and accompanied him and his father into exile. He bore arms against revolutionary France in the famous corps of royalist emigrants commanded by his grandfather, and distinguished himself by bravery and humanity to his prisoners. On the disbanding of the corps in 1801 he fixed his residence at a château near Ettenheim, Baden, being impelled to that choice, it is said, by his affection for the princess Charlotte de Rohan, who lived in Ettenheim, and to whom he was perhaps secretly married. Though it does not appear that he took part in any subsequent plots against the first consul, he was generally looked upon as a leader of the *émigrés*, and was suspected of complicity in the attempt of Cadoudal to take Bonaparte's life. The reports of spies gave some color to these surmises, for it appeared that he was frequently absent for 10 or 12 days together, at which times it was supposed that he secretly visited Paris. It was thought that an unknown person who had been seen to visit Cadoudal at Paris, but who afterward proved to be Pichegru, could be none other than the young duke. Anxious to terrify the royalists, and to put a stop to their attempts upon his life, Bonaparte resolved to seize and execute the duke, and

sent Gen. Ordener with 300 gendarmes to make the capture. The soldiers surrounded the château on the night of March 15, 1804, arrested the duke in his bed, and conducted him immediately to Strasburg, whence he was removed on the 18th to the fortress of Vincennes. He had received warning from Talleyrand and from the king of Sweden, through his minister at Carlsruhe, but his escape had been prevented by the delay of the Austrian authorities in forwarding a passport. The prisoner reached Vincennes on the evening of the 20th, and a few hours afterward a court martial, presided over by Gen. Hullin, assembled in the fortress. A mock trial was gone through, and, without the examination of witnesses or written testimony, the duke was found guilty on various charges of treason, and at once led out to execution. His requests to see the first consul and to be allowed a confessor were denied. He was shot by torchlight between 4 and 5 o'clock A. M., in the ditch outside the walls, and his body was thrown, dressed as it was, into a grave which had been dug the day before. Bonaparte and his chief instruments took every pains to justify their conduct, and it has never been known who of them was most guilty.

ENGLAND (Lat. *Anglia*; Fr. *Angleterre*), a country of Europe, forming with Wales the southern, larger, and more important division of the island of Great Britain, and the principal member of the United Kingdom of Great Britain and Ireland. This division is bounded N. by Scotland, E. by the North sea, S. by the English channel, separating it from France by distances increasing westward from 21 m. at

Great Seal of England.

the strait of Dover to 100 m., S. W. by the Atlantic, and W. by St. George's channel and the Irish sea, dividing it from Ireland, and having an average width of about 90 m. It lies between lat. 49° 57' and 55° 46' N., and lon. 1° 46' E. and 5° 45' W.; its greatest length N. and S. is 365 m., and its greatest breadth 280

m. Its shape bears some resemblance to a triangle, the apex being at Berwick-on-Tweed, the northernmost point in England, and the extremities of the base at the South Foreland, near Dover, and the Land's End, at the S. W. point of Cornwall. The distance in a direct line from Berwick to the South Foreland is

345 m.; from the South Foreland to the Land's End, 317 m.; and from the Land's End to Berwick, 425 m.; making a total perimeter of 1,087 m., but following the sinuosities of the coast the perimeter is about 2,000 m. The area of England is 50,922 sq. m.; that of Wales 7,398 sq. m. The divisions of England are very ancient, the counties being substantially the same now as they were ten centuries ago, though a few have been made in later times. Each county is subdivided into hundreds, and the hundreds into parishes. London is the metropolis of the United Kingdom, and among the other principal places are Liverpool, Manchester, Birmingham, Leeds, Sheffield, Bristol, Bradford, Stoke-upon-Trent, Newcastle, Hull, Portsmouth, Brighton, Southampton, and York. The following table shows the population of the counties in 1861 and 1871, and the county towns:

COUNTIES.	POPULATION.		COUNTY TOWNS.
	1861.	1871.	
Bedford.....	135,265	146,256	Bedford.
Berks.....	176,103	196,445	Reading.
Buckingham.....	166,597	175,570	Aylesbury.
Cambridge.....	173,950	186,363	Cambridge.
Cheshire.....	505,153	561,131	Chester.
Cornwall.....	369,323	362,098	Bodmin.
Cumberland.....	205,293	220,245	Carlisle.
Derby.....	329,377	350,598	Derby.
Devon.....	584,531	600,814	Exeter.
Dorset.....	158,651	195,544	Dorchester.
Durham.....	509,018	685,045	Durham.

Wales, which was incorporated with the English monarchy in the time of Edward I., is divided into 13 counties, with an aggregate population in 1861 of 1,111,795, and in 1871 of 1,216,420. The aggregate population of England and Wales in 1871 was 22,704,108, of

whom 11,040,403 were males and 11,663,705 females. The number of marriages registered in 1871 was 190,015; births, 797,143; deaths, 515,096; the mortality being thus a little less than 22·7 per 1,000, and the natural increase 282,047, or 12·9 per 1,000 nearly. The increase of the population in England and Wales from 1861 to 1871 was 2,637,884, or 13·15 per cent., being an average annual increase of 1·24 per cent.—The most important rivers are the Medway, Thames, Stour, Orwell, Great Ouse, Nene, Welland, Witham, Humber (with its branches the Trent and Ouse), Tees, Wear, Tyne, and Tweed, flowing into the North sea; the Esk, Eden, Lune, Ribble, Mersey, Dee, Severn, Avon, Taw, and Torridge, which empty on the W. coast; and the Tamar, Exe, Frome, Avon (Hampshire), and Southampton water, which flow into the English channel. Many of these have broad estuaries and are navigable by large vessels. The English lakes, though few, are famed for their beauty. The picturesque districts of Westmoreland and Cumberland, in which are Ullswater (9 m. long, and from $\frac{1}{4}$ to 2 m. wide), Windermere, the largest lake in England (10 $\frac{1}{2}$ m. long, and from 1 to 2 m. wide), Bassenthwaite water, Derwentwater, Buttermere, Ennerdale water, &c., are favorite summer resorts. The seacoast is much broken, and abounds in fine harbors and roadsteads. On the east are the estuaries of the Medway, Thames, and Humber, and the Wash, into which empty the Great Ouse, Nene, Witham, &c.; on the west the broad Solway frith, between England and Scotland, Morecambe bay, the Bristol channel, and the estuaries of the Duddon, Ribble, Mersey, Dee, and Severn; and on the south Mount's bay, Falmouth harbor, Plymouth sound, Tor bay, the estuary of the Exe, Weymouth bay, Poole harbor, the Solent and Southampton water between Hampshire and the Isle of Wight, Portsmouth and Chichester harbors. Near the entrance of Dover strait into the North sea are the well known anchorage grounds called the Downs, opposite the towns of Deal and Sandwich. The E. coast presents an alternation of sandy beaches and chalk cliffs, hollowed out in many places into caves, and with several high promontories. The Atlantic tides form a strong current, sweeping S. along this coast, and continually wearing away the limestone cliffs and headlands; the encroachments of the sea have already buried large tracts of land. A submarine forest has been traced along a great part of the coast of Lincolnshire. On the sandy portions of the seaboard the opposite phenomenon is observed; portions of land have here been gained from the water, the town of Norwich, which is now near the centre of the E. division of Norfolk, having stood in the 13th and 14th centuries on an arm of the sea. The S. coast, from the South Foreland to beyond Folkestone, is characterized by lofty chalk cliffs, which are continually diminishing in height. It then gradually subsides into Rom-

ney marsh, W. of which the shore becomes alternately precipitous and flat. The W. is by far the most irregular of the English coasts. It is high and rocky as far as Minehead bay on the Bristol channel. North of Wales the shore consists of wasting cliffs of red clay and marl, of peninsulas which were probably once more elevated than now, of abrupt headlands, and toward Solway frith of sands and marshes. The most mountainous part of England lies N. of the rivers Humber and Mersey, and is traversed N. and S. by a range called the Pennine mountains or the northern range, connected with the Cheviot hills on the Scotch border, and terminating in Derbyshire. The highest summits rise to about 3,000 ft. West of this range are the Cumbrian mountains, occupying the central and southern portions of Cumberland, the larger part of Westmoreland, and the N. part of Lancashire. Their highest summits are Scalfell (3,229 ft.), Helvellyn (3,055), and Skiddaw (3,022). The Devonian range extends from Somersetshire to the Land's End, and its highest summit, Yestor Beacon, reaches a height of 2,077 ft. Three cross ridges occupy the S. E. part of the kingdom, extending from Salisbury plain, one S. E. to Beachy head, another E. to the E. shore of Kent, and the third N. E. into Norfolk. The famous South Downs, 50 m. long and 5 or 6 m. wide, are in the first, and the Surrey hills or downs in the second, both being celebrated for their sheep pastures. The Malvern hills extend over parts of the counties of Gloucester, Hereford, and Worcester. The Cotswold and Stroudwater hills are in Gloucester, and the Chiltern hills extend from Hertford, across Bucks, into Oxford. Between these ridges lie many beautiful vales; other parts of the country spread out in vast plains, such as the plain of York, which extends from the valley of the Tees to the confluence of the Ouse and Trent, 70 or 80 m., and others abound in rugged and picturesque scenery. Northumberland is largely occupied by moors, which also cover much of Lancashire, Yorkshire, Staffordshire, Cumberland, Westmoreland, and Durham. These are elevated tracts, in most places sterile, heath-grown, or gravelly. Those of the East Riding of Yorkshire alone cover an area of 400 or 500 sq. m. The wolds of Yorkshire, which closely resemble the chalk hills of many other counties, occupy about 500 sq. m.—The distribution of the geological formations through England is closely connected with that of its inhabitants, their industrial pursuits, and physical condition; all which indeed are in great measure controlled by the nature of the mineral productions and of the soil. Nearly all that portion of England lying E. of a line drawn from the mouth of the Tyne in Northumberland in a southerly direction through the towns of Nottingham and Leicester, thence S. W. nearly to Gloucester, and again S. to Bath and S. W. to Exmouth, consists of the upper secondary formations, including the oolite, lias, chalk, and

greensand; and on both sides of the Thames, widening as the formation extends N. along the coast of Suffolk, is the tertiary group of clays and sands, which constitutes the London basin, and rests in the depression of the chalk. Similar strata hide the secondary rocks over a small area about Southampton and the northern part of the Isle of Wight. In Lincolnshire a strip of alluvial skirts the coast, and stretches S., constituting the boggy district of Huntingdonshire and Cambridgeshire. Over this region of secondary rocks the prevailing dip is toward the S. E., so that the lower members of the series are in general met with in passing from the eastern coast westward. They constitute narrow belts, which are traced with great uniformity in their line of bearing, or N. E. and S. W. Thus from Weymouth to the Humber one may continue on that bed of the middle oolite called the Oxford clay, the average thickness of which does not exceed 500 ft. A little further west, from Bridport in Dorsetshire to Flamborough head on the coast of Yorkshire, the topography, rocks, and soil all designate the chalk formation of earlier date; but west of this, on the line from Lyme Regis to Whitby, the limestones of the lias appear in the general order of older rocks in a westerly direction. Over all this region no mines of coal or of metallic ores are found. The easily disintegrated strata present no bold hills, except in the cliffs of chalk abutting upon the coast, but are spread out in elevated plains, and gentle undulations and hills of smoothly rounded outlines. The calcareous nature of the strata secures fertility to the soil; and the region is distinguished for its agricultural character. West of this, occupying a belt not many miles wide, is the manufacturing district of England, made so by the mines of coal and iron ore along its range. They occur at intervals in isolated basins of moderate area, but remarkably productive in coal by the close grouping of the beds and the great depths to which they are carried by the steepness of the dip. These basins are often overlaid in part by the sandstones and marls of the new red sandstone formation, which rests upon the upturned edges of the strata of the coal formation. The marls afford rock salt and strong brine springs, which have long been advantageously worked in Cheshire, and near Droitwich in Worcestershire. Associated with the salt are valuable beds of gypsum. The coal fields are too numerous to be all particularly named. That of Newcastle extends from the N. E. extremity of England to the river Tees, along the coast of Northumberland and Durham; it is traced further S. to Leeds, but this portion has only the lowest beds, which are of little importance. The Yorkshire and Derbyshire extends S. from Leeds to near Derby, and covers in its northern portion a breadth of about 25 m. Some small but very productive coal basins lie S. W. of Derbyshire, of which that near Coventry is the most southern locality

of coal in the midland counties. On the N. W. is the Cumberland and Whitehaven coal field, extending along the coast to the north of Maryport; some of its mines have been worked beyond low-water mark, and the convenience of shipping gives a high importance to their products. The Lancashire coal field lies W. of a range of hills that extends along the borders of this county and Yorkshire, separating the two coal fields by the underlying shales and millstone grit of which they are composed. The strata of the coal formation on the W. side dip toward the west, and the margin of the field in this direction reaches to Prescot, near Liverpool, and extends N. E. toward Colne. A little beyond the southern extremity of the Lancashire coal field is that which supplies the potteries near Newcastle in Staffordshire, and which, with those referred to as lying S. W. of Derbyshire, makes up the central coal district as grouped by Conybeare and Phillips. These include the fields of Ashby de la Zouch and Warwickshire. In the South Stafford or Dudley coal field the coal has been worked in a single bed 30 ft. thick, and at one locality it has reached a thickness of more than 45 ft. The western coal district comprises the mines in North Wales, the island of Anglesea, and Flintshire. The middle western or Shropshire district comprises those of the Clec hills, Colebrook dale, Shrewsbury, &c.; the south-western district, those of the Forest of Dean, South Gloucester, and Somerset, on both sides of the river Avon, and the coal field of the S. coast of Wales, bordering the British channel for 100 m. E. and W., and stretching inland toward the north from 5 to 20 m. This field is in convenient proximity to the copper mines of Cornwall, the ores from which are transported to the great smelting establishments on tide water near the coal mines. Much of the coal of this region is semi-anthracite, like that of the Cumberland coal field of Maryland, and some is true anthracite. The latter was first successfully applied upon a large scale to the smelting of iron ores in this district at the Crane iron works. Iron ores abound in the coal measures of this field as well as in many of the others, especially that of Dudley and Wolverhampton, near Birmingham. The same measures also yield fire clay and limestone, and the millstone grit which underlies and holds as in a cup the coal measures furnishes a most durable building stone. Besides the coal measures scattered over the area in which coal and iron are found, and the newer formations which here and there overlie them, there are frequent patches, like islands, of rocks of older date, which have intruded through the carboniferous strata and the later formations above them. These are of granite, syenite, and metamorphic slates. Some are basaltic dikes, and one such of extraordinary extent appears from under the alluvium on the coast of the North sea, near Harwood dale, and is thence traced toward the N. W. across the Tees to the

western part of Durham. It traverses strata of the lias, oolite, the coal measures, and of the metalliferous or mountain limestone of the lower carboniferous group. Its length is from 50 to 60 m., and in some places it is seen only 25 to 30 ft. thick, dipping at a steep angle. The mountain limestone is productive in lead, copper, and zinc ores in three districts of England. Veins of galena near Alston moor in Cumberland traverse adjoining beds of limestone and sandstone, yielding well in the former and poorly in the latter. Others are found in the same county, as also in Durham and Yorkshire, in the upper portions of the valleys of the Tyne, the Wear, and the Tees. Pyritous copper is obtained S. W. of Alston moor, and near Ulverstone beds of red hematite alternate with those of the same limestone. A second district is in Derbyshire and the contiguous parts of the neighboring counties. Zinc blende is economically worked in this district, which also includes the copper mine of Ecton in Staffordshire. The third district is in the N. E. part of Wales, where mines of galena and calamine have long been profitably worked, lying partly in the mountain limestone and partly in older formations. Bordering the coal fields frequently are seen the strata of the old red sandstone and other rocks of the Devonian series; and from beneath these appear the older and lower fossiliferous strata of the Silurian and Cambrian formations; they produce little of economical importance. The metalliferous districts of Cornwall and Devonshire are noticed in the articles upon those counties. The granitic rocks and metamorphic slates, such as are seen in this portion of England, are repeated in North Wales, where the argillaceous slates are worked in the immense quarries near Bangor. The same rocks occur again in the N. W. part of Yorkshire and Lancashire, and are traced through Westmoreland and Cumberland into Scotland. The granite, often disintegrating rapidly, produces the white clay called kaolin, which is used in making fine porcelain; but it affords little good building stone, and there are no important quarries of this rock in England. Good building stone is not readily found in any of the formations; and the want of durable materials is the more sensibly felt because the humid atmosphere produces a rapid disintegration of stone exposed to it. England is deficient in fine marbles and in good iron ores. The best of the latter are the hematites; but those chiefly employed in the immense production of iron are the poor argillaceous ores of the coal formation. For making the excellent cast steel for which English manufacturers are celebrated, the better iron from the magnetic and specular ores of Norway and Sweden is largely imported. The annual produce of salt is over 1,000,000 tons, a large part of which is exported to America. —The climate is subject to considerable variations of heat and cold, and of dryness and moisture, but the winters are not severe for

the latitude, and the heat of summer is often relieved by periods of cool weather. The atmosphere is chilly and damp, and particularly moist in the western counties, but the E. coast is the colder. The mean annual temperature of the S. W. at sea level is about 52°; at Greenwich, 49°; at Penzance, 51·8°. There is thus an increase of mean temperature from N. to S. and from E. to W. July and August are the hottest months; December and January are the coldest, the thermometer in the latter two near London having a mean height of 39·7°. The W. and S. W. are the most prevalent and constant winds, but a blighting N. E. wind blows in April and May on the E. coast, doing great damage to the crops and live stock of Norfolk and Kent. The dry parching character of the latter renders it deleterious to health, but the S. W. winds, which come from the Atlantic, are moist and genial, and it is on their greater frequency that the general salubrity of the climate depends. Notwithstanding the humidity of the climate, the average fall of rain is less than in the northern United States. For the British islands it is given as 32 in., while at Cambridge, Mass., it is stated by Prof. Guyot to be 38 in., and at the Western Reserve college, Ohio, it was found by Prof. Loomis to be 36 in.—The general character of the soil is that of great fertility, and seven ninths of the land is available for cultivation. The principal cultivated crops are wheat, oats, beans, barley, rye, turnips, potatoes, clover, hops, and flax. Few of the forests are extensive, but the country is well wooded, most of the timber being found in small plantations belonging to private individuals. There are some very large forest lands, however, such as the New forest in Hampshire, Dean forest in Gloucestershire, and Sherwood in Nottinghamshire, which are the property of the crown. The principal trees are the oak, ash, mountain ash, fir, beech, sycamore, maple, poplar, elm, larch, pine, chestnut, horse chestnut, and willow. There are not many indigenous fruits; the pear, crab, medlar, wild cherry, bullace, raspberry, blackberry, gooseberry, currant, strawberry, and cranberry are the most important species. Foreign fruits, however, except such as require a powerful sun to bring them to maturity, are found to thrive. Of the small herbaceous plants, besides the common grasses covering the country with verdure which the winter seldom destroys, may be mentioned the daisy, primrose, cowslip, violet, hyacinth, harebell, tamarisk, musk, gentian, foxglove, henbane, hemlock, and nightshade.—Many of the wild animals which formerly inhabited the forests, such as the bear, wolf, wild boar, and wild cat, have disappeared; and the stag, fallow deer, and roe have been preserved only by strict game laws. The other indigenous wild quadrupeds are the fox, badger, polecat, beech and pine martens, otter, weasel, stoat, hedgehog, mole, squirrel, hare, rabbit, dormouse, lemming, shrew, and several varieties of the rat and mouse. More than 270

species of land and water birds have been noticed, of which 20 are birds of prey and 80 are gallinaceous. The bustard seems to be the only bird which has become extinct. Of about 170 species of fish which frequent the coasts, rivers, and lakes, the chief are the herring, pilchard, mackerel, sprat, cod, and salmon. The sea fisheries are chiefly of cod, mackerel, oysters, and lobsters.—The various improvements which modern science has introduced in agriculture are generally adopted in England, and under careful management the land, which once with difficulty supported a population of 10,000,000, now easily maintains more than double that number. The best systems of drainage are employed, not as formerly in marshy grounds alone, but on nearly all farms. Artificial manuring receives due attention, and steeps which a few generations ago would have been thought waste land are now under profitable culture. English husbandry, however, has risen to its present high state very slowly. The farms are small, averaging in England and Wales about 111 acres each, but there are comparatively few land owners, most of the farms being held by tenants at will or by lease. The best tilled counties are those of the E. coast. The capital used in agriculture is about £186,000,000; rent of farms, £60,000,000. Cattle raising is a most important branch of husbandry, and the country has been famous for live stock since the days of Cæsar. Somewhat more than half the arable land is used for grazing, the best pastures being found in Buckinghamshire, Kent, Middlesex, and several of the western and mid-land counties. In the last are bred good dray horses. Yorkshire is noted for carriage horses, and an excellent breed for farm labor is raised in Suffolk. The English race horse is renowned for speed and beauty. Lancashire is noted for its long-horned cattle; Northumberland, Durham, Devonshire, Herefordshire, and Sussex, for their short-horned breeds; and Suffolk for its duns. Essex, Cambridgeshire, and Dorsetshire are celebrated for good butter; Cheshire, Gloucestershire, Wiltshire, other western counties, and Leicestershire, for cheese. The well known Stilton cheese is made in Leicestershire. The sheep are highly prized for the quality both of their flesh and of their wool. In 1872 there were in Great Britain 9,573,551 acres in grain crops, 3,616,383 in green and other crops, 4,513,451 in clover and grasses under rotation, and 12,575,606 in permanent pasture. There were 2,115,068 horses, 5,624,994 cattle, 27,921,507 sheep, and 2,771,749 swine.—The manufactures of England are commensurate with her greatness in other respects. The most important is that of cotton, which employs more hands than any other in the kingdom, and furnishes about two fifths of the exports. The principal seats of this manufacture are Lancashire, Cheshire, Derbyshire, and Yorkshire. The census of 1871 gives the statistics of the leading textile manufactures of England and Wales as follows:

MATERIALS.	No. of factories.	Spindles.	Power looms.	Operatives.
Cotton.....	2,371	32,613,631	411,386	414,970
Wool.....	1,550	2,193,342	37,356	100,640
Shoddy.....	120	133,793	2,690	8,816
Worsted.....	539	2,068,576	63,445	166,514
Flax.....	155	402,288	3,043	19,816
Silk.....	692	1,117,798	12,185	47,311

The imports of cotton for 1871 were 1,778,139,776 lbs.; exports, 368,234,160 lbs.; retained for home consumption, 1,409,905,616 lbs. The imports of wool for 1871 were 323,036,299 lbs.; exports, 135,089,794 lbs.; retained for home consumption, 187,946,505 lbs. The chief woollen and worsted manufactories are in Yorkshire, Lancashire, and Gloucestershire. The raw material is mostly domestic, though for some years past large quantities have been imported. The great centres of the hardware manufactures are Birmingham and Sheffield, the former having workshops of iron, steel, copper, and brass, and the latter being famous chiefly for cutlery, agricultural implements, grates, fire irons, &c. Linen is manufactured to some extent in Leeds and the counties of Lancaster, Dorset, Durham, and Salop. The silk manufacture made great progress under the tariff of 1826, before which date it was unable to compete with France and Italy. The glove trade of the midland and western counties is important, the principal establishments being at Woodstock, Worcester, Ludlow, Hereford, and Yeovil. The vast number of establishments engaged in the book and newspaper publishing business gives a strong impetus to the production of paper. Distilling is carried on to much smaller extent than in Scotland and Ireland, but the breweries are very numerous, and many of them on the largest scale. The quantity of malt charged with duty in 1872 was 57,308,082 bushels; free of duty, 6,082,284; home consumption, 61,608,569. Among other important manufactures are hats, glass, pottery, soap, lace, &c. Ship building is also a prominent branch of industry. —The commerce of England, until the rise of the trading and maritime power of the United States, had long been without a parallel. Her situation is in the highest degree favorable; the hardihood, industry, and enterprise of her people have turned her natural advantages to account, and there is no accessible part of the world with which she has not established commercial relations. With Ireland she has a trade in grain and provisions in exchange for manufactured goods; from N. Europe she receives timber, iron, flax, hemp, pitch, tallow, potash, and wheat; from central Europe, agricultural produce, silk, linen, lace, gloves, timber, flax, wine, and gin; from S. Europe, wine, brandy, fruit, drugs, silk, &c.; from the United States, cotton, tobacco, rice, grain, flour, and petroleum, the imports thence being considerably inferior in value to the exports; from South America, hides, skins, indigo, cochineal, and bullion; from Asia, tea, coffee, sugar, indigo,

drugs, cotton, piece goods, and ivory; from Africa, drugs, ivory, teak wood, and hides. Manufactured goods are the staples furnished by England in exchange for all these commodities. The following table shows the value of the commerce of the United Kingdom for four years ending with 1872:

YEARS.	Imports.	EXPORTS.		
		Produce and manufactures of the United Kingdom.	Foreign and colonial merchandise.	Total exports.
1869...	£295,460,214	£189,953,957	£47,061,095	£237,014,052
1870...	308,257,493	199,586,822	44,493,755	244,080,577
1871...	331,015,450	223,066,162	60,508,583	283,574,700
1872...	354,698,624	256,257,347	58,331,487	314,588,834

The following table shows the value of the imports of the United Kingdom from and exports to the chief British colonies and the principal foreign countries in 1872:

COUNTRIES.	Imports.	Exports.
BRITISH POSSESSIONS.		
India.....	£33,652,156	£18,471,394
Australasia.....	15,625,866	14,141,673
Canada and North America.....	9,130,919	10,193,277
West Indies.....	5,082,297	2,438,570
Ceylon.....	8,163,153
Cape and Natal.....	3,717,465	3,705,554
Straits Settlements.....	3,505,114	2,420,072
Gulana.....	1,862,977
Hong Kong.....	2,572,673
Gibraltar.....	1,139,023
All other possessions.....	4,102,906	5,123,461
Total British possessions.....	£79,372,853	£60,555,997
FOREIGN COUNTRIES.		
United States.....	£55,663,948	£40,736,597
France.....	41,893,444	17,268,589
Russia.....	24,320,333	6,600,224

Colombia.....	3,150,337
Japan.....	1,961,827
Mexico.....	843,186
All other countries.....	7,513,739	7,566,307
Total foreign countries.....	£275,320,771	£195,701,350
Total imports and exports.....	£354,698,624	£256,257,347

The six principal articles of import into the United Kingdom, with their value in 1870-'72, were:

ARTICLES.	1870.	1871.	1872.
Cotton, raw.....	£53,469,753	£55,907,070	£53,380,670
Corn and flour.....	34,169,644	42,502,252	51,228,516
Sugar, raw and refin'd	17,184,868	18,188,417	21,187,601
Wool, sheep and othr	15,812,598	17,940,639	18,523,350
Silk manufactures...	15,171,291	8,397,324	9,141,573
Tea.....	10,097,619	11,635,644	12,933,143

The six principal articles of export are :

ARTICLES.	1870.	1871.	1872.
Cotton manufactures	£71,410,131	£72,821,411	£80,164,155
Woolen and worsted manufactures.....	26,821,217	33,283,112	38,493,411
Iron and steel.....	24,083,090	26,124,134	35,996,167
Linen manufactures.....	9,435,835	9,741,664	10,956,761
Coals, cinders, and culm.....	5,506,890	6,267,047	10,442,321
Machinery.....	5,256,508	5,966,941	8,201,112

The total number and tonnage of sailing and steam vessels that entered and cleared at the ports of the United Kingdom in 1872 are exhibited in the following statement :

COUNTRIES.	ENTERED FROM.		CLEARED FOR.	
	No. Vessels.	Tons.	No. Vessels.	Tons.
BRITISH POSSESS'NS.				
Channel islands....	1,623	248,650	1,609	226,160
East Indies.....	965	877,944	1,126	1,075,031
Australia.....	242	235,716	411	390,955
North America.....	1,540	1,302,972	1,509	1,073,544
West Indies.....	689	211,973	504	174,529
British Guiana.....	107	47,090	206	76,502

Total foreign and colonial.....	64,728	21,015,415	64,883	21,485,610
Coasting trade.....	136,394	18,099,150	136,130	17,922,897
Aggregate.....	201,122	39,114,565	201,013	39,408,507

Of the total number of vessels that entered, 36,822 of 14,173,289 tons were British, and

27,906 of 6,842,126 tons were foreign; and of those that cleared, 37,149 of 14,545,801 tons were British, and 27,734 of 6,939,809 tons were foreign. The above statistics are for the United Kingdom. For England, the entrances were 49,150 vessels of 15,331,948 tons in the foreign, 4,821 of 2,582,485 tons in the colonial, and 91,831 of 11,105,245 tons in the coasting trade; clearances, 49,340 vessels of 15,662,006 tons in the foreign, 5,743 of 3,134,855 tons in the colonial, and 100,613 of 11,789,499 tons in the coasting trade. In addition to the above, 1,501 vessels of 107,556 tons in the colonial and foreign trade, and 1,344 of 114,354 tons in the coasting trade, entered the Channel islands and isle of Man, and 1,510 of 86,235 tons in the foreign and colonial, and 707 of 77,211 tons in the coasting trade cleared. The total number of vessels registered for England under merchant shipping acts in 1872 was 20,097, with a tonnage of 4,510,556, including 17,290 sailing vessels of 3,290,025 tons, and 2,807 steam vessels of 1,220,531 tons. The total number of vessels built at ports of England, exclusive of vessels built for foreigners, was 687 of 236,871 tons, of which 345 of 34,159 tons were sailing, and 342 of 202,712 tons steam vessels. The ocean steam navigation of England is incomparable, and her lines of steam packets may be said to perform the mail service of the world. Steam vessels of iron are now extensively built.—The means of internal communication are superior to those of any other country. It is about a century since the English began to make good roads, though turnpikes were set up 100 years earlier. The total length of all roads in England and Wales, exclusive of paved streets and roads in towns, is about 100,000 m.; of the latter, 30,000. The canals of England are next in importance to those of Holland, and were commenced in the last century. The first railway was begun in 1825 and opened in 1830, and 6,621 m. of lines had been constructed in the United Kingdom in 1850, being at the rate of 265 m. per annum. At the end of 1860, 10,433 m. were open; at the end of 1872, 15,814. These lines had a total capital paid up at the end of 1872 of £569,047,346, had conveyed 422,874,822 passengers, besides season-ticket holders, and had received during the year £51,304,114. Of these lines there were in England and Wales 11,136 m., in Scotland 2,587 m., and in Ireland 2,091 m. The number of post offices in the United Kingdom at the beginning of 1873 was 12,200. The gross revenue of the post office department in 1872 was £5,208,922; cost of management, £2,754,764. The postal savings banks received £7,567,034, and paid out £5,402,644. The post office department was authorized by act of parliament, July 31, 1868, to buy up all the telegraph lines, and to charge the public a uniform rate irrespective of distance. A supplementary act was passed in 1869 making the telegraph a government monopoly like the post office. The purchases

were made late in 1869, and possession obtained in February, 1870, when there were 2,933 telegraph offices. At the beginning of 1873 there were 5,400 offices, of which 3,593 were postal offices, and 1,807 railway telegraph offices. The latter slightly decreased in 1870-'71, while the postal offices were greatly multiplied. Up to June, 1871, about £930,000 had been expended, besides the purchase money; 5,000 persons were employed, and the net receipts for about 14 months had been £798,580, at a current expense of £470,000. The investment of the government was thought to amount to a capital of £7,500,000, upon which it is believed that a reasonable interest is returned.—The public institutions of charity, of learning, of the arts, of education, and of religion are in great number and of high repute. Every considerable town has its hospitals, many of which are liberally endowed, its free schools, mechanics' institutes, &c. The principal cities possess galleries of arts, and several have valuable libraries. Compulsory provision for the poor has long been established in England. The whole country is divided into poor-law unions, over which are guardians elected by the rate payers. On Jan. 1, 1873, there were 736,201 outdoor paupers in receipt of relief; indoor paupers, 154,171. The total amount expended by the poor-law boards in England and Wales during the year ending Jan. 1, 1873, was £8,007,403; a decrease from the preceding year in actual amount, and a decrease in rate upon the average of several years. The number of charitable institutions other than schools in London alone in 1874 was about 600.—England has done much for the cause of education, but not so much as should have been done by so old, wealthy, and humane a nation. Among the higher institutions of learning are the universities of Oxford, Cambridge, and Durham; University college and King's college, London (the last two founded for the purpose of cheapening and popularizing academical instruction); college of preceptors, London; Owen's college, Manchester; Manchester New college; Queen's colleges, Birmingham and Liverpool; St. David's college, Lampeter; royal agricultural college, Cirencester; besides good foundation schools at Winchester, Eton, Manchester, Great Berkhamstead, Warrington, Shrewsbury, Birmingham, Tunbridge, Westminster, Highgate, Bedford, Ipswich, Repton, Rugby, Harrow, and London. The great public schools of Eton, Westminster, Harrow, Winchester, St. Paul's, the Charterhouse, and merchant tailors' school, are of the highest reputation, and have educated many of the distinguished men of England. Public education has made much progress within the last quarter of a century, though a great difference exists in the prevalence of elementary knowledge in different parts of the country. The uneducated are found in greater numbers among the mining and manufacturing populations than in the agricultural portions of the kingdom. The latest returns show that

one fifth of the adults in England are unable to write their names. By the school law of 1870 parliament ordered that sufficient accommodation in public elementary schools should be provided for all resident children, and that all children whose parents are unable to pay for their education shall be educated at the public expense, while the school boards shall have power to compel parents to give their children between the ages of 5 and 13 the advantages of education. The condition of the elementary schools in England and Wales subject to government inspection is shown in the following statement:

	Year ending Aug. 31,	
	1870.	1871.
Estimated population at the middle of the year.....	22,090,163	22,704,108
Number of schools, <i>i. e.</i> , of departments under separate head teachers, inspected:		
Receiving annual grants.....	14,565	15,494
Simply inspected.....	688	776
Total.....	15,253	16,210
Accommodation:		
In annual-grant schools.....	1,878,584	2,012,679
In simple-inspection schools.....	53,982	72,735
Total.....	1,932,566	2,085,414
Number of scholars in schools receiving annual grants:		
Present at examination:		
Day scholars.....	1,424,766	1,509,258
Evening scholars.....	77,918	86,279
Total.....	1,512,684	1,595,567
Average number attending:		
Day scholars.....	1,152,389	1,231,434
Evening scholars.....	73,375	88,457
Total.....	1,225,764	1,319,891
Number of scholars in schools simply inspected:		
Present at examination:		
Day scholars.....	39,117	48,959
Evening scholars.....	5	173
Total.....	39,122	49,167
Average number attending:		
Day scholars.....	16,592	24,656
Evening scholars.....	7
Total.....	16,599	24,656
Number of teachers:		
Certificated.....	12,467	13,195
Assistant.....	1,262	1,251
Pupil-teachers.....	14,304	16,941

A large part of this work is under the care of the established church and other religious organizations, the state doing but a small proportion. The first education grant, of £20,000, was made in 1833. In 1872 the grants were raised to £1,551,560, of which about one tenth was spent in administration and building. This grant was an increase over that of the preceding year of £512,936. The total amount of education grants from 1833 to 1872 has been £14,553,262. The subject of national education is of increasing interest in England. The

question of religion causes the chief difficulty. The rivalry of different religious organizations has stimulated them to great exertions for education, but a strong sentiment urges the separation of public education from all religious control. For a more complete account of the system of education in England, see EDUCATION.—The established religion is that of the church of England, which will be treated in a separate article. The dissenters constitute some of the most respectable religious bodies in the world. They consist of Presbyterians, Independents, Baptists, Friends, Methodists, Unitarians, Bible Christians, Moravians, and some others. The Presbyterians, Methodists, and Baptists are severally divided into a number of sects. The Roman Catholics are not numerous, but among them are many old and wealthy families. The Jews are few, but since July 23, 1858, when they were permitted to sit in parliament, they have enjoyed all civil rights.—The government is a limited hereditary monarchy, the supreme power being vested in a king or queen and ministry, and a parliament composed of lords and commons, the former sitting chiefly by hereditary right and the latter by popular election. A previous knowledge of English history being required for a comprehension of the changes and present state of the English constitution, we shall refer the reader for an account of the latter to the concluding part of this article. The following tables show the revenue and expenditure of the United Kingdom for the year ending March 31, 1873 :

REVENUE.

Customs.....	£21,033,000
Excise.....	25,755,000
Stamps.....	9,947,000
Land tax and house duty.....	2,337,000
Income tax.....	7,500,000
Post office.....	4,820,000
Telegraph service.....	1,015,000
Crown lands (net).....	375,000
Military and naval, extra receipts and proceeds of old stores sold.....	889,490
Amount received from the revenues of India on account of British troops serving in that country.....	996,373
Allowance out of profits of bank of England per act 24 Victoria, c. 3.....	138,578
Miscellaneous receipts.....	1,772,329
Gross income.....	£76,608,770

EXPENDITURES.

Debt:	
Interest and management of the permanent debt.....	£22,136,398
Terminable annuities.....	4,539,547
Interest of exchequer bills.....	128,912
	£26,804,852
Charges on consolidated fund:	
Civil list.....	£406,910
Annuities and pensions.....	303,139
Salaries and allowances.....	100,269
Courts of justice.....	644,657
Miscellaneous charges.....	108,239
Telegraph sinking fund.....	11,740
	1,574,954
Supply services:	
Army.....	£14,466,700
Navy.....	9,543,000
Army purchase commission.....	946,500
Miscellaneous civil services.....	10,175,185

Supply services, continued:	
Customs and inland revenue.....	2,504,302
Post office.....	2,634,130
Telegraph service.....	841,766
Packet service.....	1,133,058
	42,324,641
Total ordinary expenditure.....	£70,714,448
Army expenses provided for by annuities.....	808,000
Total expenditure.....	£71,022,448
Excess of income over total expenditure.....	£5,586,322

The public debt, March 31, 1873, was:

Funded.....	£726,584,423
Estimated capital of terminable annuities.....	53,358,550
Unfunded.....	4,829,100
Total.....	£784,972,108

The total debt at historical periods during the past century has been :

PERIODS.	Capital of debt.	Interest and management.
1775 } American war.....	£128,558,635	£4,471,571
1784 }	249,851,628	9,451,772
1793... Beginning of French wars.	239,350,148	9,208,495
1817 } Consolidation of English and Irish exchequers..	840,550,491	32,038,191
1836.....	787,638,516	29,143,517
1873.....	784,972,108	26,804,853

The army estimates for 1873-'4 called for a total expenditure of £14,416,000, and gave the regular army at 125,000 men, including 63,000 home forces; besides militia 139,000, yeomanry 15,000, volunteers 161,000, first reserve 10,000, and second reserve 20,000. The desertions from the regular forces in 1872 were 4,000. The navy estimates for 1873-'4 called for an expenditure of £9,704,985, and gave the following numbers of seamen and marines:

For the fleet:	
Seamen.....	34,000
Boys.....	7,500
	41,500
Marines.....	14,000
For the coast guard (ashore).....	4,300
Indian service.....	1,200
Total.....	61,000

The total naval force in September, 1872, was: steam vessels, including 60 iron-clads, 167 in commission and 197 in reserve and building; coast-guard tenders, 25; sailing vessels, 38 in commission and 106 in reserve and building; total tonnage, 677,883; number of guns 5,080. The government has fine dockyards at Deptford, Woolwich, Chatham, Sheerness, Portsmouth, Devonport, and Pembroke, a naval academy at Portsmouth, a military academy at Woolwich, and a military college at Sandhurst.—The judicial system of England until recently comprised four superior courts: the high court of chancery, the court of exchequer, the court of king's (or queen's) bench, and the court of common pleas. The court of king's bench was the supreme court of common law, and took cognizance of both civil and criminal causes, and to it could be removed by writ of error the judgments of all other English courts

of record. It consisted of a chief justice and four other justices. The court of common pleas likewise consisted of five justices, and took cognizance of civil cases between subjects. The court of exchequer consisted of a chief baron and four other barons; it was both a law and an equity court, trying all revenue questions and many other cases. The judges of these three courts were called the fifteen judges of England. In August, 1873, by an act to take effect in November, 1874, the superior courts of England were united into a supreme court of judicature, divided into two parts, a high court of justice and a court of appeal. The judges of the old courts are retained in the new one, which is presided over by the lord chancellor. The forms of administering justice are simplified, while the former distinction between law and equity is not recognized. The high court is divided into sections named after the old courts. The court of appeal consists of the chancellor, the two chief justices, the chief baron, and master of the rolls, with not exceeding nine ordinary judges. By act of parliament in 1846, and by several subsequent acts, a system of county courts has been formed, giving increased facilities for the prompt and inexpensive collection of small debts. The judges of these courts are appointed by the lord chancellor, and must not exceed 60 in number. Demands not exceeding £50 are brought before these courts, the judges of which determine all questions whether of law or fact, unless a jury be summoned, which is done at the request of either party. The number of jurymen is five. A court of general quarter sessions of the peace is held four times a year in every county, its jurisdiction extending to all felonies and trespasses, but the capital cases generally are remitted to the assize. The criminal code, which for a long time was excessively severe, has been greatly improved. The commitments and convictions from 1869 to 1873 were as follows:

YEARS.	COMMITTED.			Con- victed.
	Men.	Women.	Total.	
1869.....	15,722	3,596	19,318	14,340
1870.....	14,010	3,568	17,578	12,953
1871.....	12,640	3,629	16,269	11,946
1872.....	11,467	3,334	14,801	10,862

Most of the convicts sentenced for long terms of detention were formerly transported to penal colonies, or confined on board hulks, but prisons are now established at home capable of receiving all. There are in England 121 county, borough, and "liberty" prisons (*i. e.*, prisons for the districts so called). The commitments for 1872 to reformatory schools were 1,445; the number detained at the end of the year was 5,356, 4,322 males and 1,034 females. The average annual cost per head was, boys £18 19s. 9½*d.*, girls £17 16s. 3½*d.* There were also 2,050 commitments to industrial schools

schools in the year, and detained at the close of the year 7,120, 5,443 boys and 1,677 girls. The police force of England and Wales in 1870 was 26,441, and the cost of maintaining it during the year was £2,182,522.—The history of England begins shortly before the commencement of the Christian era, when Cæsar first invaded the island, landing near Deal or Walmer (55 B. C.). Britannia and Albion were the names by which it was known to the Romans. The inhabitants, called Britons, were of Celtic race, kindred to the Gauls. The Phœnicians had known the island, and so had the Carthaginians and Massilians; and all of them are supposed to have traded with it directly or indirectly, the Phœnicians especially, for tin. Yet at the time of Cæsar's invasion little was really known concerning the country, and for a long period afterward it was regarded as cut off from the rest of the world. He made little impression on it, and his invasion probably met with more resistance than is commonly supposed. Augustus proposed an expedition to Britain, but never attempted it. Caligula also threatened an invasion without executing it. Claudius began the work of real conquest, A. D. 43. During the next 40 years the conquest of south Britain was completed, many generals being employed, including Aulus Plautius, Vespasian, Suetonius Paulinus, and Agricola. The main divisions of the country were Britannia Romana, embracing England and Wales, which had been entirely subdued, and Britannia Barbara, which at first included all the country to the north of the wall of Hadrian, but later only what was to the north of the wall built by Antoninus, from the frith of Clyde to the frith of Forth. This region defied all the efforts of the Roman arms. The other was in a very flourishing condition, and at a later period was divided into five provinces, named Britannia Prima, Britannia Secunda, Maxima Cæsariensis, Maxima Flaviensis, and Valentia. Christianity had been early introduced, and before the close of the 3d century a regular hierarchy was established. The country suffered with the rest of the empire from the invasions of barbarians, and was abandoned by the Romans before the middle of the 5th century. The Britons then became independent, and displayed much energy and spirit in contending with the invaders. They were less successful in their endeavors to establish a body politic, and the island was distracted by contentions and civil wars. The disturbed state of the country was favorable to the incursions of the Picts and Scots, tribes like the Britons of Celtic origin, when a few Saxons, said to have been exiles, arrived in the isle of Thanet. They were but 300, and were led by two brothers commonly called Hengist and Horsa. They were, it is probable, on a piratical excursion. The story that they came by invitation probably originated in the fact that other Saxons were subsequently invited to Britain. The British chiefs hired their visitors as soldiers, according

to a not uncommon custom. They chastised the Scottish invaders, and when the Saxon leaders proposed sending for more of their countrymen, in order that their defensive measures might be more extensive, the proposition was readily received, and numbers of Saxons, Angles, and Jutes arrived in the country. At first these strangers proved good friends to the Britons, but when they had conquered the other barbarians they took Britain for their reward. This, however, was not effected without a bloody contest, in which the Britons evinced great bravery, and at one time are said to have expelled their false allies. The history of these times is little better than fable, and the very names of Hengist and Horsa are perhaps as mythical as those of Romulus and Remus. The most that is known is, that certain Germanic invaders subdued the greater part of Britain, driving the Celtic natives into Wales and adjoining parts, and laid the foundation of that England which has occupied so large a space in the history of the world for so many centuries. These invaders appear to have belonged substantially to one race, but they had strong points of difference, which were particularly prominent as between Saxons and Angles. One effect of this German conquest was to cause Britain to revert to heathenism; but in the pontificate of Gregory the Great the work of Saxon conversion commenced, under the guidance of the monk Augustin. Seven independent kingdoms, jointly called the heptarchy, had gradually been formed by the conquerors since the year 449, viz.: Kent, Sussex, Wessex, Essex, East Anglia, Mercia, and Northumbria. The last consisted of the two prior kingdoms of Deira and Bernicia, united by King Ethelfrid in 593. There was almost constant war among them, and two or more were frequently united under one head (in which case the monarch of the united kingdoms was called a *bretwalda*), until finally Egbert, king of Wessex, about 827, conquered them all, and first styled himself king of England. In his reign the Northmen first appeared in force in England; and it shows the vitality of the old British race that numbers of them joined the invaders. There had been previous attacks, but this was the most serious; it was unsuccessful, and the Britons who had risen were punished severely. These invasions were constantly renewed, the Northmen and Danes being the terror of all peoples who could be reached from the sea. Large portions of England fell into their hands. Much of Alfred's reign (871-901) was passed in contests with them. The fortune of these wars was various, but even the victories of the Anglo-Saxons cost them dear; yet it is probable that the general result was good, and that the infusion of new blood into England prevented the country from degenerating, and gave to it a new life. Much of what is called Saxon is of Danish origin; but the Danes and Saxons were substantially of the same race, the differ-

ences being in favor of the former. A Danish dynasty was established in the early part of the 11th century, and the name of Canute, or Knut, is high on the list of England's sovereigns. The Saxon dynasty was restored in 1042, in the person of Edward the Confessor, on whose death the throne was conferred on Harold, son of Earl Godwin, a great Saxon statesman. But an event was impending over England which was to color her history for ever. The Normans, descendants of those Northmen who had settled in Neustria (N. W. France) and given it the name of Normandy, had obtained considerable influence in England in the Confessor's time, and were indeed the leading race of the West. William, duke of Normandy, claimed the throne of England through his great-aunt Emma, mother of Edward the Confessor; the latter favored his claim, although compelled to leave the crown to Harold. Neither William nor Harold had a strictly legitimate right to the throne, but Harold had the support of the English nation, and William assembled a powerful army to enforce his claim. The support the duke received from his own subjects was reluctantly given, but the promises of spoil attracted many adventurers from different parts of Europe, so that he was enabled to land 60,000 men in England. Harold, who had just defeated an army of Norwegian invaders, met the Normans at Hastings, where he lost his life and his kingdom, Oct. 14, 1066. William's victory was complete, and the Normans and other adventurers soon became masters of all England. Saxons and Danes were involved in common slavery. The victor introduced the feudal system into England. It is probable that the extent of the Norman spoliation has been much exaggerated, but that the natives were reduced to a state of political bondage admits of no doubt whatever. The very name of Englishman was made odious. A foreign rule was established over England, and it was not until seven generations had passed away that the distinction between Norman and Saxon was nearly obliterated. It did not disappear altogether till a much later period, but it ceased to influence legislation about the end of the 13th century. The Norman line gave three sovereigns to England: William I., William II., and Henry I. The death of the last, in 1135, was followed by the reign of Stephen of Blois, his nephew, and by the wars between that king and the adherents of the old dynasty. Henry I. left an only daughter, Matilda, married first to the emperor of Germany, and then to Geoffrey, earl of Anjou, by whom she had that prince who became Henry II. of England in 1154. England suffered terribly in the contest between Stephen and Matilda, the rightful heiress to the crown, who was supported by a powerful party. Henry II. became king in consequence of an arrangement with Stephen, who had lost his only son Eustace, but the treaty was really the work of the

barons, who had risen to high power during Stephen's reign. The young king was the founder of the royal family of Plantagenet, which held the English throne 330 years. He had Saxon blood, his great-grandmother being a Saxon princess, descended from Alfred. There have been few abler monarchs than Henry II. He was duke of Normandy and count of Anjou, and, having married Eleanor of Aquitaine, was also duke of Aquitaine and count of Poitou. Maine belonged to him. He undertook the conquest of Ireland. Had it not been for his dispute with Becket, and domestic troubles at a later period, he might apparently have conquered the whole of France. The crusades, too, were prejudicial to his interests. He died in 1189, and was succeeded by Richard I. (*Cœur de Lion*). The English are proud of this chivalrous king, yet he was a Frenchman, could not speak the language of the island people, and kept out of England whenever he could. His brother and successor, John, who ascended the throne in 1199, was one of the weakest and most wicked of kings; he is one of the few men, eminent either from talent or position, who, after having been long regarded as monsters, have had nothing said in their favor by modern writers. His French rival, Philip Augustus, was an able statesman. Their contests were ruinous to John as a continental sovereign. Normandy, Brittany, and Anjou were lost, and the English Plantagenet had little more than England for his dominion. His continental possessions were all to the south of the Loire. The insular Normans were thus separated from the continental Normans, and were compelled to have the same interests with the mass of the people. From this came the series of events that led to the concession of the great charter, June 15, 1215. John was involved in disputes with Pope Innocent III., to whom he afterward resigned his kingdom, and received it back on terms which made him a vassal. In a contest with France his troops shared in the loss of the battle of Bovines. The barons called Louis, the son of the king of France, to their aid, and he at first was successful; but evincing a partiality for his countrymen, he lost ground, many of his first supporters joining John, who was about to fight him, when he died, Oct. 19, 1216. He was succeeded by his eldest son, Henry III., then nine years old. The government was conferred on the earl of Pembroke, who compelled the French to make peace and to leave the country. On Pembroke's death power passed to the hands of Hubert de Burgh and the bishop of Winchester, but the former was soon compelled to resign it. The reign of Henry III. is the longest in English history save that of George III., and it was passed in constant troubles. The favor shown to foreigners caused much irritation. There were frequent disputes with the barons, which led to important consequences. Under the lead of Simon de Montfort, earl of Leices-

ter, the barons defeated the king at Lewes in 1264, and took him captive; and under Leicester's rule, the first English parliament in the modern sense was assembled in 1265. But in the same year the party of Leicester was overthrown, and the royal authority seemed firmly established. Prince Edward, the son of Henry, who had effected this, set out to join the last crusade. Henry's weakness encouraged his enemies, and the country was relapsing into confusion, when he died in 1272. Edward I. ascended the throne without opposition, and proved himself a good sovereign, founding permanent legal institutions which have ever since been spoken of with respect. He conquered Wales, annexed it to England, and conferred the title of prince of Wales on his son and heir, which has ever since been borne by the eldest son of the sovereign of England. He sought to conquer Scotland, and at one time appeared to have succeeded; but the resistance of the Scotch, first under Wallace, then under Comyn and Fraser, and finally under Bruce, saved their country from becoming an English dependency. Edward was involved in a war with France, which had seized Guienne, one of the few remaining possessions of the English on the continent, but it was restored under papal mediation. His wars made him dependent on parliament, the power of which was much increased in his reign, the commons first sitting in a separate chamber in 1295. This has been considered the first session of the commons, though perhaps that distinction belongs to the parliament summoned by Simon de Montfort under Henry III. Edward violated the great charter, and for a time showed every disposition to reign arbitrarily; but the opposition he experienced was not to be overcome, and he gave way before it. While marching to meet Bruce in Scotland, he died, July 7, 1307. His successor, Edward II., was unable to comprehend or to accomplish his father's designs. He was governed by favorites, whose insolence provoked the barons, by whom the chief favorite, Gaveston, was put to death in 1312. The king was induced to lead a great army to Scotland in 1314, which was completely defeated at Bannockburn, an event that established the Scottish nation and the throne of Bruce. At the instance of Edward's queen, Isabella of France, parliament deposed the king, who was soon afterward murdered, September, 1327. The government was now nominally in the hands of Edward III., a boy of 15, but in reality it was wielded by Isabella and Roger Mortimer, her paramour. These rulers were unpopular, and their unpopularity was increased by a treaty which they made with Scotland in 1328, renouncing all claim to superiority over that country. Mortimer was able and unscrupulous, and the young king conspired against him. The queen mother and her lover were seized, and the latter was executed. The reign of Edward III. is one of the most brilliant in Eng-

lish history. He repressed the lawless men who had had their way during his father's reign. Aiding Balliol in an attempt to obtain the crown of Scotland, he won over the Scotch the victory of Halidon Hill, July 19, 1333. He set up a claim to the crown of France, in right of his mother, which led to that rivalry of France and England which has endured to this day. He had numerous allies on the continent, and he led an army into France in 1338, which accomplished nothing. The great naval victory of Sluis was gained by the English in 1340. Troubles with parliament and want of money impeded the war, and it was not till 1346 that the battle of Crécy was won by the English. Calais was afterward taken, and the king then made a truce with the French. While he was absent, an army raised by his wife defeated the Scotch at the battle of Neville's Cross, and captured their king, David Bruce. A naval war with the Spaniards followed, and the latter were defeated in a great battle. The pestilence that ravaged the world in the 14th century appeared in England in 1349. The renewal of the war with France led to the battle of Poitiers in 1356, in which Edward, prince of Wales, known as the Black Prince, defeated King John of France, and made him prisoner. In 1359 Edward III. again invaded France, and besieged Rheims, because he wished to be crowned king there. The next year peace was made between the two countries, Edward renouncing all claim to the French crown, but receiving large portions of French territory and an immense sum of money. The French king, finding himself unable to fulfil the terms of the treaty, went back to England a prisoner, and there died. The prince of Wales, from Guienne, interfered in the affairs of Spain, and won the battle of Najera in 1367, in behalf of Pedro the Cruel, and over the French, who under Du Guesclin were aiding Henry of Trastamare. The expense of this war made the prince unpopular, and his last days formed a miserable contrast with his early career. He died in 1376, a year before the death of his father. The latter years of the king were also embittered by failure in France, and by disputes with parliament. Much was done in this reign toward the development of English industry, and some constitutional questions were settled. The new king, Richard II., son of the Black Prince, was only 11 years old, and a regency was appointed. The war with France languished. The peasantry, headed by Wat Tyler, rose in rebellion. The young king showed both tact and courage on this occasion, and gave greater promise of ability than was justified by his career. A war with Scotland led to no results. The ambition of the king's uncle, the duke of Gloucester, caused internal troubles. The king wasted on frivolous pleasures money that had been granted him for other purposes, and he completed his unpopularity by making a long truce with France, and by marrying the daughter of

Charles VI., a child of seven years. Gloucester sought to avail himself of this unpopularity, but was seized, imprisoned, and put to death, and his party was destroyed. Parliament stood firmly by the king. Two of his supporters were the dukes of Hereford and of Norfolk, and they quarrelling, the king banished them both, the first for ten years, and the second for life. Hereford was son of John of Gaunt, the duke of Lancaster, and cousin of the king, and when on his father's death the king seized his cousin's estates, the new duke of Lancaster returned to England, and rapidly levied a force that placed him at the head of the country. He compelled the king to resign the crown, and assembled a parliament, which made him king on the ground of his descent from Henry III. According to the received ideas of succession, he had no claim to the throne, which, falling Richard and heirs of his body, belonged to the earl of March, descended from the duke of Clarence, third son of Edward III., the new king being son of Edward's fourth son. The reign of Henry IV. began Sept. 30, 1399. Richard was imprisoned and is supposed to have been murdered in Pontefract castle, but nothing is certainly known of his fate. Henry's reign was one of much interest. The followers of Wycliffe had become very numerous, and the king's father, John of Gaunt, had supported Wycliffe; but the son proved a firm adherent of the church of Rome, and consented to an act for the punishment of heretics passed in 1401, and under which much cruelty was perpetrated for two centuries. The Lancastrian dynasty, by allying itself with the church, postponed the reformation for four generations. The reign of Henry IV. was short, but eventful. In a war with Scotland, the English won the victory of Homildon Hill. The rebellion of Glendower in Wales was successful for many years, and that chief was never formally subdued, though finally forced to remain quiet. A rebellion headed by the earl of Northumberland broke out in 1403, but the victory of the king at Shrewsbury established his power. Other rebellions followed this, and the conspiracies were numerous. The French had insulted the English frequently, and Henry IV. was on the point of renewing the war, when illness compelled him to refrain; and soon after he died, March 20, 1413. His son and successor, Henry V., put down the Lollards with a vigorous hand, and renewed the war with France. In the summer of 1415 he reduced Harfleur. The battle of Agincourt, Oct. 25, 1415, was won by the English against great odds. The war was continued, and in 1420 it was settled by a treaty that Henry V. should marry Catharine, one of the daughters of Charles VI., and become heir to that king. Fortunately for England, which by its success would have been probably reduced to the condition of a province of France, this plan failed. Henry died Aug. 31, 1422, when apparently about to realize his scheme. He left but one child, a boy of nine months, who

became Henry VI., and was soon the king of a large part of France, his French grandfather dying soon after his father. The king's uncle, the duke of Bedford, carried on the war, and the English were mostly victorious over the French and their Scotch allies. A variety of events, however, among which the exploits of Joan of Arc are the most remarkable, led to a change in the fortunes of the contest, and the French had in 1451 recovered all their country except Calais and two other small places. Henry VI. proved to be a man of much amiability, but deficient in intellect and vigor. During his minority the court was the scene of intrigues and contentions; and when he had arrived at manhood, and married Margaret of Anjou, daughter of René, titular king of Sicily, Naples, and Jerusalem, that able princess became the real head of the state. The conflicts of parties were increased in fierceness, partly from the throwing of so many public men back upon England, who had lost all they had seized in France. That contest which is known as the war of the roses, or the contentions of the houses of York and Lancaster for the crown of England, commenced about 1452. Richard, duke of York, a descendant of the third son of Edward III., was the legitimate heir to the throne. Had Henry VI. been an able monarch, Richard's claims would have been of little practical importance; but the weakness of the king and the fierceness of the party contests united to concentrate men's attention upon the duke, who had many strong points of character, and had served his country well in France and Ireland. He had married Cecily Neville, daughter of the earl of Westmoreland, a near connection of the earls of Salisbury and Warwick, two of the greatest nobles of the realm. The duke expected to succeed quietly to the crown on the king's death, as Henry had no children for many years after his marriage; but in 1453 Prince Edward was born. The king was reduced by illness to a state of imbecility, and York was made protector; but when Henry in 1455 recovered his intellect, he resumed power, and showed such favor to the duke's enemies that the Yorkists assumed arms, and a civil war began which did not fully end until 40 years later. The first battle was fought at St. Albans, May 22, 1455, and was won by the Yorkists, or party of the white rose. The king was now in their power, and acceded to all the demands of York, who became protector again on the return of Henry's illness. The queen was less submissive, and nearly succeeded in her attempts to destroy the opposition chiefs. War was resumed in 1459, with various fortune. After the battle of Northampton, July 10, 1460, it was arranged that Henry should remain king for life, but that York should succeed him. Margaret resisted, and on Dec. 30 defeated the Yorkists at Wakefield. York and his young son, the earl of Rutland, and his chief supporter, Salisbury, were put to death. The

Yorkist claim now passed to Edward, earl of March, the duke's eldest son, a youth of 19, superior to his father in intellectual qualities, but his inferior in virtue and humanity. Edward marched against one of the Lancastrian armies and defeated it, and then proceeded to London, where the people and some of the parliament acknowledged his claims. He was proclaimed king, March 4, 1461; and so prompt were his movements that he met the Lancastrian army at Towton, a few miles from York, the 29th of the same month (Palm Sunday); 100,000 men joined battle, and after the most sanguinary conflict that ever occurred on English ground, victory declared for Edward IV. Margaret renewed the contest with French and Scottish aid, but was beaten at Hexham, May 15, 1464. Henry fell into his rival's hands, and was imprisoned in the tower. The power of the Yorkists being established, they fell to quarrelling among themselves. The Nevilles, at whose head stood the earl of Warwick, claimed more than the king could grant, and so became enemies of the royal house. The king's marriage with Elizabeth Woodville, widow of Sir John Grey, gave offence to Warwick. The duke of Clarence, a brother of the king, married the eldest daughter of Warwick, to the disgust of the monarch. In 1469 the Nevilles headed a rebellion, being aided by Clarence, and the king at one time was their prisoner. Released from confinement, Edward put down another rebellion, and conferred high favors on Clarence and Warwick; but the quarrel was renewed, and failing to seize the king, the rebel chiefs fled to France, where Warwick, under the mediation of Louis XI., joined the party of Margaret of Anjou. Landing in England, and proclaiming Henry VI. king, Warwick was everywhere successful, and Edward fled to Holland; but in a few months he returned, and was as successful as Warwick had been. In four weeks he entered London, having been joined by his brother Clarence. The battle of Barnet was fought April 14, 1471, and the Lancastrians were defeated, Warwick and his brother Montague falling on the field. On May 4 Edward again defeated the Lancastrians at Tewkesbury, Prince Edward, son of Henry VI., being taken prisoner, and at once put to death. Margaret of Anjou was made prisoner, and sent to the tower, where her husband perished soon afterward. Edward was no more disturbed by the Lancastrians, but the dissensions at his court caused him great trouble. His brother Clarence he put to death. He invaded France at the head of a large force, but Louis XI. bought peace of him, and he returned to England. He died in 1483. His successor, Edward V., was not quite 13 years old. The court was divided into two parties, the one consisting of the relatives of the young king on the maternal side, and the other of the old nobility. Richard, duke of Gloucester, the king's uncle, an able and ambitious prince,

seized the reins of government, was made protector, put to death several of the monarch's relatives and supporters, and finally made himself king. Edward V. and his brother, the duke of York, were placed in confinement, and soon disappeared, the general belief being that they were murdered by Richard's orders. The reign of Richard III. was brief, and much disturbed by conspiracies; he had offended the Yorkists, and had not conciliated the Lancastrians. A coalition was formed against him, at the head of which stood the earl of Richmond, who was the great-great-grandson of John of Gaunt, founder of the house of Lancaster, being descended from the earl of Somerset, son of that prince by Catharine Swynford, his mistress. Somerset had been legitimated by parliament, but cut off from the line of succession to the crown. On his father's side Richmond belonged to the Welsh family of Tudor, his grandfather, Owen Tudor, having married Catharine of Valois, widow of Henry V. of England. Thus Richmond had no legitimate claim to the throne; but party exigencies overcame everything, and to satisfy the Yorkists it was agreed that Richmond should marry Elizabeth, eldest daughter of Edward IV. The first effort of the conspirators failed, and the duke of Buckingham, the chief of them in England, was beheaded. In 1485 they were more successful. Richmond landed in Wales at the head of a small force, marched into England, encountered Richard at Bosworth, Aug. 22, and defeated him, the king falling in the battle. The crown that he wore in the action was placed on the head of Richmond, who was hailed as Henry VII. This monarch, first of the Tudor line, bore himself as chief of the Lancastrian party, and depressed the Yorkists whenever he could do so, though he felt himself compelled to marry the princess Elizabeth. His reign was disturbed by many conspiracies, and by the appearance of pretenders to the crown. The first of these was Lambert Simnel, who personated the earl of Warwick, son of the last duke of Clarence, and undoubted heir to the crown, failing children of Edward IV. The Irish supported this pretender, who was the son of an English baker, and he was aided by the duchess dowager of Burgundy, a sister of Edward IV., and notorious for her hatred of Henry VII. At the head of a miscellaneous force of Irish and foreign soldiers, the Yorkist leaders landed in England, and had they received any considerable English support would probably have succeeded; but they were left to fight unaided, and were totally defeated at Stoke, June 16, 1487. Among the slain was the earl of Lincoln, next to Warwick the chief member of the house of York. Simnel was taken prisoner and made a scullion in the king's kitchen. Another pretender was Perkin Warbeck, said to have been the son of a Tournay trader, but who claimed to be Richard Plantagenet, duke of York, second son of Edward IV., a claim which has

found strong defenders. Henry regarded him as a much more important character than Simnel, and foreign potentates treated him as if they believed in his claim. James IV. of Scotland gave him one of his relatives in marriage, and marched an army into England to aid him. But all his efforts failed. A Cornish insurrection was put down by the king, at the battle of Blackheath; yet when the pretender entered Cornwall he was regarded as king, was joined by a large force, and laid siege to Exeter. On the approach of the royal army, however, he fled, and subsequently surrendered on condition that his life should be spared. Flying a second time, he again gave himself up on the same terms, but was set in the stocks, and made to read a confession that he was an impostor. Consigned to the tower, he sought to escape, and was hanged at Tyburn (1499). Henry at the same time caused the earl of Warwick, the last survivor of the legitimate male descendants of Edward III., to be put to death, on a groundless charge of conspiracy with Perkin. With these proceedings closed the contest between the houses of York and Lancaster, in the complete prostration of the former, though the latter was represented by an illegitimate member, who was not even descended from Henry IV., the founder of Lancastrian royalty. The last years of Henry VII. were more peaceably passed, and he became a powerful sovereign at home, while his influence was great abroad. Under him England entered upon her career of maritime discovery. His master passion was avarice. He pretended to make war on France, but only that he might obtain money from his subjects, and then sold peace to the French monarch. He depressed the power of the high nobility in various ways. The law that no man should be held guilty of treason for adhering to the king *de facto* was passed in his reign. He died April 21, 1509. Henry VIII., his successor, was his second son, the first, Arthur, having died before his father. Arthur had married the princess Catharine of Aragon, daughter of Ferdinand and Isabella, and on his death his father had procured a dispensation from the pope allowing the marriage of Catharine and his second son, which was not solemnized until after the accession of Henry VIII. He was frequently engaged in hostilities with foreign countries, and the great victory of Flodden was won by one of his generals over James IV. of Scotland, husband of his sister Margaret. His policy was the result of his passions. That he was troubled concerning his marriage with his brother's widow, after that marriage failed to produce sons that could arrive at maturity, is easily believed, as he was singularly superstitious; but it required his passion for Anne Boleyn to give his scruples much force. Had the court of Rome aided him to a divorce, he would have remained a Catholic; but that court refusing this, he threw off his allegiance

to the pope, and became head of the church in England. He was six times married, and two of his wives were beheaded and two were repudiated. Much that was severe in Henry's treatment of his wives has been attributed to his desire to have heirs, the wars of the roses having made English sovereigns, statesmen, and people very sensitive on the subject of the succession. Henry interfered much in continental politics, and the European balance-of-power theory dates from his time. In his reign the scaffold was occupied by victims from every class of society, the number of whom, however, has been considerably exaggerated. The highest classes were the greatest sufferers, the king being impartial in the selection of his victims. He died Jan. 28, 1547, and was succeeded by his only son Edward VI., whose mother was Jane Seymour, Henry's third wife. Edward was in his 10th year, and the government was placed in the hands of a council of regency, the principal members of which were the earl of Hertford, the king's uncle, soon created duke of Somerset and protector, and Archbishop Cranmer. In this reign the church of England was established, and the nation placed on the Protestant side in the struggle then going on in Europe. In the contests for power that took place at court, Somerset was finally worsted, and then beheaded. Dudley, duke of Northumberland, into whose hands all power passed, caused his fourth son, Lord Guildford Dudley, to marry Lady Jane Grey, great-granddaughter of Henry VII.; and when Edward VI. died, July 6, 1553, the duke made Lady Jane queen, to whom Edward had been persuaded to bequeath the crown. Her reign lasted but ten days, and her party was quickly dispersed. Mary, eldest daughter of Henry VIII., ascended the throne, and behaved mercifully toward most of those who had sought to prevent her succession. Northumberland and others were executed, but Lady Jane and her husband were spared till the next year, when they were executed, in consequence of the lady's father, the duke of Suffolk, having taken part in Wyatt's rebellion. Suffolk also was executed. Mary effected a reconciliation with Rome, and gave her hand to Philip II. of Spain. This marriage led to war between England and France, and an English army joined the Spanish force that invaded France, and took part in the battle of St. Quentin. The French succeeded in an attack on Calais, the loss of which shortened Mary's life. She was a devout Catholic, and caused Cranmer, Latimer, Ridley, and about 300 other Protestants, to be burned. Her death, which occurred Nov. 17, 1558, left the throne to Elizabeth, who, somewhat against her own inclinations, sided with the Protestants for obvious reasons of policy. Her reign, which lasted nearly 45 years, is one of the most brilliant in English history. Sagacious in the selection of her counsellors, though her occasional folly gave them great trouble, she triumphed over her en-

emies, and raised her kingdom to the first place in Europe. She ruled over Scotland in fact, and put the sovereign of that country to death after having held her in captivity nearly 19 years. The Huguenots of France and Henry IV. received aid from her, and but for the assistance which she gave the Dutch they would have sunk under the power of Spain. She invited the Turks to join her in attacking the pope and Philip II.; and over both those potentates she achieved a great triumph in 1588, when the Spanish armada was destroyed. Some of the greatest names in the literature of England belong to the Elizabethan age. The enterprise of Englishmen led them to circumnavigate the globe, to attempt colonization, to extend commerce, and to commence the trade with India. Elizabeth had not much to do directly with these things, but she was the central figure of a great nation in a great age, and all that was accomplished by her subjects increased the splendor of her glory. She died March 24, 1603, and with her terminated the Tudor dynasty, after an existence of nearly 118 years. She was succeeded by James VI. of Scotland, the son of her victim Mary Stuart, and first king of England of the Stuart line, who inherited the English crown in virtue of his descent from Margaret Tudor, eldest daughter of Henry VII., who had married his great-grandfather, James IV. The new king was hailed with much satisfaction by the English. The question of the succession to the throne had been one of vital interest since the successive wives of Henry VIII. had proved so unfruitful. Rulers and people alike had been deeply moved by the danger of a disputed succession, and from the death of Edward VI. to that of Elizabeth only two women of the main line were in existence, and for 44 years only one woman, Elizabeth herself. The anxiety that was felt for the marriage of Elizabeth was owing to this dread; so that when the sceptre passed quietly to the hand of a monarch who was descended from their ancient kings, who was not yet at the period of middle life, and who was the father of several children, a weight was taken from the English mind. Had James been a man of common sense, he might have preserved this popularity, and laid deep the foundations of his dynasty; but he was a pedant and a tyrant, without the courage which is necessary to maintain a tyranny. His person, his manners, and his actions were all against him; and before he had reached London his popularity began to decline, and was quickly exhausted. He commenced that course of policy which was destined to cause his house to become extinct in exile. The divine right of kings, so abhorrent to reason and to English ideas of government, was the basis of his conduct. He perpetually claimed higher power than any Plantagenet or Tudor, but he invariably abandoned his ground when he was resisted. His first parliament, 1604, in reply to his assertion that all their priv-

ileges were derived from him, asserted in full, and in the plainest language, all those principles for which the English constitutionalists contended as facts not to be questioned. Then began that civil contest which lasted down to 1689 in full force, and which was not utterly at an end till 1746. The foreign policy of James was as vicious as his home policy, and England became of less account in the European world than a second-rate German or Italian principality. James I. died in 1625, and was succeeded by his son Charles I., a monarch who had some elegant tastes, but who apparently could not conceive of any obligations on the part of a king to his subjects. He did not put forward his pretensions so offensively as his father, but he adhered to them with a courage and a tenacity that were utterly unknown to James. He set deliberately to work to introduce into England the system of government that prevailed in France, to do in England and Scotland what the Austro-Burgundian princes had done in Castile and Aragon. He had been educated in England from his early childhood, had good faculties, and had by his assent to the petition of right expressly agreed not to rule arbitrarily, for a full and solid consideration paid into his hands. Yet for 11 years (1629-40) he called no parliament, and England was ruled as despotically as France; and had all his instruments been prudent and able men, it is possible he would have succeeded in his design. His chief instruments were Wentworth, afterward earl of Strafford, and Laud, archbishop of Canterbury; the former one of the ablest men in an age singularly prolific in able men; the latter equally distinguished for his narrowness of mind. These two men seem to have been associated only that the wisdom of the one might be confounded by the folly of the other. Laud gave precedence to ecclesiastical tyranny, whereas Wentworth, if he had had entire management of affairs, would have established political despotism, whence religious uniformity would soon have followed. It is very doubtful whether the people could have been stirred up to the fighting point if their religious sentiments had remained without serious disturbance until their political rights had been totally subverted. Laud sought to fasten the English church polity on Scotland, which was met by deep and determined resistance on the part of the Scotch. War between the Scotch people and the English government followed, and Charles was compelled to call a parliament, April, 1640. Thus were all Wentworth's sagacious plans set at naught. The parliament, known in history as the short parliament, lasted but a few days, when it was dissolved. Six months later assembled the famous long parliament, which the king's necessity forced him to call. This parliament punished the king's tools, and forced him to admit that it should not be dissolved without its own consent. It then proceeded to divest the king of much of his power, demanding

among other things the control of the militia. The parliamentary party went beyond the limits of the constitution in their desire to preserve the constitution; but their justification is to be found in the purpose and acts of the king, and in his incurable falsehood. The political leaders of 1640-42 never counted upon the king's death or deposition, and at no time was it out of his power to have reigned in strength and peace, on the sole condition that he should rule as a constitutional sovereign. It was natural that Charles should refuse to part with power that was legally his; and it was equally natural that the parliament should refuse to allow it to remain in his hands. Both parties appealed to arms, and what is known as the great civil war began in the latter part of 1642. At first fortune favored the king, but his wrong-headedness rendered him unable to profit therefrom. Gradually the radical party in parliament gained strength, and, under the lead of Vane, Cromwell, and others, rose to power. Cromwell was everywhere victorious in the field. Parliament was "purged" of all who showed any disposition to treat with the king. The army became the source of all power. The king was tried, condemned, and executed. Ireland was conquered by Cromwell, who was almost equally successful in Scotland. The battle of Worcester, Sept. 3, 1651, crushed the royalists for nearly nine years. In 1653 Cromwell dissolved the parliament by force, and was master of England for five years, ruling the country more wisely than it had been ruled by Charles or James, but still with an iron hand. He would have ruled constitutionally if he could, but by him the English would not be so ruled. He wished to become king, but this the army would not allow, for it was composed of sincere republicans. Yet England then occupied the highest place she had ever known in the world's estimation; one in striking contrast with that which she had held during the 40 years of the rule of James I. and Charles I. The subjection of Ireland had now been consummated. After Cromwell's death, in 1658, dissensions broke out, and the military and civil republicans quarrelled. Richard, the son of the great protector, who had succeeded his father, but had little ability, resigned, and thus was prepared the way for the restoration of the Stuarts, effected by Gen. Monk in 1660. The reign of Charles II. dates in fact from that year (May 29, when he entered London), though in law it dates from the day of his father's decapitation. The change was prodigious. The austere Puritans were succeeded by profligate cavaliers. The Puritans had insisted upon ruling the nation into righteousness, and had caused that reaction which ended in the foulest licentiousness. Many of the reforms effected by the long parliament remained permanent. That body had swept away the court of star chamber, the high commission court, and the council of the north, all tremendous instruments of royal tyranny, and not one of these

was it possible to revive. The nation had gone forward, and could not go backward, even under the reaction which caused sensible men to welcome back the profligate king. Had Charles been ambitious, he might have accomplished what his grandfather, his father, and after him his brother were unable to do; he might have established despotism in England, at least for a time. But, though one of the ablest members of his family, he was singularly destitute of those feelings which ordinarily are found in monarchs. He loved his ease above all things, and if he could get pleasantly through the 24 hours, he was quite willing that other men should do so. He had many of those qualities which are popularly attributed to his grandfather, Henry IV. of France; but he probably laughed at his ancestor's daring in the field. His vices were of the popular kind, and such as men are ready to forgive in kings. From the 11th to the 30th year of his age his life had been passed amid civil disputes, wars, wanderings, and intrigues, and in poverty; and he had contracted from this experience a horror of everything like danger or business. Happen what might, he is reported to have said, he would not again go on his travels. From the personal selfishness of this easy voluptuary England derived almost as much good as from the tyranny of John or the cowardice of James I. He was content to rule as much through parliament as could be expected from a monarch under such little restraint. Several times, when persuaded to venture upon some despotic act, he was ready to give way when he found the opposition resolute. He retreated from the ground assumed in his declaration of indulgence, and so weakened the royal power. His popularity soon declined, mainly on account of his foreign policy. England's honor, it may be said, was gibbeted with Cromwell's body at Tyburn. An unnecessary war with the Dutch produced much disgrace. The triple alliance with Sweden and Holland for a brief interval stayed the course of Louis XIV., but this was the solitary act of the kind that reflects honor on this reign. The king soon became the tool and pensioner of France. His forces assisted in the war on Holland made by Louis XIV. The unpopularity of this course, and the internal misgovernment of the cabal ministry, created a great change in English opinion, and finally assistance was sent to the Dutch. The peace of 1678 was followed by the excitement caused by the alleged popish plot, and for a time the king was almost as unpopular as his father had been in 1640. Parliament after parliament was elected, met, set itself in decided opposition to the government, and was dissolved. The leading object of the opposition was the exclusion of the duke of York, Charles's brother, from the line of succession; and even to this the king would finally have consented rather than fight. But a reaction set in and saved him from the last disgrace; and when the Oxford parliament was dissolved, in

1681, the king found himself hardly less powerful than he had been in 1660. He never called another parliament, but was able to govern without one. The conspiracies that were formed by the whigs (the names of whig and tory had their definite political commencement in 1680) were detected, and many of the conspirators were punished. Others, men of whom the government wished to be rid, such as Russell and Sidney, were executed. Few kings have been more powerful than Charles II. was during the last three years of his reign, yet some marked advantages had been obtained by the constitutionalists, which have endured. The *habeas corpus* act of 1679 was among the greatest triumphs of the liberal party, not only in itself, but because it furnished a point of union between whigs and tories; for in the next reign it was found that the tories, even when most servilely loyal, could not be prevailed upon to repeal that act. Charles II. died suddenly in February, 1685. His brother James II. came to the throne without opposition, and for a brief period was popular. Though an open and avowed Catholic, he was beloved by the priesthood of the church of England, which indeed had saved his inheritance in the days of the exclusion bill. Had he been content with persecuting the dissenters and whigs, and with destroying much of the civil liberty of his subjects, it is not unlikely that he would have made himself as powerful as Henry VIII. had been; but he wished to reestablish the ascendancy of his own church, which could not be done without overthrowing the Anglican church, and despoiling the aristocracy of much of their property; and thus he united church, aristocracy, and all the intelligent part of the people against him. The parliament which he summoned was most servile, but it could not satisfy the king. He was bent on the establishment of a despotism, and the destruction of the constitution in church and state. He punished Monmouth's rebellion with a vindictiveness to which there are few parallels in history. The king prorogued parliament in November, 1685, and that body never met again. For three years he governed despotically, and a perpetual contest was waged between him and his people; and the vigor displayed on the popular side shows how well established was the English constitution. The king at first sought the aid of the church against the dissenters, and received it until the church found he meant its own destruction, together with that of all other forms of Protestantism, when it revolted, in spite of its passive obedience doctrines. He then sought an alliance with the dissenters against the church, and though some of them were ready to aid him, the great majority remained true to the constitution. By the autumn of 1688 the king was opposed by almost all classes of his subjects, and could not procure the services of even third-rate lawyers in an age proverbial for the baseness of its legal men. William,

prince of Orange, had watched the contest closely. He was the king's nephew, son of his sister Mary, and had married the king's eldest daughter Mary, heir apparent to the British crown. It is not probable that he cared much for the liberties of England, for he was the chief of that party in Holland which was opposed to the existing constitution, a polity in its spirit not unlike to that of England; but he was firmly opposed to Louis XIV., and desired to have the aid of England in thwarting his schemes; and James was the pensioner and ally of Louis, and so would remain so long as he should persist in governing England illegally. While Mary of Orange stood next in succession to James, her husband could not do much in opposition to that king; but he let it be known that his sympathies and those of his wife were with the constitutionalists. James had married for his second wife Mary Beatrix, a princess of the house of Este, and from this union had proceeded four children, all of whom had died. It seems to have been taken for granted that this couple were to have no more children, and that in due course James would be succeeded by his daughter Mary; but in 1687 the queen was declared to be pregnant, and on June 10, 1688, was born that prince who was afterward known as the pretender. This incident precipitated matters, for the opinion was almost universal in England that a supposititious child had been placed in the position of heir apparent to the crown. On June 30, 1688, William was invited to invade England at the head of an army. This invitation was signed by the earls of Shrewsbury, Devonshire, and Danby, by Lord Lumley, by Henry Sidney and Admiral Russell, and by Compton, bishop of London; and it was accepted. A variety of circumstances favored the undertaking, and on Nov. 5 William landed at Torbay, at the head of a well appointed army, 15,000 strong, composed of men of several nations. At first the people were slow to join him, and after advancing as far as Exeter he talked of returning to his ships; but men of note now began to repair to his standard, and it was found that James had no hold even on the great army which he had established in defiance of law. He was deserted by those upon whom he ought to have been able to rely, even his daughter Anne joining his enemies. He gave way to terror, hastened to undo all he had done, and fled. Brought back to London, he fled a second time, and reached France, whither he had sent his wife and son. All England was in the hands of William and his friends. The convention parliament that assembled conferred the crown on William and Mary, and in its declaration of right placed the vindication of the act on the ground of the "undoubted inheritance of Englishmen," the entire movement being conservative in its character, and not one of innovation. The events of 1688-9 are known as the English revolution, but it would be more correct to call them

the close of that revolution; for the contest that had commenced with the coming of the Stuarts to the throne, and which had lasted for 86 years, was virtually closed on the day that William and Mary were proclaimed king and queen of England. For almost two centuries the government of England has been constitutional without question, a circumstance totally without parallel in the history of great nations. If we except the rebellions of 1715 and 1745, that country has been the scene of no serious outbreak against established authority for six generations. Faults there have been in both government and people, but not greater than are to be found in the corresponding annals of other European nations; while in no other country of the old world has the good that England has known had an existence. Liberty and law have gone hand in hand together, each sustaining the other, mutually imparting a portion of their spirit. Moral, intellectual, and material progress through six generations has placed England foremost among nations, and left her in some important respects without a rival. The greatness of England, her moral power, and in no small degree her literature, and the fact that she is the mother of nations destined perhaps to excel herself, are all due to the happy settlement that was effected in 1688-9, which was the completion by one set of patriots of what other patriots had initiated or forwarded. William III. found his new throne anything but an agreeable seat, but it enabled him to combat Louis XIV. with ultimate success, though the war that England declared against France in 1689 was marked by many reverses. It was terminated by the peace of Ryswick in 1697. Ireland was subdued almost as completely as she had been by Cromwell. Several conspiracies were formed against the new government, but they all failed. Mary died in 1694, and left William sole monarch. The freedom of the English press dates from 1695. Most of the legislation of this reign was liberal, and would have been more so if William's wishes could in all cases have prevailed. Much of the evil of those times grew out of religious intolerance, and William was singularly free from bigotry, though few men have been more devout. The toleration act, which has been said to illustrate most strikingly the peculiar vices and the peculiar excellences of English legislation, was adopted in 1689. During William's reign the bank of England was established (1694), and the modern system of finance introduced. He entered into two partition treaties with Louis XIV. to dispose of the immense dominions of the Spanish branch of the house of Austria, Charles II. being without heirs of his body. Louis violated the second treaty in 1700, and William would have made war on him, but circumstances prevented; and there was every prospect that the entire Spanish monarchy would pass to Philip of Anjou without a serious struggle,

when Louis threw the whole British nation into a rage by acknowledging the son of the exiled James II. king of Great Britain, James dying in 1701. William was preparing for vigorous war when he died, March 8, 1702. The year before his death he had the satisfaction of seeing the finishing stroke put to the work of the revolution. In 1613 Elizabeth Stuart, daughter of James I., had wedded the elector palatine, Frederick V. The youngest child of this marriage was a daughter, Sophia, married to Ernest Augustus, first elector of Hanover. As early as 1689 William had been desirous of entailing the British crown on this lady, and the house of lords unanimously agreed to an amendment of the bill of rights to that effect. This bill declared that after the decease of both William and Mary, the crown should descend to the heirs of the body of Mary; or if she died without issue, to Anne of Denmark and the heirs of her body; or if she also was without issue, to the heirs of the body of William of Orange. The commons unanimously rejected the amendment. While the two houses were conferring on the subject, a son, afterward known as duke of Gloucester, was born to the princess Anne. Neither house would give way, and the bill of rights was lost. But the duke of Gloucester died in 1700, and in 1701 William's old plan was adopted, and the crown was entailed on the electress Sophia. All the descendants of James II. and Charles I. were passed over, and the preference given to a granddaughter of James I., for the sole reason that she was a Protestant. There were then living 57 persons who had claims to the crown superior to those of the electress, according to the received ideas of the right of succession. William was succeeded by the sister of his wife, Anne, second daughter of James II. In May, 1702, war was declared against France, that war which was illustrated by the deeds of Peterborough and Marlborough, and which lasted 11 years, when it was concluded by the treaty of Utrecht, in which the English are thought to have thrown away nearly all the fruits of their many victories. The war party had gone out of office in consequence of the hostility of the church, and their successors were supposed to aim at the restoration of the Stuarts. The union of England and Scotland was effected in 1707, the latter country being allowed to send 45 members to the house of commons, and 16 to the house of peers. Anne died Aug. 1, 1714, and the crown passed to the house of Hanover. The reign of George I. was by no means brilliant. The rebellion of 1715 in behalf of the Stuarts proved a failure, and the foreign movements for the same object were quite as useless. England allied herself with France, then ruled by the regent Orleans. The whigs returned to power, which they kept until the reign of George III. The South sea bubble caused great distress. Walpole's ascendancy began with its explosion, though he had been

in office long before that date. England was involved in war with Spain, and in 1718 won the naval victory of Cape Passaro. George I. died in 1727, and was succeeded by his only son George II., between whom and himself there had been bitter hatred. The new king, under the influence of his wife, Caroline of Anspach, continued Walpole in office, and that great minister was at the head of affairs until the beginning of 1742, baffling for years all the exertions of a most able and unscrupulous opposition. His principle of action was "to let well alone;" but he thought things were well which badly needed improvement. He allowed himself to be forced into a war with Spain, which departure from his system was soon followed by his fall, though he retained his influence over the royal mind to the day of his death. His successors were whigs in principle, and there was no chance for the Tories as a party under the first two monarchs of the Hanoverian line. War with France was added to that with Spain, growing out of the question of the Austrian succession. This war was one of the least glorious ever waged by England. In 1746 the contest between the reigning dynasty and the remains of the Stuart party was brought to an end at Culloden, where the duke of Cumberland defeated Charles Edward. The cruelties with which the Jacobites were punished reflect discredit on the English name. The treaty of Aix-la-Chapelle in 1748 restored peace to Europe for a few years. The whigs continued to rule, headed by Henry Pelham, and after his death in 1754 by his brother the duke of Newcastle. The renewal of the war with France in 1755 led to considerable ministerial changes, and in 1757 was formed the celebrated Pitt-Newcastle ministry, which carried on the contest with great vigor; so that when George II. died, Oct. 25, 1760, his fleets and armies were everywhere triumphant. The foundation of the East Indian empire of England was laid at Plassey, June 23, 1757. French America was conquered at Quebec, Sept. 13, 1759. The victories of Minden and Crefeld atoned for the days of Laffeldt and Fontenoy. Hawke's victory over Conflans was one of the noblest exploits of the British navy. The death of the king arrested the policy which had produced such results. The new king, George III. (the first English-born king of his house), grandson of George II., was by nature and education as despotic as the worst of the Stuarts, and resolved to attempt the restoration of the Stuart modes of government; and hence peace was his first object, that he might be at liberty for the work of internal change. He got rid of Pitt and made peace, but not until he had waged a brief war with Spain, that country joining the French in the last stage of the contest. The treaty was held to be very disgraceful to England, and it certainly was unwise to give up such islands as Martinique, Cuba, and the Philippines. Scarcely more wise was it

to retain Canada, whereby the English North American colonies were freed from any fear of French attacks, and any feelings of independence which they might have would be increased. Those colonies, however, would probably have been long in maturing the wish for separation from the parent country had they been well governed. With the exception of a few thoughtful men, the colonists were sincerely attached to the home government. The attempt of that government to tax them caused great indignation, and led to the American revolution. The English in the last years of the war had to fight the Americans, the French, the Spaniards, and the Dutch. The peace of 1783 left England in a low condition. She had been fortunate only in the East, where the ability and unscrupulousness of Warren Hastings increased her power. Shortly after the conclusion of the war George III. became popular, and saw the party which he hated excluded from office. The new phase of toryism which manifested itself under the rule of the younger Pitt became the ascendant political principle of England for more than 40 years. When the French revolution broke out, the English ministry reluctantly engaged in the war that soon followed. A portion of the aristocratic whigs, headed by Burke, were more anxious for war than were Pitt and his immediate followers. The war lasted, with two brief intervals, down to the summer of 1815, ending in the complete triumph of England and her allies. The exertions made by England were vast. Her fleets, led by Nelson, Jervis, Howe, and Duncan, achieved splendid victories over the French and Spaniards, and in the last years of the war her armies were greatly distinguished under the lead of Wellington and others. In 1810 George III. lost his reason finally, and for more than nine years his eldest son, afterward George IV., was prince regent, succeeding to the throne in 1820. In 1812 England became involved in a war with the United States, growing out of the impressment and right of search questions. The contest was terminated by the treaty of Ghent, Dec. 24, 1814. The colonial and Indian dominions were much extended during the contest with France. On the other hand, England found herself burdened with a debt of \$4,000,000,000, and her expenditures had been on the most gigantic scale. After the restoration of peace in 1815, England entered upon a career of reform which has been more or less steadily followed ever since. This reform at first related to commercial and legal matters, but soon reached to others more peculiarly political. The passage of the Catholic emancipation act in 1829, under direction of a ministry headed by Wellington and Peel, showed that religious bigotry was no longer to receive the direct countenance of government; and the proceeding was but the fulfilment of the spirit of the treaty by which Ireland had been united to Great Britain in 1801, and, her own

parliament being abolished, allowed to send members to the imperial parliament. George IV., who had begun life as a liberal in politics, opposed this act, but was compelled to yield to the pressure brought to bear upon him by the tory chiefs. He died the next year, 1830, and, having no legitimate children, was succeeded by his brother the duke of Clarence as William IV., whose short reign was a time of more political agitation than had been known since the revolution. Immediately after he became king happened the French revolution of July, 1830, which was followed by outbreaks in other parts of Europe, especially in Belgium and Poland. England felt these movements, and sympathized with the popular parties of the continent. In March, 1831, a bill for parliamentary reform was introduced into the house of commons by Lord John Russell, and after long debates in parliament and intense excitement in the country, caused by the opposition of the house of lords, a bill making extensive changes in the constitution of the house of commons finally passed in June, 1832, under the ministry of Earl Grey. The first reformed parliament, which met Jan. 29, 1833, contained an overwhelming majority of reformers. The dominant party, however, was too strong, and fell from its own weight. Irish troubles led to dissensions, and Lord Grey retired from office in 1834. He was succeeded by Lord Melbourne. Toward the close of the year Lord Althorp, chancellor of the exchequer, was obliged to vacate his office in consequence of his accession to the peerage as Earl Spencer. The king, who had been watching for an opportunity to get rid of the whigs, took this occasion to dismiss the ministry. The government was committed to Sir Robert Peel, who formed a conservative ministry, and made a bold effort to retain power, though it is not probable he would have advised the king to the step he had taken in dismissing the Melbourne ministry, for there were not 200 men in the commons who would have preferred the conservatives to the whigs. Parliament was dissolved, and in the elections which followed the conservatives gained largely; but the reformers had a majority, so that, though 35 reformers voted for the Peel candidate for speaker of the house of commons, he was beaten by a majority of 10. Peel continued in office until April 8, 1835, when he retired, having been repeatedly beaten on Irish church questions. His ministry had only lasted four months. Lord Melbourne returned to office, with many of his old colleagues. The king found himself forced to submit to the whigs; but it is said he was prepared to do something against them when he was seized with the illness which proved fatal to him, June 20, 1837. He was succeeded by his niece Victoria, the only child of Edward, duke of Kent, fourth son of George III. This event led to the separation of the crowns of England and Hanover, which had been worn by the same persons

since 1714, the Salic law prevailing in Hanover. The queen was very popular when she ascended the throne. She favored the whig ministry, which remained in office four years after her accession, though often rudely shaken, and once compelled to resign for a few days. There was a near approach to war with France in 1840, in consequence of disputes on the eastern question. In 1841 the long contest between the conservatives and the whigs came to a crisis, and after the latter had been more than once defeated, the house of commons declared its want of confidence in them by a vote of 312 to 311. Shortly afterward parliament was dissolved, and the subsequent elections ended in a conservative triumph. When parliament met, the ministers were beaten by 91 majority in the commons, and by 72 in the lords. They immediately resigned, and Peel formed a conservative ministry. The whigs, just before they had been expelled, had adopted the part of corn-law reformers, and the voice of the country was beginning to make itself heard on this question of food. In many respects Peel showed himself a reformer. He freed many articles from duties, and in other ways approximated to the position of a free trader. The more intense conservatives were dissatisfied, but the course of events was too much for them. The famine of 1845 compelled the ministry to discontinue their support of the protection policy, and the anti-corn-law league received much aid from the potato rot. The minister resigned, but was compelled to resume office, and to preside over the destruction of the corn laws, which were finally disposed of, June 26, 1846. The Peel ministry had from the first experienced much difficulty in the management of Irish affairs. The Melbourne ministry had pursued a liberal course toward Ireland, and received the support of Daniel O'Connell and his friends; but when the conservatives came into office, the Irish leader, between whom and the premier the utmost personal dislike existed, resumed the work of "agitation." He brought forward the repeal question, and meetings were held in various parts of Ireland, at which enormous numbers were present. Government interfered to prevent one of these meetings at Clontarf, Oct. 8, 1843. O'Connell, one of his sons, and eight other persons were arrested on charges of conspiracy, sedition, and unlawful assembling. They were tried and convicted, and O'Connell was sentenced to a heavy fine and a year's imprisonment, and required to find high recognizances to keep the peace for seven years. The case was carried before the house of lords, where the judgment of the lower court was reversed (Sept. 4, 1844). Though nominally beaten, government was really victorious, as from that time O'Connell's influence was essentially diminished. In 1846 the Peel ministry brought forward an act to protect life in Ireland, but it was defeated in the commons on the same day that the corn

laws were repealed, and the ministry came to an end, being succeeded by one at the head of which was Lord John Russell, and which ruled England through the European crisis of 1848-'9. A weak attempt to get up an insurrection in Ireland was put down, and the chiefs in it were transported. The Russell ministry went out of office in 1852, and for several months the tories, led by Lord Derby and Mr. Disraeli, were at the head of affairs. This ministry was followed by one composed of coalesced whigs and Peelites, headed by Lord Aberdeen. In 1853 the troubles on the Turkish question began, and war was declared against Russia by France and England in March, 1854. Large fleets and armies were sent to the East, and fleets to the Baltic. The Crimea was invaded, the victory of the Alma won by the allies, and Sebastopol partially invested. The Russians brought up large forces, lost the battles of Balaklava and Inkerman, but were more successful in defending Sebastopol. Winter set in, and great sufferings were experienced by the besiegers. Alarming accounts of the sanitary condition of the army reached London, and although the allies had destroyed Bomarsund in the Aland islands, their expedition to the Baltic had failed. Much irritation existed in England, under the effect of which the Aberdeen ministry broke down, and was succeeded by one at the head of which was Lord Palmerston. The war was continued in the Crimea during the winter, but little progress was made in the siege. In the spring some brilliant successes were achieved; but on June 18 both French and English were repulsed in attempting to storm the Malakhoff and the Redan. Lord Raglan, the English commander, died soon after, and was succeeded by Gen. Simpson. On Sept. 8 the French stormed the Malakhoff, while the English failed before the Redan. The Russians immediately abandoned Sebastopol, and the war was now virtually at an end. Peace was restored by a congress of the great powers at Paris, in March, 1856; but England signed it reluctantly. It was as well for her that peace was restored, for not much more than a year after, and while engaged in hostilities with Persia and China, a conspiracy was formed in her great Bengal army of sepoys, which broke out in January, 1857. Delhi fell into the hands of the sepoys, and the nominal Mogul emperor found himself once more a sovereign in reality. The mutiny spread rapidly, and in a short time the whole Bengal army had become hostile to the English. The contest that followed led to the complete reestablishment of the English ascendancy. The military reputation of England was greatly raised by the successes of her armies in India, achieved under the lead of Sir Henry Havelock, Sir Colin Campbell, and others. In eight months after the breaking out of the mutiny there were nearly 70,000 effective English troops there, and new native corps had replaced the sepoys. By the end of 1858 this formidable revolt was totally

suppressed, and the few mutineers that remained were reduced to the condition of wandering brigands. The rebellion resulted in the transfer of the immediate government of India from the East India company to the crown, the old directory sitting for the last time Sept. 1, 1858. But the ministry under which measures so thorough had been initiated became unpopular, because it was supposed to be too subservient to the policy of France. A hostile vote in the house of commons in February, 1858, drove the Palmerston ministry from office, and a new conservative ministry was formed, with the earl of Derby as premier, and Mr. Disraeli as chancellor of the exchequer. This ministry soon resigned, and Lord Palmerston resumed office in June, 1859. England made some ineffectual efforts to prevent the war in that year between Austria and Italy. In 1860 an important commercial treaty was made with France, chiefly through the agency of Mr. Cobden, the leader of the English free traders. In 1861 great efforts were made to stimulate the cultivation of cotton in India, in view of the cutting off of the ordinary supply by the civil war in America. On May 13 the queen recognized the belligerency of the insurgents in America and the blockade of their ports, and proclaimed neutrality between the contending parties. In November Com. Wilkes, of the United States frigate *San Jacinto*, seized the confederate commissioners to England and France, from the British mail steamer *Trent*, then in the *Bahama* channel. This event created great excitement in England, but the commissioners were surrendered by the United States government. On Dec. 14 the prince consort Albert died. In the manufacturing counties there was great suffering from the cotton famine. In October, 1862, more than 150,000 operatives in Lancashire were entirely out of work, and 120,000 others were working only half time. This distress led some to urge the government to break the blockade of the cotton states; but it refused, and also declined the proposal of the emperor of the French for a joint mediation in American affairs. Government help was given to the distressed operatives, and private donations were made amounting to more than £1,000,000. Diplomatic correspondence with the United States in regard to the depredations of the privateer *Alabama* led to more settled feelings as to the American conflict, and on May 13, 1864, Mr. Cobden offered in parliament a petition for more practical efficiency in preventing violations of neutrality. On March 10, 1863, the prince of Wales was married to the princess Alexandra of Denmark. The throne of Greece was declined by Prince Alfred, and in 1864 the Ionian islands were finally ceded to Greece. In February of this year Denmark asked help of England against Prussia and Austria, and a conference in regard to Schleswig-Holstein met in London April 25; but nothing was done. The parliament elected in 1865 was strongly liberal. On

Oct. 18 Lord Palmerston died, having been premier, except for a very short period, since 1855, and Earl Russell took his place; but a reform bill introduced by the ministry being rejected by parliament as insufficient, they resigned. The conservative ministry which now came into office, headed successively by the earl of Derby and Mr. Disraeli, proposed a measure of reform more liberal than that of the liberals; and a bill was passed which effected the greatest change in the constituency of the house of commons since the reform bill of 1832. The act of 1867-'8, giving the suffrage to all householders, with certain limitations, increased the number of electors in England and Wales from 1,056,659 in 1866 to 2,012,631 in 1868. In 1868 an army organized at Bombay, under the command of Sir Robert Napier, and comprising 4,000 British and 8,000 sepoy troops, invaded and conquered Abyssinia, whose king Theodore had imprisoned and otherwise ill-treated a number of British subjects. Magdala, the chief fortress of the country, was captured by storm on April 13, when Theodore committed suicide. The British captives being released and the king dead, the English retired from the country without delay. In 1868 Mr. Gladstone introduced a bill for the disestablishment of the Irish church, and after a sharp struggle carried it through the house of commons against the government. Parliament was dissolved Nov. 11, and a most exciting election resulted in a liberal majority of 112. The ministry resigned before the meeting of parliament, and Mr. Gladstone was called to form a new ministry, of which John Bright became a member. The Irish church disestablishment finally became a law in July, 1869. The diplomatic correspondence with the United States in regard to the depredations of the privateer *Alabama* was continued, and a treaty was negotiated by Reverdy Johnson, minister to England, but rejected by the United States senate. The endowed schools for elementary instruction formed the subject of a report to parliament in 1869, which showed that the income of these schools, amounting to £592,000, was mostly wasted. A bill was then passed to give these schools real efficiency. In 1870 a general education act was passed, which aims to use all the old schools efficiently, organizes England and Wales into school districts, and provides for destitute regions by local taxation and by parliamentary grants. Education is not made free, but the school board of each district has power to remit school rates and to enforce attention to education. Under this act 300 school boards were at work in 1871, and included some of the most eminent and liberal men of the nation. Religious tests in the universities were abolished, as to all lay students, June 16, 1871. A bill for the abolition of the purchase and sale of commissions in the army was carried through the house of commons, but rejected by the lords, when the ministry took the unusual course of abolishing

the purchase system by royal warrant issued July 20, 1871. A commission was appointed the same year to settle the Alabama claims and the questions growing out of the fisheries on the coast of the eastern provinces of British North America. The commission met in Washington, where a treaty was signed May 8, which was quickly ratified by both governments. This treaty referred the Alabama claims to a board of arbitration to meet in Geneva, the northwestern boundary question to the emperor of Germany, and the other questions to a joint commission of three. The Geneva arbitration, after throwing out the claims of the United States for indirect damages, awarded an indemnification of \$15,500,000, which was finally paid at Washington in September, 1873. The emperor of Germany decided the boundary question according to the claim of the United States. In the great war between France and Germany in 1870-'71 England took no part. —*English Constitution.* The English constitution is not any formal instrument, adopted by a convention, but is the growth of all English history. Its commencement must be looked for in the time of the Roman occupation, which not only was a grand civilizing agency, but had its effect on those Germanic conquerors whom we call Anglo-Saxons. The Saxons, while destroying the male Britons, probably spared and married their women. This gave to England an important Celtic element. The invaders probably occupied the Roman towns. The conversion of the Anglo-Saxons to Christianity was an important step toward their civilization, and developed their characteristic ideas of order and law. They were gradually forming a Christian state, when the arrival of the Danes brought in a new element, favorable to the production of a free state. Both the aristocratic and the democratic element entered into the Saxon polity, the former attaining a decided predominance. The free classes were divided into *thanes* and *ceorls*, the former being nobles and gentry, and the latter the mass of the people. The possession of property determined the position and rights of the freemen. The thralls or slaves do not appear to have been very numerous. The local organizations regulated for the most part their own affairs. The country was divided into counties, the counties into hundreds, the hundreds into tithings. The county courts, and those of the hundreds, were popular tribunals. The witenagemote was the highest assembly, and was thoroughly aristocratic. The king presided in it, and it met by his summons. The earls, nobles by birth, as the *thanes* were from possession of property, attended it, and so did bishops and abbots. The *thanes*, too, had the right to sit in it. The local magistrates are supposed to have been occasionally present. The common people had no part in it, and were not represented. It made laws, and voted taxes when they were needed. It controlled the king, and could elect

him from among the members of the royal line. It was the highest court in all cases. The clerical influence in it was great, as it was throughout the country. The witenagemote had some of the elements of parliament, and its existence was not without effect in helping to form the polity that now exists. The Saxon aristocracy increased their power as time went on. The higher earls were fast becoming rulers of the state, when they and the people, Saxon and Danish, were all subdued by the Normans, another northern race, which had materially changed its character by a long residence in France. The conquest effected great changes in England. William I. introduced the feudal system into England, but with such modifications as prevented the sovereign from being enslaved by the nobility. The theory that the king of England is the supreme lord of all the land was established by the conqueror. This supremacy was directly and solemnly admitted by all the landed men of England in 1086, in an assembly at Salisbury. The lands which the king conferred on his followers were scattered over the country, so that it was impossible for his tenants *in capite* to increase into territorial potentates, as in France and elsewhere on the continent. He kept up the Saxon courts, but withdrew from the county courts cognizance of ecclesiastical matters. These popular courts he made more popular. This judicial system tended to keep down the baronial courts, which, like the barons themselves, never attained such consequence in England as they did elsewhere. Half the people were slaves, living in villeinage. Those attached to the soil, like the late Russian serfs, were villeins *regardant*, while the others, who could be sold away from the land, were villeins *en gros*. The number of the latter was not large. This was the result of the Norman rule, the English peasants being reduced to the condition of those of Normandy. In the reign of Henry II. the work of redemption began. Judicial interpretation was favorable to the enslaved classes. At the beginning of the 13th century there was a class of free laborers in England, small in numbers, but embracing the humbler people of the towns, and some of the peasants. The free peasant, no matter how complete his poverty, was compelled to be enrolled in the *decenna*, or subdivision of the hundred to which he belonged, and performed certain local political duties. He could act on inquests or juries. The landowners were tenants in chivalry, or holders by military tenure, and included the barons and other great men holding immediately of the crown, whose burdens were as great as their honors; tenants in free socage, who have been compared with the modern yeomanry, and whose condition was as good as that of any class of men in that time; and tenants in villeinage, men who had been emancipated, and who continued to reside on their old places, rendering their old services, or freemen who had taken

their places on the condition of discharging their obligations. There were not many of this last class of holders at the commencement of the 13th century. The conquered towns had passed into the hands of the Normans, but had obtained a certain degree of freedom by purchase, and also by charters, yet were liable to be specially taxed for the benefit of their lords. Such was the condition of England when John became king and carried the ordinary Norman tyranny to an extent that never was thought of by any of the preceding kings. A council of barons and prelates was held in 1213, at which Langton, archbishop of Canterbury, brought forward a charter of Henry I., which was well received. Another council was held in 1214-15, which extorted Magna Charta from the king. The charter itself is dated June 15, 1215, but the conference was not concluded until the 19th. The great charter, one of the landmarks of the history of freedom, laid the foundation of the English constitution in its broad and definite sense. It was renewed, with some omissions, in the reign of Henry III., who also granted the charter of the forest, modifying the forest laws. These charters were renewed five times in the same reign. The charter of Henry III. has been 30 times confirmed. The most remarkable of these confirmations was in the 25th year of Edward I. The government, as established in the 13th century, provided for a hereditary monarch with limited powers, taxation by parliament, punishment to be inflicted only after lawful trial, the cessation of arbitrary fines and imprisonment, trial by jury, and justice without price or delay. Parliament attained the distinctive character which it has had for more than 600 years in 1265, when borough representation was created. Knights of the shire were earlier summoned to the great council, and it was the intention of those who framed Magna Charta that cities and boroughs should be represented; but 50 years elapsed before their plan was carried out. Councils without burgesses continued to meet for some time after the establishment of parliament. That England obtained a symmetrical constitution in the 13th century, or that she has ever had anything of the kind, is not pretended by the most partial vindicators of her polity; but it is claimed, with strict justice, that then she became distinctly a free state, and that since that time she has been able to maintain liberty and order to an extent, and for a length of time, unknown to any other country. Monarchs and ministers frequently disregarded the restraints placed on them by the laws, but not even the most arbitrary of kings or the most reckless of ministers has ever gone beyond a certain line, save to be destroyed. The constitution continued to develop itself, and early in the 14th century we find the house of commons a great admitted power in the state. In the reign of Edward III. this body complained of the conduct of the

king's ministers, and in 1376 the first impeachment by the commons took place. In the affairs of war and peace the commons were then often consulted. It was provided that there should be frequent sessions of parliament, and 48 were held in the reign of Edward III. The minority of Richard II., and his weakness when he became of age, favored the growth of the power of the commons. That king sought to "pack" the house in 1398, a plain proof of its consequence. Parliament aided to depose Richard II., and to confer the crown on Henry IV., over the superior claim of the line of Clarence. Hallam, speaking of things as they were at the close of the 14th century, says: "Of the three capital points in contest while Edward III. reigned—1, that money could not be levied; 2, or laws enacted without the commons' consent; and 3, that the administration of government was subject to their inspection and control—the first was absolutely decided in their favor, the second was at least perfectly admitted in principle, and the last was confirmed by frequent exercise." In the 9th year of Henry IV. it was recognized that all money bills must originate in the lower house, and that the king should not take cognizance of the subject of that body's deliberations until it had decided upon it, and brought its decision before him regularly. Freedom of speech was reluctantly allowed by the sovereign, and Henry IV. did what he could to prevent it; and in the reign of Henry VI. a member of the commons was imprisoned because of a motion he had made; but as that motion related to the succession to the throne, and was made not long before the outbreak of the wars of the roses, perhaps the severity exercised toward him was owing to the jealousy which the Lancastrians felt toward the Yorkists. Members were then first privileged from arrest. Laws were passed to lessen the influence of the crown in elections, and to determine the qualifications of voters and representatives. At this time the desire to enter parliament was commonly felt, whereas in the preceding century it had been found necessary to enforce the election of representatives, while electors complained of the burden of paying members. The wars between the houses of York and Lancaster raised the consequence of the house of commons, as each party had to appeal to that body, and employ the power of parliament against its enemies. In 23 Henry VI. it was sought to provide that knights of the shire should be of gentle birth, but the law could not be enforced. There was a strong hereditary aristocracy; "but," says Macaulay, "it was of all hereditary aristocracies the least insolent and exclusive. It had none of the invidious character of a caste. It was constantly receiving members from the people, and constantly sending down members to mingle with the people. Any gentleman might become a peer. The younger son of a peer was but a gentleman.

Grandsons of peers yielded precedence to newly made knights. The dignity of knighthood was not beyond the reach of any man who could by diligence and thrift realize a good estate; or who could attract notice by his valor in a battle or a siege. It was regarded as no disparagement for the daughter of a duke, nay, of a royal duke, to espouse a distinguished commoner. Thus Sir John [Sir Robert] Howard married the daughter of Thomas Mowbray, duke of Norfolk. Sir Richard Pole married the countess of Salisbury, daughter of George, duke of Clarence. Good blood was indeed held in high respect, but between good blood and the privileges of peerage there was, most fortunately for our country, no necessary connection. Pedigrees as long, and escutcheons as old, were to be found out of the house of lords as in it. There were new men who bore the highest titles. There were untitled men well known to be descended from knights who had broken the Saxon ranks at Hastings, and scaled the walls of Jerusalem. . . . The yeoman was not inclined to murmur at dignities to which his own children might rise. The grandee was not inclined to insult a class into which his own children must descend." It would be wrong to infer from the real power and great consideration of parliament, that the king was not a sovereign of the first rank. He was very powerful, and did many things difficult to reconcile with the idea of the chief of a constitutionally governed country. Much depended on personal character, but even the weakest of kings possessed great prerogatives, and found not much difficulty in occasionally evading or violating the law, without causing public commotion. With three or four exceptions, all the English sovereigns that reigned between the days of Hastings and Bosworth were men of distinguished talents and much energy; facts that explain why liberal principles made no greater progress, and also show the earnestness of the English for free institutions, which were gained by no ordinary means from monarchs of such abilities, who were naturally averse to everything that tended to lessen their authority. The Tudors made great changes in various respects. Yet, says Froude, "in the house of commons, then as much as now, there was in theory unrestricted liberty of discussion, and free right for any member to originate whatever motion he pleased. But so long as confidence existed between the crown and the people, these rights were in great measure surrendered. The ministers prepared the business which was to be transacted; and the temper of the houses was usually so well understood that, except when there was a demand for money, it was rare that a measure was proposed the acceptance of which was doubtful, or the nature of which would provoke debate. So little jealousy, indeed, was in quiet times entertained of the power of the crown, and so little was a residence in Lon-

don to the taste of the burgesses and the country gentlemen, that not only were their expenses defrayed by a considerable salary, but it was found necessary to forbid them absents themselves from their duties by a positive enactment." Throughout the entire existence of the Tudor dynasty there were instances of the sovereigns retreating from positions they had assumed, when they found they had done what was unpopular; and they retreated so well as always to save their dignity, and to prevent their prerogatives from being called in question. The resistance which the Tudors experienced when they endeavored to tax their subjects too highly can leave no doubt that the power of the people was as great as ever it had been, and that the new dynasty, whatever else it succeeded in changing, did not effect any change in the English character. They certainly bore hard upon the aristocracy, but this rather helped them with the people. The peerage was not then extensive. The first parliament of Henry VII. contained but 29 temporal peers, while in the parliament of 1451 there had been 53. The aristocracy had suffered immensely in the wars of the roses. The Tudors not only struck down many of its noblest members, but also elevated men from among the gentry and lawyers. The names of Russell and Seymour were not noble until the time of Henry VIII., or later. The Dudleys then rose to note. But whether new or old, the aristocracy were the true serviles of the Tudor times, not the people. Henry VIII., the most arbitrary of all the Tudors, says Bolingbroke, "by applying to his parliaments for the extraordinary powers which he exercised, and by taking these powers for such terms and under such restrictions as the parliament imposed, owned indeed sufficiently that they did not belong of right to the crown. He owned likewise in effect, more than any prince who went before him, how absolutely the disposition of the crown of England belongs to the people of England, by procuring so many different and opposite settlements of it to be made in parliament." The increased weight of the commons in the Tudor reigns is proved by the desire of the government to obtain victories at elections. New boroughs were then created for the express purpose of adding to the government's influence in the house of commons, and to this action are attributed the irregularities that have existed in the popular representation of England. Government interfered in elections, and bribed members of the house. Henry's daughter, Mary, dissolved two parliaments because they would not do what she desired; and the third was not always compliant. The abbey lands could not be restored to the church, nor the English crown settled on Philip II., because of the hostility of parliament to both schemes. The reformation had great political effects, the chief of which was the increase of the power of the crown. Henry VIII. was pope of Eng-

land for a time as well as king. His ecclesiastical supremacy was exactly what the words mean; but this was owing to circumstances and to his personal character, and his system died with him. When the Anglican church was finally established under Elizabeth, the sacerdotal character of the sovereign was disclaimed; but she held a vast power over the church, the ecclesiastical jurisdiction of the crown being complete. "The act of supremacy," says Hallam, "empowered the queen to execute it by commissioners appointed under the great seal, in such manner and for such time as she should direct; whose power should extend to visit, correct, and amend all heresies, schisms, abuses, and offences whatever, which fall under the cognizance and are subject to the correction of spiritual authority." After several temporary commissions had sat under this act, the high commission court came into existence in 1583. A more arbitrary tribunal never existed. Burleigh opposed the procedure under it, but, influential as he was, his opposition availed nothing. The house of commons was hostile to the high ecclesiastical party, and its opposition was not that of a servile body. "The regiment of England," said Aymer, afterward bishop of London, "is not a mere monarchy, as some for lack of consideration think, nor a mere oligarchy, nor democracy, but a rule mixed of all these, wherein each one of these has or should have like authority. The image whereof, and not the image but the thing indeed, is to be seen in the parliament house, wherein you shall find these three estates: the king or queen which representeth the monarchy, the noblemen which be the aristocracy, and the burgesses or knights, the democracy. If the parliament use their privileges, the king can ordain nothing without them; if he do, it is his fault in usurping it, and their fault in permitting it. Wherefore, in my judgment, those that in King Henry VIII.'s days would not grant him that his proclamation should have the force of a statute were good fathers of the country, and worthy commendation in defending their liberty." This was written in 1559, the first year of Elizabeth and the 74th of the Tudor rule; and it is not possible that it could have been written had England been despotically governed by the Tudors. To the same purport are the observations of a far greater writer of the Elizabethan time, made in its last days. "I cannot choose," says Hooker, "but commend highly their wisdom, by whom the foundation of the commonwealth hath been laid; wherein, though no manner of person or cause be unsubject unto the king's power, yet so is the power of the king over all and in all limited, that unto all his proceedings the law itself is a rule." The contest that commenced when the house of Stuart succeeded to that of Tudor, the opening scene of the English revolution, was the work of the government, and the revolutionary party consisted of that govern-

ment and its adherents. The "country party," as the opposition came to be called, was in the strictest sense of the word a conservative party; and if, in the course of the long struggle of 86 years, it had occasional resort to acts apparently revolutionary, it was because the security of liberty was found compatible only with the removal of that government which would have overthrown the last survivor of those constitutions of which there had formerly been so many in Europe. The divine right theory, which was so zealously preached in the reign of James I., was meant to prepare the way for the subjugation of the people, and for the concentration of all power in the hands of the central authority. Charles I. was bent upon not being a Venetian doge, and some able modern writers have written as if they believed there was a close resemblance between a king of England, who had only to rule according to law and his oath, and the shadowy phantom that did not even play at ruling on the Adriatic. A great power has always been wielded even by the most constitutionally inclined English monarchs, and popular feeling has often been with such kings against the aristocracy, but always on the condition that the king ruled according to law, a fact that it was impossible for Charles I. to comprehend. The contest was for power over the purse; which secured, power over the sword followed as of course. The third parliament of Charles I. passed the petition of right, an instrument superior to Magna Charta itself, and to which the king gave his consent. In it are pointed out the breaches that had been made in the law, the constitutional rights of Englishmen are declared, and the king is prayed to rule legally. Even if there had been a despotism in England previous to 1628, it ought then to have come to an end, after king and parliament had solemnly agreed upon the terms on which the government should thereafter be carried on. Yet the king violated the petition of right in the most flagrant manner, and did not call a parliament for 11 years, which was unprecedented. During that time England was as arbitrarily governed as France by Richelieu, without any of that glory which Richelieu's foreign policy was gaining for France. The machinery of despotism was found to be perfect within certain and by no means narrow limits. The jurisdiction of the court of star chamber was very great, and the proceedings in that court were more numerous and violent than they had been under the Tudors. The objects aimed at appear to have been to accustom the people to the administration of justice by a court directly dependent upon the king, and uncontrolled by law or precedent, and to increase the royal revenue by penalties and forfeitures. The cruel, atrocious punishments inflicted by the star chamber are as well known as the sentences passed at the bloody assizes. The council of the north, which had been created by Henry VIII., but which for 96 years had compara-

tively limited powers and jurisdiction, was converted into a star chamber for all that part of England which lies between the Humber and the Tweed. Wentworth, the president of this council, contrived to make it even worse than it would have been under the presidency of any other man. Proclamations were frequently resorted to, and were made to have the force of law. They intermeddled with almost every department of life, to the great grievance of the subject. Yet nothing can be clearer than their unconstitutionality; and until the Stuart age they were but little known. James I. made them common, and his evil example was outdone by his successor. The case of ship money has attracted extraordinary attention, which is in part due to the character of Hampden; but it was one then calculated to excite all men's attention in itself, for it showed that no dependence could be placed on the common-law courts, and that those tribunals were nearly as bad as the irregular tribunals which Charles, and Wentworth, and Laud employed to plunder the property, to restrict the liberty, and to mutilate the persons of Englishmen. "Ship money," says Hallam, "was held lawful by Finch and several other judges, not on the authority of precedents, which must in their nature have some bounds, but on principles subversive of any property or privilege in the subject. These paramount rights of monarchy, to which they appealed to-day in justification of ship money, might to-morrow serve to supersede other laws, and maintain new exertions of despotic power. It was manifest by the whole strain of the court lawyers, that no limitations on the king's authority could exist but by the king's sufferance. This alarming tenet, long bruited among the churchmen and courtiers, now resounded in the halls of justice." A reconciliation was sought with Rome, and Catholic troops were to be employed to control the Scotch and English. Even had there been no religious grievances to complain of, the political grievances were so vast and so various, that they would have justified a resort to arms on the part of all who cared for constitutional government. But there were religious grievances in abundance, though so "thorough" had been the repression exerted by Laud, that he could report to his master a most happy absence of nonconformity in 1639, "on the very eve of a revolution, in which primate and church, and monarch and monarchy, were to perish together." The religious element had much to do with bringing about the contest that commenced in 1640. The fourth parliament of Charles I. met in April, and was soon dissolved; and six months later met the most memorable parliament that ever assembled. That parliament fought the battle of the constitution, and fought it successfully. The entire machinery of despotism was broken down, most of it never to be rebuilt. The star chamber, the council of the north, and the high commission

court disappeared from England, the first two for ever, and the last to be only temporarily revived by James II. This would have ended the quarrel could the king have been trusted. But to trust him was quite out of the question, and parliament, to preserve the freedom of the country, resorted to measures which were not according to the letter of the constitution, though in keeping with its spirit. The king was forced to agree that parliament should not be dissolved without its own consent, which was an invasion of his prerogative; and later it was resolved that no minister should be appointed or peer created without the consent of parliament, and that the king should be made to resign the supreme military authority, which he justly held to be the very flower of the crown, and which was unquestionably one of its most ancient attributes. This conduct, indefensible on mere technical grounds, was proper in reference to the object in view, which was to put an end to illegal government by the king, who had repeatedly proved himself incapable of keeping his word. War soon broke out, and the king was supported by a large number of constitutionalists, men who were prepared to maintain the government as it was after the early reforms of the long parliament had been accomplished, but who dreaded innovation. The war led to the suspension of the constitution, and the protectorate of Cromwell was mainly a government by the sword, in spite of the fact that the protector sincerely wished to rule as a constitutional monarch. In 1660 the house of Stuart was restored, without anything having been done to secure legal rule. The old polity came once more into full force. The government was what it had been, nominally, before Charles I. and parliament appealed to the sword, though the star chamber and high commission courts, and other institutions of tyranny, no longer had place in England. Tenures by knight service were abolished, and most of the soil of England was held under that tenure. The parliament of 1661, which lasted down to 1679, was fanatically attached to royalist principles, and to its fanaticism must the bad government of Charles II. in no small degree be attributed. His reign is one of the worst in English history, but his first parliament was as bad as the king. Yet in that reign much was done that had permanent effect on the constitution. The dispensing power was condemned by parliament, and its illegality admitted by the king himself. The test act was passed. The *habeas corpus* act, which supplied a proper system of procedure to preserve the liberty of the subject, was adopted, and received the support of all Englishmen who were not anxious to see despotism established. Parliament made war or peace at its pleasure. It was now obvious not only that parliament had become the chief power in the state, but that the house of commons was virtually parliament. To counteract this, the king adopted

a plan recommended by Sir William Temple. He created a new council, or extended the privy council to 30 members, 15 of whom were to be the chief ministers, while the others were to be nobles or gentlemen, without office, but of wealth and consideration. It was expected that this council would satisfy all parties, but it satisfied nobody, and failed from the commencement of its existence. The old form was soon restored. A tory reaction made the calling of parliament together unnecessary in the last years of Charles II. His successor, James II., not content with an amount of power such as no other sovereign of his line had possessed, entered upon a course of action that plainly showed he had in view the total overthrow of the constitution both in church and state; and as his staunchest supporters had been churchmen, all parties in England were soon arrayed against him, except a few Catholics and a small portion of the dissenters. He had called a parliament immediately after his accession, and though it was the most servile body that had met for 80 years, and the king had said there were only 40 members of the house of commons whom he would not have named himself, he soon quarrelled with it. The ends which he had most at heart were, the repeal of the *habeas corpus* act, the establishment of a standing army, and the repeal of all laws that were directed against the Catholics. It so happened that these three things were precisely those which his own friends, the tories, were least inclined to grant. They were as much attached to the *habeas corpus* act as were the whigs; they associated the idea of a standing army with the military rule of Cromwell; and they saw ruin to the church of England in relief to the Catholics, and the one thing which they loved better than either monarch or monarchy was that church. For three years James carried on a warfare against the constitution, reviving the high commission court by his own act, and in defiance of acts of parliament, and in various other ways showing his utter contempt of all restraint. The events of 1688-9 removed him from the throne, and placed the constitution on a firm basis, on which it has since rested without serious disturbance. The government of parliament was then fairly acknowledged, and has never since been called in question. In the reign of William and Mary, and of William III., many things were done to settle the principles of the constitution. The declaration of rights adopted by the convention parliament was confirmed by the regular parliament, soon after; and the act of settlement passed in 1700 contains eight additional articles, further limiting the power of the crown, and protecting popular freedom. The most important of these articles is the seventh, by which judges were to hold their seats during good behavior, and their salaries were to be ascertained and established. The first mutiny bill was passed in 1689, and has since been renewed annually ever

since, giving to parliament control of the sword. A triennial bill was passed in 1694, but septennial parliaments were established in 1717. As the law originally stood, the king could keep the parliament chosen immediately after his accession to the throne during the whole of his reign. The triennial act repealed this prerogative, and the septennial act confirmed that repeal, while it extended the time for which parliament might endure. No parliament, however, since that time has existed for seven years. The laws relating to treason, to libel, and to toleration, passed in the year immediately following the revolution, and which became part of the constitution, were generally of a liberal character. After the accession of the house of Hanover, an attempt was made by a portion of the whigs to close the house of peers. George I. gave his consent to the introduction of a bill by which, after a few more creations, no additions were to be made to the peerage. For the 16 elective peers of Scotland, 25 hereditary peers were to be substituted. This measure succeeded in the house of peers, but the house of commons, under the lead of Walpole, threw it out. The government was strictly parliamentary down to the beginning of the reign of George III. That monarch attempted to rule parliament, and did not desist until he found that his best chance to accomplish his purpose would be through a union with that body. The demand for parliamentary reform commenced in the time of the American revolution, and was caused by the conviction that began to prevail among men of all classes that the existing abuses were owing to the vices of the electoral system. The French revolution had the effect of delaying changes in England that were much demanded, as numerous members of the house of commons were returned by peers, or by rich individual commoners. The reform bill of 1832, and that of 1867-8, though greatly enlarging the constituency of the house of commons in some respects, did not lessen the power of that body, which is more influential now than ever before. The exclamation of Mr. Roebuck in 1858, "The crown! it is the house of commons!" expresses the precise character of the government of the British empire. (See PARLIAMENT.) The sovereign, in theory, is almost as powerful as in early times, but in practice his power can hardly be said to exist. He can make war or peace, but the control of the purse and the sword by parliament neutralizes that prerogative. The money to pay the salaries of the officers he appoints must be voted by parliament. He cannot alter the standard of the money which it is his privilege to coin. The appointments he makes are virtually made by parliament, the ministers being only a committee of members of that body, selected from it by its consent, and responsible to it. He is held to be incapable of doing wrong, and the ministers are responsible for all that is done in his name, which, whatever its

justice in former times, is proper now, the king being capable of doing nothing, while his "advisers" do everything. He is head of the church, but he cannot alter the state religion, and should he become a Roman Catholic he would forfeit his crown. The succession to the crown is what is known as semi-Salic; that is, females can inherit and transmit the sovereignty. Females of a nearer consanguinity to the sovereign take precedence over males of a more remote degree; but in the same degree of consanguinity males, irrespective of order of birth, take precedence over females. The privy council is appointed by the king, and is bound to advise him to the best judgment of the members. With the advice of this body the king can publish proclamations, provided they are of a legal character. The council can inquire into all offences against government, and commit offenders for trial. The judicial committee of the council is a court of appeal in cases of lunacy and idiocy, and in admiralty and plantation causes, in questions between colonies, and all kindred questions. It has an appellate jurisdiction over all parts of the empire, except Great Britain and Ireland, in the last resort. The executive government is in the hands of the ministry, which consists of the leading men of the dominant party. This has not always been the custom, for though there have always been ministers, a ministry was not formed till after the revolution, of which event it was one of the consequences. The cabinet, though now formed from the ministry, and often confounded with it, is not identical with it, and is indeed much older than the ministry. It originated in the custom, which was inevitable, of intrusting power to some few of the king's ministers. In the reign of Charles I. this knot of ministers, or "junto," as they were called, were in the habit of holding meetings in the cabinet of the queen consort, Henrietta Maria, whence the name came to have its present meaning. The word *cabal* had the same meaning for a time, but the unpopularity of the cabal ministry, in the reign of Charles II., caused it to become so odious that it has never since been employed in a respectful sense. The cabinet, or rather the cabinet council, has never been recognized by the law, it has no legal existence now, the names of the persons who compose it are never officially published, and no record of its doings is kept. The difference between the cabinet and the ministry may, perhaps, be best stated by mentioning the composition of the existing English government. The ministry now consists of 31 persons, but the cabinet has only 16 members, viz.: the first lord of the treasury, chancellor of the exchequer, lord chancellor, president of the council, lord privy seal, secretaries of state for the home department, for foreign affairs, for the colonies, for war, and for India, first lord of the admiralty, first commissioner of works, chief secretary for Ireland, president of the local government board, vice president of the edu-

cation committee of the privy council, and the chancellor of the duchy of Lancaster. Among the ministers who are not of the cabinet are the commander of the forces and the postmaster general. The post of prime minister, or premier, has generally been held by the first lord of the treasury since the accession of the house of Hanover. It was most commonly held by the lord treasurer in earlier times, but there has been no such officer since 1714, the office being in commission, and it was Sir Robert Walpole who first attached the place of prime minister to that of first lord commissioner of the treasury. Previous to that time a secretary of state had higher official rank than the head of the treasury; and after Walpole's fall, Lord Carteret (Earl Granville) was the principal man of the ministry to which he belonged, and was a secretary of state. It has sometimes happened that force of character has enabled a secretary of state to be premier in fact if not in name, as in the cases of the elder Pitt, Lord Castlereagh, and Mr. Canning; but the rule is, that the first lord of the treasury is premier. The two offices of first lord of the treasury and chancellor of the exchequer have sometimes been held by the same person, as they were for a time by Mr. Gladstone in 1873. The king can call a privy councillor to the cabinet, though he hold no office; and eminent men have sat in that body merely as cabinet councillors.—The principal authorities for the general history of England are: the works of Turner, Palgrave, Kemble, and Lappenberg, on the Saxon times; Hallam's "Europe during the Middle Ages," and "Constitutional History of England;" Thierry's *Conquête de l'Angleterre par les Normands*; Freeman's "History of the Norman Conquest;" the works of Stephen, Creasy, May, and Raikes on the English constitution; the histories of England by Hume, Lingard, Knight, Mackintosh, Macaulay, and Froude, the last three being devoted to special portions of that history; and Pauli's continuation of Lappenberg.

ENGLAND, Church of, the church established by law within the realm of England, and until 1871 of Ireland. Its origin is readily traced in English history, Christianity having gained a foothold in England at a very early date, and assumed from the first a more or less perfect ecclesiastical organization. It is held by some that the gospel was preached in Britain in the 1st century. Tertullian about the year 200 speaks of places in Britain which, though inaccessible to the Romans, were subject to Christ. There is no doubt that the Britons were generally converted to the Christian faith before the Saxon invasion in 449. Three British bishops were present in 314 at the council of Arles, one from York, one from London, and one from Caerleon in Wales; showing that the church was regularly organized at that date. There were also British bishops in the councils of Sardica in 347, and of Rimini in 359; and about the close

of the 3d century St. Alban suffered martyrdom during Diocletian's persecution. In the middle of the 5th century the Saxons arrived, and in the course of the century following they had nearly exterminated Christianity except in Wales and Cornwall. In 596 the monk Augustin came as a missionary from Gregory I., bishop of Rome, and found Bertha, the queen of Ethelbert, a Christian; and with the help of the remnant of the church still in the west and in Wales, Christianity was soon reestablished. Augustin found seven bishops in Wales, with whom he held conferences in the effort to bring them into conformity to the church of Rome. The British Christians, however, like the Greeks, celebrated Easter on the third day after the 14th of the Jewish month Nisan, whatever day of the week that might be (see EASTER), and practised baptism by trine affusion, and could not be induced to conform their practice to that of the Latin church at that date. These facts are emphasized by those who hold that the Anglican church was always really independent of Rome, and at the reformation simply resumed her position as a free national church. In the course of a few generations, however, the Roman supremacy prevailed, and secured a general conformity of doctrine and usage. Monastic houses were established, exempt from local ecclesiastical jurisdiction, and subject only and directly to the pope. The Norman conquest also contributed largely to the influence of Rome. The contests between the conquering Normans and the conquered Saxons continued until they were settled by the accession of Henry I. and Matilda of Scotland; and after that the struggle between the king and his barons contributed to the same result, as both parties appealed to the powerful help of the bishop of Rome. The papal supremacy was most complete when King John resigned his crown into the hands of the pope, and received it back to be held by him on condition of an annual payment. From this period there was no absolute rejection of the papal authority, although there were occasional disturbances and protests, growing stronger and more influential until the opinions of Wycliffe had leavened the Anglican church. Henry VIII. had married Catharine of Aragon, the widow of his brother Arthur, but began to question the legality of his marriage. The nation was also anxious about the succession to the throne, and Henry wished to prepare the way for a union with Anne Boleyn, and requested the pope to declare his first marriage null *ab initio*, or to grant a divorce. The pope not complying, he referred the matter, by the advice of Thomas Cranmer, to his own clergy, among whom, as well as from some foreign universities, he received opinions favorable to his wishes. Cranmer, who had been made archbishop of Canterbury, now proclaimed the king's marriage with Catharine void, and confirmed his union with Anne Boleyn, whom he had privately wedded

a few months before. The pope threatened the king with his heaviest censures, but Henry resolved to throw off the papal supremacy, and measures were at once taken to subject the clergy exclusively to the crown. A blow had already been struck at the old ecclesiastical system by the indictment of the English clergy in 1531 for supporting Wolsey in his powers as legate before receiving the royal sanction; and in the convocation held immediately after, in which a sum of money was voted to the crown by way of buying immunity from the consequences of conviction on this charge, the king was acknowledged to be "the one protector of the English church, its only and supreme lord, and, as far as might be by the law of Christ, its supreme head." By the same assemblage his marriage with Catharine was declared null, and in 1532 the parliament passed an act against paying to the pope the annates, or year's revenue of all bishoprics that fell vacant, which had formerly been paid to Rome as a tax on bulls issued to new prelates. At the same time it was ordained that no regard should be paid to censures which the pope might pass on account of this law, and that mass should be said and the sacraments administered as usual. In 1534 still more important measures were enacted. All payments made to the apostolic chamber, all bulls and dispensations were abolished; monasteries were subjected to royal government and visitation, and exempted from all other; the right to summon convocations, approve or reject canons, and hear appeals from the bishops, was vested in the king alone; and sentence of deposition was passed upon Campeggio and Ghinucci, bishops of Salisbury and Worcester. Though now honored with the title of supreme head of the church on earth, Henry contemplated no change in the doctrines of the church as then held, and no setting up of a rival community. Indeed, it was not until 30 years or more after these steps that the Roman Catholics and the reformers were looked upon as separate bodies, or had separate ministrations and separate places of worship. Throughout Henry's reign much less was done toward a change in creed or ritual than during the short reign of his son, Edward VI. The fundamental principle avowed from the first to the last, however, was that, besides retaining the ministry and the creeds of the primitive church, they must in all points of doctrine and discipline also accept its authority. In this view the offices of devotion were expurgated of what were deemed errors and innovations, and translated into English (having been previously used in Latin), and brought together as a "Book of Common Prayer and Administration of the Sacraments," in 1548-'9. A "Book of Homilies" was prepared in 1540 and 1547, to be read in all the churches for the instruction of the people; the Bible also was translated, and not only read in public worship by the clergy, but copies were placed at the public expense in

the churches, where they were accessible at all times. The details of this great change, and the growth and change of opinion among the people, appear in the lives of Sir Thomas More, Wolsey, Fisher, Thomas Cromwell, Cranmer, Latimer, and Ridley, and in the "Bishop's Book, or the Godly and Pious Institutions of a Christian Man" (republished in 1543 and called the "King's Book," because issued by royal authority), and the "Book of Articles, devised by the King's Highness Majestie to stablyshe Christen Unitie." The "Forty-two Articles" (afterward the "Thirty-nine Articles"), drawn up under Edward, summarize the views of the church of England in regard to her position, and her refusal to submit to the corruptions and assumptions of Rome. On the death of Edward VI. Mary, daughter of Henry VIII. and Catharine of Aragon, Henry's first wife, ascended the throne. She was a devout adherent of the papal authority, and set herself to secure its recognition in England. To prepare the way for the realization of her object, an important change was made in the position of the bishops. Some were declared to be no bishops, because they were married men; some were deprived of their sees because they had been appointed to them only during the good pleasure of the king. Five were condemned and burned at the stake, among the 280 martyrs who perished during this reign. Thus under Mary's rule the state again became Roman Catholic; but in about five years she died, and was succeeded by Elizabeth, the daughter of Henry and Anne Boleyn, who brought back the reformed faith and usages. The "Act of Uniformity," passed in the first year of her reign, restored the "Book of Common Prayer." All the bishops except one, Kitchen of Llandaff, refused to take the oath of uniformity, and were ejected from their sees to the number of 14; the 11 remaining sees were vacant by death. Their places were filled, though with some difficulty; but of the 9,400 beneficed clergy fewer than 200 gave up their livings. In 1563 the XXXIX articles were finally reviewed and subscribed. There was a continual struggle between the Calvinistic Puritans and the more conservative churchmen. Toward the close of the reign of Elizabeth her favorite archbishop, Whitgift, drew up, in concert with the bishop of London and other theologians, the instrument known as the "Lambeth Articles," which is strongly Calvinistic. On the other hand, the Hampton Court conference, January, 1604, although formally an attempt to satisfy the Puritans, in fact decided every important point against them. In the reign of Charles I. the ecclesiastical administration was principally directed by Archbishop Laud, whose opposition to the Puritans was manifested in the persecutions of the high commission. These oppressions, added to the civil oppressions of the star chamber, resulted in the overthrow and death of King Charles, and from 1653 to 1660 the church of England was practically suspended. With the restoration

of the monarchy in 1660 came the restoration of the church. The popular reaction against Puritanism was complete. The Savoy conference in 1661 failed to effect any reconciliation, and the act of uniformity in 1662 resulted in the ejection of 2,000 nonconformist or Presbyterian ministers from their livings. In 1687 James II., who was a Roman Catholic, issued the "Declaration of Indulgence," which professed to permit liberty of conscience to all his subjects, but was really in the interests of the Roman Catholics only. Of the 25 bishops, 18 refused to publish the declaration in their dioceses. Seven of them drew up a remonstrance to the king, and were summoned before the privy council and thrown into the tower. Their trial, which resulted in their acquittal, was one of the leading causes of the revolution of 1688, although on the accession of William of Orange eight of the bishops and about 400 of the clergy refused to swear allegiance to him, and became known as the "nonjurors." In the first year of the reign of William and Mary the "Toleration Act" was passed, and dissent ceased to be illegal. The violent discussions of the doctrines put forth by Bishop Hoadley in the lower house of convocation, in 1717, led to the dissolution of the convocation and the restriction of its jurisdiction. The period of strife was followed by a period of dulness and indifference, which gave occasion to the Wesleyan or Methodist movement, and the rise of the evangelical schools of Newton, Toplady, and Simeon; and this in turn led in 1833 to the publication of the "Oxford Tracts," and that effort to revive the principles and practices of the mediæval church which has been characterized as "Puseyism." These controversies have resulted within the church in the formation of three well recognized schools, known under the designations of high church, low church, and broad church. The high churchmen regard the apostolical succession, in the three orders of the ministry, as of divine authority and obligation, and the sacraments as channels of grace. With the extreme low churchmen episcopacy is rather an expedient than a necessary form of church government, while they sympathize with the general doctrinal views of the evangelicals of continental Europe. The broad churchmen are unwilling to be called a party, but stand in some degree antagonistic to both the high and low church parties, and embrace within their ranks some of the most gifted and intellectual men of the church, including a number of the extreme rationalists, and are more tolerant of difference of dogmatic belief. More recently the church has given much of its strength to works of benevolence and to the evangelization of the masses; while there has been great variety both of doctrinal opinion and of liturgical observance. Under Charles I. an unsuccessful effort was made to extend the church of England over Scotland. The act of union, which went into effect Jan. 1, 1801, united the Epis-

copal churches of England and Ireland, the church of England and Ireland being the state church, established by law in Ireland, although its adherents formed but a small minority of the Irish population. But by act of parliament which took effect Jan. 1, 1871, the Irish church was disestablished. (See IRELAND, CHURCH OF.)

—The church of England is divided into two provinces, Canterbury and York, with an archbishop in each, and under these 25 bishops. The bishop of Sodor and Man does not sit in parliament. The other English bishops constitute the spiritual peerage of England, and are appointed by the crown. Next to the archbishops rank the bishops of London, Durham, and Winchester, and the others take rank according to the date of their consecration. In 1872 there were 12,837 benefices in England and Wales. The church rates amount to more than £500,000, but are no part of the ministers' endowment, being devoted exclusively to the repairs and incidental expenses of the churches. New parishes, which are frequently formed out of old and over-populous ones, are for the most part very slenderly endowed. The old benefices are rectories, where the incumbent receives the great or corn tithes, or vicarages, where he receives the small tithe only. The great tithes had been bestowed formerly upon the neighboring monasteries, and at their dissolution were given to laymen and to endowed colleges. The total annual revenue of the church property in 1830 was £3,192,885, of which less than £1,000,000 belonged to the Irish branch. The average joint support of incumbents and curates is now about £300 per annum. An ecclesiastical commission was appointed in 1836, and some approach made toward converting the income of the church into a common fund, with a distribution to be made according to the wants and necessities of each office. The incomes paid to the bishops range from £15,000 to the archbishop of Canterbury to £2,000 paid to the bishop of Sodor and Man; the aggregate of the episcopal incomes being (in 1872) £154,200. There are 30 deans with incomes ranging from £3,000 (Durham) to £700 (Bangor). As assistants of bishops there were (in 1872) 72 archdeacons, and under them were 563 rural deans. The clergy of every class were estimated at 18,000. The number of parishes is about 12,000; and the aggregate number of sittings in all places of worship in 1872 was 5,701,700. The official census of England gives no information regarding the numerical strength of the population connected with the church of England, and the estimates differ considerably. In Martin's "Statesman's Manual" for 1873 it is estimated at 12,700,000, or only little more than one half; in Ravenstein's "Denominational Statistics of England and Wales" (London, 1870), at 77·8 per cent. of the total population, which according to the census of 1871 would be 17,781,000. Nearly all writers on this subject agree that the church of England has been during the

last 20 years steadily losing ground. While the number of dioceses in England has long been stationary, that of the colonial and missionary bishops has of late rapidly increased. The first colonial see established was that of Nova Scotia, in 1787; next came Quebec, in 1793. The first East Indian see was that of Calcutta, founded in 1813; the first West Indian, that of Jamaica, 1827; the first Australian see (Sydney) was established in 1836; the first of South Africa in 1850. In 1873 there were 54 colonial and missionary dioceses in connection with the church of England. Of these, 5, Bombay, Calcutta, Colombo, Labuan, and Madras, were in the East Indies; 5, Antigua, Barbadoes, Jamaica, Nassau, and Trinidad, in the West Indies; 2, Guiana and Falkland islands, in South America; 9, Cape Town, Graham's Town, St. Helena, Natal, Mauritius, Central Africa, Orange River State, Eastern Africa, and Madagascar, in south and east Africa; 2, Sierra Leone and Niger, in west Africa; 10, Adelaide, Bathurst, Brisbane, Goulburn, Grafton and Armidale, Melbourne, Newcastle, Perth, Sydney, and Tasmania, in Australia; 10, British Columbia, Fredericton, Huron, Montreal, Newfoundland, Nova Scotia, Ontario, Quebec, Rupert's Land, and Toronto, in British North America; 6, Christ Church, Nelson, Auckland, Wellington, Whaiagna, and Dunedin, in New Zealand; the remainder were the dioceses of Melanesia in the Pacific, of Honolulu in the Hawaiian islands, of Victoria in Hong Kong, of Gibraltar, and of Jerusalem. Besides the church of Ireland, also the Episcopal church of Scotland and the Protestant Episcopal church of the United States agree in doctrine with the church of England. (See EPISCOPAL CHURCH.)

ENGLAND, Language and Literature of. The English is preëminently a composite language, made up mainly from the Celtic, Latin, Anglo-Saxon, Danish, and Norman French, with the addition of words from the Greek and many other languages, ancient and modern. For the investigation of this subject there are two modes. One is linguistic, and is more strictly philological. The affinities and diversities of the various words in the language furnish the internal evidence of the several sources from which the vocabulary and the constructions were derived. The other mode, which is ethnological, and which furnishes the external evidence from the history and migration of nations, often conducts to the same conclusions with the linguistic method. When, for instance, we hear of a stream called *Wansbeck-water*, and know that each of the three words of which the name is made up signifies "water," the first in the Celtic, the second in the German, and the third in the English, we recognize three changes of inhabitants, to whom the former name successively lost its significance. This is internal evidence. We also know from history that the Celts, the Saxons, and the English have successively occu-

pied the territory where that stream is found. This is external evidence. Both kinds of evidence in this case conduct us toward the conclusion that the Celts and Saxons contributed materials to the formation of the language.—*The Celtic Element.* In the English vocabulary are found basket, from the Celtic *bagged*; mattock, from *matog*; pail, from *paol*; and other words of like derivation. Moreover, a large part of the names of the mountains, lakes, and rivers in the British isles are significant only in some Celtic dialect. The Celts emigrated westward from central Asia in the early ages. They were probably pressed onward by other tribes, until they reached the seaboard and passed over the English channel into Great Britain. Their descendants are still found in Wales and in Cornwall, as well as in Ireland, in the highlands of Scotland, in the isle of Man, and in Brittany. The English language has few Celtic words, and no Celtic constructions.—*The Latin Element.* In the English vocabulary are found street, from the Latin *stratum*; master, from *magister*; state, from *status*; April, from *Aprilis*; and many other words of like derivation. The Romans under Julius Cæsar invaded England, 55 B. C., and afterward under Agricola completed its conquest. The forms *caster*, *cester*, and *chester*, which appear so frequently in the names of places, as Lancaster, Worcester, and Winchester, are merely the Latin *castra*, camp, and show that the Romans held military possession of the whole country, establishing their fortified camps in the most favorable positions, around which in time grew up towns and cities. Roman law and magistracies were everywhere established, and the Christian religion was introduced by those who spoke the Latin language. But for the most part the Latin words in the language were not introduced during the 400 years that the Romans had possession of Britain, but afterward, while the Anglo-Saxons bore sway, or later still. A large number of Latin words were introduced by monks and learned men, relating to theology and science. Words of Latin origin constitute a very important part of the language, whether introduced directly or through the Norman French. The following is the development of the Latin portion of the language: 1, stem verbs, or roots, as *bib*, *carp*, *cede*, *urge*; 2, stem adjectives, as *bland*, *brute*, *brev* (short); 3, stem substantives, as *arc*, *barb*; 4, primary derivatives, as *final*, *factor*; 5, secondary derivatives, as *valuable*, *moderate*; 6, derivative words with prefixes, as *abode*, *allude*; 7, compound words, such as *leopard*.—*The Anglo-Saxon Element.* Whether we take into view the number or the sorts of words, the Anglo-Saxon is less an element than the mother tongue of the English. In the English language there are about 38,000 distinct words, of which some 23,000 in common use are from this source. The names of the greater part of the objects of nature, as *sun*, *moon*, *day*;

all those words which express bodily action, as *to stand*, *to stagger*; all those words which are expressive of the earliest and dearest connections, as *father*, *mother*, *brother*, *sister*, are Anglo-Saxon. Most of those objects about which the practical reason is employed in common life, nearly all English pronouns, a large proportion of the language of invective, humor, satire, and colloquial pleasantry, are Anglo-Saxon. English grammar is occupied almost exclusively with what is of Anglo-Saxon origin. The English genitive, the general mode of forming the plural of nouns, and the terminations by which we express the comparative and the superlative of adjectives (*er* and *est*), the inflections of the pronouns and verbs, and the most frequent termination of adverbs (*ly*), are all Anglo-Saxon; so are the auxiliary verbs. In fact, the Anglo-Saxon imparted so much of itself to the language, that the proximate origin of our tongue is to be sought in Germany, and its remote origin in central Asia, where was spoken the primitive tongue which may be regarded as the parent of the affiliated Indo-European languages, spoken by the successive tribes which migrated westward into Europe. The natural development of the Anglo-Saxon portion of our language has been nearly as follows: 1, instinctive forms and pronominal elements, as *ah*, *oh*; 2, stem words or roots, as *bend*, *swim*; 3, stem nouns, as *blank*, *band*; 4, reduplicate forms, as *chit-chat*, *sing-song*; 5, primary derivatives, as *chatter*, *toilsome*; 6, secondary derivatives, as *carefully*, *tiresomeness*; 7, words with prefixes, as *arise*, *forbid*; 8, compound words, as *earthquake*, *pick-purse*; 9, disguised compounds and derivatives, as *daisy*, *not*.—*The Danish Element.* Many hundred words, especially names of places, are Danish, introduced during the incursions and occupation of England by the Danes. A portion of these words are provincial, being confined to the northern and northeastern counties of England, the regions most exposed to Danish visitation.—*The Anglo-Norman Element.* An etymological analysis of the language shows that the Anglo-Norman element enters very largely into its composition. This element, which is composed of the Celtic, the Latin, and the Scandinavian, was first introduced (1066) by the Normans, under William the Conqueror. Norman French was spoken by the superior classes in England from the conquest to the time of Edward III. (1327). The laws and the proceedings in parliament and in courts of justice were in that language. In the 13th century, during the progressive mixture of the two races, a literature sprang up in which the two languages were more or less blended. In the 14th century the Anglo-Saxon element seemed to have gained the upper hand. In the 15th the Anglo-Norman seemed to be gaining the preponderance; but the proportions still continued to vary until it became fixed in the age of Elizabeth. Words were generally adopted into the common lan-

guage from the Anglo-Norman or the Anglo-Saxon, according as the objects or ideas expressed by those words belonged more exclusively to one race or the other. Thus the names of common articles of dress are Anglo-Saxon, as *shirt, breeches, hose, shoes, hat, cloak*; but other articles subject to changes of fashion are Anglo-Norman, as *gown, coat, boots, mantle, cap, bonnet*. The word *house*, a common residence, is Anglo-Saxon; but *palace, castle, manor, and mansion* are Anglo-Norman. The names *ox, calf, sheep, pig, boar* are Anglo-Saxon, because that part of the population were engaged in tending those animals while they were living; but *beef, veal, mutton, pork, venison* are Anglo-Norman names, because that part of the population were accustomed to eat their flesh when they were killed. The natural development of the Anglo-Norman or Romanic portion of the language is nearly as follows: 1, verbal roots in English, as *boil, cay* in decay, *ceive* in conceive, *pound, couch*; 2, stem adjectives, as *chaste, clear*; 3, stem substantives, as *beast, peace*; 4, derivative words with suffixes, as *flourish, authorize, volunteer, arabesque, plumage, journal, service, fashion*; 5, derivative words with prefixes, as *arouch, antechamber, countermark*; 6, Romanic compounds, as *portfolio, wardrobe*; 7, disguised Romanic words, as *biscuit, bachelor, proctor, curfew*. The common statement is that Anglo-Saxon was converted into English: 1, by contracting and otherwise modifying the pronunciation and orthography of words; 2, by omitting many inflections, especially of the noun, and consequently making more use of articles and auxiliaries; 3, by the introduction of French derivatives; 4, by using less inversion and ellipsis, especially in poetry.—Besides the languages already mentioned which have contributed to the composition of the English, several others, and especially the Greek, should also be mentioned: 1, Greek verbal roots, as *arch*, in archetype, *graph* in graphic; 2, stem adjectives, as *kul*, beautiful, in calligraphy, *kryph*, hidden, in apocrypha; 3, stem substantives, as *rhomb, cord*; 4, derivative words with suffixes, as *poet, chrism*; 5, secondary derivatives, as *Baptist, Christian*; 6, derivative words with prefixes, as *apoplexy, catarrh, catastrophe*; 7, compounds, as *democracy, pedagogue*. There are also in the language Hebrew words, as *manna*, a gum, *jasper*, a precious stone, *sabbath*; Spanish, as *querilla, matadore*; Italian, as *stanza, piazza*; Persian, as *bazaar, chess*; Arabic, as *alembic, gazelle*; Chinese, as *chop, hyson*; and Indian, as *hominny, moccason*. Our terms in polite literature come from Greece; in music and painting, from Italy; in cookery and war, from the French; and in navigation, from the Flemings and Dutch.—From its composite character, the English is copious in its vocabulary and phrases. There are large classes of words derived from the Norman or the classical languages which are in common parlance sy-

nonymous with words derived from the Anglo-Saxon. General terms are from the Latin; those that denote the special varieties of objects, qualities, and modes of action are from the Anglo-Saxon. Thus, *color* is Latin; but *white, black, green* are Anglo-Saxon. It has been remarked that "Latin furnishes the elegant, the Saxon the common expression, as *bad odor* and *stench, perspiration* and *sweat*." In looking through the several stages of the language, namely, the Saxon, the semi-Saxon, the old English, the middle English, the modern English, we are struck with the constant death of old words, and the constant birth of new ones that come in to fill their places. In the early periods this was due to the successive interruptions of foreigners, who in introducing their own language necessarily expelled a portion of the vernacular. Another cause of these mutations is that the pursuits of the English people have been multiform beyond those of any other nation, and the language has correspondingly changed. Lexicographers, in their zeal to introduce new words, to the neglect of old ones, have contributed to the changes by recording the one class and omitting the other. In Halliwell's "Dictionary of Archaic and Provincial Words" there are more than 50,000 words not recorded in modern dictionaries.—For further information on this subject the reader may consult Grimm's *Deutsche Grammatik* (4 vols., Göttingen, 1819-'37); Guest's "History of English Rhythms" (London, 1838); Rask's "Anglo-Saxon Grammar," translated by Thorpe (London); Bopp's "Comparative Grammar," translated by Eastwick (3 vols. 8vo, London); Trench's "English, Past and Present" (New York ed., 1855), and "Study of Words" (New York ed., 1861); Gould Brown's "Grammar of English Grammars" (New York, 1857); Latham's "Hand-Book of the English Language" (New York ed., 1857); Fowler's "English Language in its Elements and Forms" (New York, 1859); G. P. Marsh's "History of the English Language" (New York, 1862); Alford's "Queen's English" (London, 1864); Earle's "Philology of the English Language" (Oxford, 1867 and 1871); March's "Comparative Grammar of the Anglo-Saxon" and "Introduction to Anglo-Saxon" (New York, 1870); Stormonth's "Etymological Dictionary of English" (Edinburgh and London, 1871); Morris's "Historical Outlines of English Accidence" (London, 1872); and R. G. White's "Words and their Uses" (New York, 1870 and 1873).—ENGLISH LITERATURE was preceded in the British islands by compositions in the Cymric or ancient British, Anglo-Saxon, Anglo-Norman or early French, and Latin languages. A few Cymric metrical pieces are extant, which date probably from the 6th century; they are the songs of the Welsh bards Aneurin, Taliesin, Llewarch-Hen, and Myrddin, the sage as well as poet, whom succeeding centuries transfigure into the enchanter Merlin. To Gildas, a brother

of Aneurin (or in the opinion of some identical with him), is attributed a Latin prose tract, *De Excidio et Conquestu Britanniae*, which if genuine is the earliest historical work produced in Britain that has been preserved. The personages mentioned in these eldest British songs and annals, as Arthur, Merlin, Kay, and Gawain, played prominent parts in romantic literature a few centuries later, and still afford favorite themes for the poets. During the Anglo-Saxon period both a vernacular and a Latin literature were cultivated, their most flourishing era being the 8th century, the age of Alcuin, Aldhelm, Bede, and Ceolfrid. The monasteries of England and Ireland sent forth many scholars of European celebrity for learning, and Alcuin and Erigena served especially to associate these countries with the continent in liberal studies. The alliterative, unrhyming versification of the Anglo-Saxons was employed in some of the early English poems. But the Norman conquest almost abolished the use of Anglo-Saxon in writing, and for more than a century the prevalent literature of England was either in Latin or in Anglo-Norman. Lanfranc and Anselm, who were attracted from France by the conqueror, and became successively archbishops of Canterbury, originated or revived the scholastic philosophy, the treatises on which were in Latin, and several of the most eminent later doctors of which, as Alexander of Hales, Duns Scotus, and William Occam, were of British birth. Roger Bacon is especially remarkable for his acquaintance with Hebrew and Arabic literature, and quotes from ten of the most highly reputed Saracen authors. In connection with him may be mentioned Michael Scotus, the wizard of the northern ballads, whose writings were celebrated throughout Europe. The scholastic writers of the 12th century prided themselves on their epistolary style, and many collections of their letters have been preserved, which are among the most valuable illustrations of the public and private history of the time. These letters begin with Lanfranc, were very numerous in the reign of Henry II., and among the most interesting of them are those of Peter of Blois, which contain graphic descriptions of the manners and characters of the time. Latin poems abounded throughout the 12th century, and those of Laurence of Durham, John of Salisbury, John de Hauteville, Nigelus Wirker, and Alexander Neckham contain passages of almost classic elegance. The most ambitious attempts were by Joseph of Exeter, who wrote two epics in heroic measure. A new style of versification, in which rhymes took the place of the ancient metres, was introduced, and soon attained an attractive energy and sprightliness. It was brought to perfection in the satirical poems attributed to Walter Mapes, which exhibit excellent sense and humor amid bacchanalian jovialities. In his *Confessio Goliæ* is found the famous drinking song beginning *Meum est pro-*

positum in taberna mori. This kind of poetry became extremely popular, and flourished long after the style of the more serious Latin authors had become hopelessly debased. But the most important Latin works during the Norman period were the chronicles or histories, all of them by ecclesiastics. The chronicle of Ordericus Vitalis, which comes down to 1141, was the first in which history was made an object of laborious research; that of William of Malmesbury is the most elegant, and that of Geoffrey of Monmouth exerted the greatest influence on subsequent literature, becoming one of the cornerstones of romantic fiction. It narrated Welsh and Armorican traditions of British history from Brutus, an imaginary son of Æneas, to Cadwalladr in the 7th century. Ingulphus, Henry of Huntingdon, Giraldus Cambrensis, Roger de Hoveden, Matthew Paris, and Jocelin de Brakelonde are perhaps the other most important names in the long catalogue of monkish chroniclers. The earliest Anglo-Norman compositions extant are supposed to belong to the first part of the 12th century. In the reigns of Stephen and Henry II. a school of poets was formed devoted to versifying history in that language, the three great masters of which were Wace, Gaimar, and Benoît de Sainte-Maure. Wace translated Geoffrey's British history into Anglo-Norman verse, under the title of the *Roman de Brut*, which extends to over 15,000 lines; and also wrote the *Roman de Rou*, giving the legends concerning Rollo the Norman. Gaimar made a metrical continuation of the narrative of Geoffrey for the Norman period; and Benoît composed a romance of the history of Troy, which upheld the claims of several of the western nations to a Trojan origin. The cycle of romances relating to Arthur and the round table were prevalent in England from the 11th to the 14th century. They were in French, but several of them, as the *Merlin*, *Lancelot*, *Queste du Saint Graal*, and *Mort d'Arthur*, were written by Englishmen for the English court and nobles. Some writers have maintained also that the lays of Marie and the romances concerning Charlemagne and his paladins appeared in England earlier than in France. The original source of these fictions, and of romantic poetry in Europe, is attributed by Bishop Percy to the Scandinavians through the Normans, by Warton to the Arabians through the Moors of Spain, and by Ellis and Turner to the inhabitants of Armorica or Brittany.—During this prevalence of Latin and Anglo-Norman literature the Anglo-Saxon language had been confined to the conquered race, but the "Saxon Chronicle" had been carried on in obscure monasteries by various annalists to the year 1154. About 50 years later, when the two races began to unite in one nation, a work appeared written in Anglo-Saxon so much modified by French that it is usually accounted the beginning of English literature. This was

Layamon's translation of Wace's *Roman de Brut*, which was followed in the 13th century by many translations from Latin and Anglo-Norman. The older chronicles were more or less closely followed in the English metrical pieces of Robert of Gloucester and Robert Manning, a monk of Bournes. The Anglo-Norman romances were reproduced in the English metrical romances of "Sir Tristrem," "Sir Perceval of Galles," "Ywayne and Gawayne," "Havelok the Dane," "King Horn," "Cœur de Lion," "King Alesander," "Morte Arthure," "Sir Guy," the "King of Tars," and many others. "Sir Tristrem," one of the oldest, was attributed by Sir Walter Scott, on grounds now generally admitted to be unsatisfactory, to the Scottish poet Thomas the Rhymer. The body of Latin tales entitled *Gesta Romanorum*, perhaps of German origin, was now and continued much later to be a source of materials for English authors. The first original English poet, who left the beaten track of translation from chronicles, romances, and legends of the saints, was Laurence Minot (about 1350), the author of some short ballad-like poems on the victories of the English armies in the reign of Edward III. Richard Rolle, a hermit of Hampole, produced about the same time a moral poem entitled "The Pricke of Conscience." The most remarkable production before the age of Chaucer is "The Vision of Piers Ploughman," ascribed to Robert Langlande. It is in alliterative verse, without rhyme, abounds in allegorical personifications, and is a satire on the vices of the times and especially of the ecclesiastics. It has passages of humor and extraordinary poetical vigor, but the author adopted an obsolete and unrefined diction. Its popularity caused many imitations to be made of it, the best of which was "Piers Ploughman's Crede." Contemporary with Chaucer was Gower, whose *Confessio Amantis*, in octosyllabic metre, is a collection of stories and of physical and metaphysical reflections. Chaucer calls him the "moral Gower," and his poetry is of a grave and sententious turn, professedly serious and instructive. Both in genius and style he is much inferior to Chaucer (died in 1400), the first great English author, admirable for the comprehensiveness and variety of his powers. A courtier and traveller, he was one of the earliest English writers who was not an ecclesiastic, and he excels especially in narrative and in portraiture of character. He introduced and employed with facility the regular iambic pentameter, or heroic couplet, the most approved English metre. The prologue to the "Canterbury Tales" is unsurpassed as a description of character and manners, and the "Knight's Tale" is among the noblest of chivalrous romances. Chaucer has been compared to the appearance of a genial day in spring, preceded and followed by dark clouds and wintry blasts. After him there is a barren period of more than a century; an age of dis-

puted successions and civil wars, when, says an old historian, "the bells in the church steeples were not heard for the sound of drums and trumpets." Till the accession of Elizabeth, the best of numerous versifiers are John the Chaplain, Oecleve, Lydgate, Haws, Skelton the laureate, his rival Barclay, the earl of Surrey, Sir Thomas Wyatt, George Gascoyne, Thomas Tusser, and Thomas Sackville, afterward Lord Buckhurst. Of this series, Surrey (died in 1547) is most esteemed as an improver of English verse. He is said to have made the tour of Europe in the spirit of chivalry, proclaiming the unparalleled charms of his mistress Geraldine, and returned to England distinguished as the most devoted lover, learned nobleman, and accomplished gentleman of his age. In his verses he copied the simplicity and grace of the Italian poets, avoiding learned allusions or elaborate conceits, and naturalized the sonnet in England. He also gives the earliest example of blank verse. Wyatt co-operated with him in seeking the elegances of composition; but he embarrassed his songs and sonnets with witty and fanciful conceits. John Heywood is remembered only for his interludes, but he wrote also 600 epigrams, and his most labored performance, "The Spider and the Flie," is pronounced by Warton to be the most tedious and trifling of apologues, without fancy, meaning, or moral. A remarkable poem of this time is the "Mirrour for Magistrates," written by a combination of authors, the chief of whom was Sackville. He furnished alone its most valuable portion, the "Induction" or prologue, an imitation of Dante, marked by a monotony of gloom and sorrow, but showing both grandeur of imagination and power of language. Spenser's "Faerie Queen" appeared in 1590. He had already established his reputation by his "Shepherd's Kalender," published the year before. The "Faerie Queen," although unfinished, is really complete in its first book, every canto of which teems with beauties. The following books are altogether inferior, and are rather supplementary, personifying the struggles of the virtues with their opposite vices. The poem, after the fashion of the reign, flatters Elizabeth under the characters of Gloriana and Belphebe. Its peculiar stanza, to which Spenser's name has been given, a modification of the Italian *ottava rima*, with the addition of an Alexandrine to give a full and sweeping close, was an innovation in the art of poetry, and has since been much used. Contemporary with Spenser was Sir Philip Sidney, whose songs and sonnets deserve mention; and either contemporary or soon following were the "Saint Peter's Complaint" and "Mary Magdalene's Funeral Tears" of Robert Southwell; the "Civil Wars," "Complaint of Rosamond," and numerous minor pieces of Samuel Daniel, of a pensive character, and in remarkably pure style; the "Barons' Wars" and the "Poly-olbion" of Michael Drayton, the former a metrical chronicle, and the latter

an immense piece of metrical topography, which contains also striking national legends and ingenious allegorical and mythological inventions; the few and brief poems of Sir Henry Wotton; the *Nosce Teipsum* and the "Orchestra" of Sir John Davies, the former a happily condensed piece of metaphysical reasoning; the satires of Bishop Hall, published in 1597, the earliest in the language except the "Steele Glas" of Gascoyne; the satires, elegies, and various lyrics of John Donne, which are rather metrical problems than poems, strongly manifesting the metaphysical tendency then common in poetry, but which reveal a subtle intellect and fruitful fancy, though obscure in thought, rugged in versification, and full of as bad affectations and conceits as are to be found in the century; the poems of the brothers Phineas and Giles Fletcher, the principal of which are "The Purple Island," an allegorical description of the human soul and body, and "Christ's Victory and Triumph," a beautiful religious composition; and the sacred poems of the country parson, George Herbert. The ballad literature of England and Scotland is of uncertain date, but much of it, as "Chevy Chase," "The Nutbrowne Mayde," and the numerous ballads about Robin Hood, probably arose in the 15th and 16th centuries. Its golden era was the time of Mary, queen of Scots. Scotland meanwhile had a succession of genuine poets, Barbour (died about 1396), who wrote an epic entitled "The Bruce," having been followed by Wyntoun, Blind Harry, Gawin Douglas, and William Dunbar. —The annals of the British drama begin with miracle plays, which are first mentioned as being represented in London in the latter part of the 12th century. They were on sacred subjects, usually from the Bible, were written and to a late period acted by ecclesiastics, and were at first performed in churches and the chapels of monasteries. They were performed on holy days in the largest towns, the most famous and frequented being those of Chester, Widkirk, and Coventry. At Chester they continued every Whit-Sunday, with some interruptions, from 1268 to 1577, and were in Latin or French till in 1338 Higden "obtained leave of the pope to have them in the English tongue." The most ancient extant miracle play in English is at least as old as the reign of Edward III. It is founded on the 16th chapter of the apocryphal gospel of Nicodemus, is entitled "The Harrowing of Hell," and consists of a prologue, epilogue, and intermediate dialogue between nine persons, among whom are Dominus, Satan, Adam, and Eve. Besides this and a few other single pieces, there are three distinct sets of them: the Townley collection, 30 in number, supposed to have belonged to Widkirk abbey, before the suppression of the monasteries; the Coventry collection, performed in that city on the feast of Corpus Christi, 42 in number; and the Chester Whitsun collection, 30 in number. Miracle

plays were transformed into moral plays by exchanging Scriptural and historical characters for abstract, allegorical, or symbolical impersonations. This sort of religious drama was in a state of considerable advancement in the reign of Henry VI., and reached its highest perfection in that of Henry VII. Two prominent personages in them were the Devil and a witty, mischievous, profligate character, denominated the Vice. "By the relinquishment of abstract for individual character," says Mr. Collier, "they paved the way, by a natural and easy gradation, for tragedy and comedy, the representations of real life and manners." John Heywood, the epigrammatist, who belonged to the court of Henry VIII., contributed to driving Biblical and allegorical personages from the stage, and his plays form a class almost by themselves, termed interludes. The later plays of Bishop Bale also belong to the period of transition, and he was the first to apply the name tragedy and comedy to English dramatic representations. The earliest comedy is the "Ralph Roister Doister" of Nicholas Udall, and is at least as ancient as the reign of Edward VI. It has 13 characters, 9 male and 4 female, represents the manners of polished society, and could not be performed in less than 2½ hours. It is superior to "Gammer Gurton's Needle," by John Still, the second in point of time, which was acted at Cambridge university in 1566, and contains the first drinking song of any merit in the language. The earliest extant piece that can be called a tragedy is the "Ferrex and Porrex" of Thomas Sackville and Thomas Norton, afterward named "The Tragedy of Gordobuc," which is in regular blank verse, consists of five acts, and was played before Queen Elizabeth at Whitehall, Jan. 18, 1562. During a part of the reign of Elizabeth miracle plays, moral plays, and romantic dramas were prevalent together. The custom of acting Latin plays in the universities of Oxford and Cambridge continued till Cromwell's time.—From the middle of the reign of Elizabeth to the accession of Anne (1580–1702), and more particularly to the great rebellion (1580–1642), may be reckoned the period of the so-called old English authors. The more limited era is unsurpassed in force, variety, and originality of literary genius in the annals of the world. Among the influences which excited vast intellectual and moral activity were the study of the classics and of the literatures of Italy and France, the discovery of America and of the true theory of the solar system, the reformation, the practical results then following from the invention of gunpowder and of printing and from the overthrow of feudalism, the assertion of individual rights, and the enthusiastic sense of national independence and power. New ideas and interests aroused the minds of men, and the old forms and institutions, disappearing from actual life, lingered in the imagination and were idealized in poetry. The language rapidly grew to a

strength and affluence which Dr. Johnson declared adequate to every purpose of use and elegance, while a masculine vigor, sometimes coarse, sometimes highly delicate, marked all the diversities of character and culture. The most extensive and important department of literature during this epoch was the drama, which distinguishes that age from all preceding and less decisively from all subsequent periods. It had two distinct periods, that of the old English dramatists (in the narrowest use of the term) prior to the civil war, and that of the comic dramatists after the restoration. In the former series the most eminent names are Marlowe, Shakespeare, Ben Jonson, Beaumont and Fletcher, Chapman, Decker, Webster, Marston, Massinger, Ford, Thomas Heywood, and Shirley. Among the precursors of Shakespeare were also John Lilly, whose nine plays, and especially "Endimion," have always had admirers for their dainty and conceited style; Thomas Kyd, whose "Spanish Tragedy," improved by Jonson, is said to have gone through more editions than any other play of the time; Thomas Nash, a ribald satirist; Robert Greene, whose comedies are lively, fantastic, and florid, and whose "Friar Bacon and Friar Bungay" is one of the latest plays in which the devil appears in person; George Peele, whose "David and Bethsabe" has been termed the earliest fountain of pathos and harmony in English dramatic poetry; and Thomas Lodge, who was associated with Greene in writing "The Looking-Glass for London and England," a strange performance, in which the prophecy of Jonah against Nineveh is applied to the city of London. All of these abound in bombast and pedantic classical allusions. A more potent spirit was Christopher Marlowe (1564-'93), who, throwing off the shackles of rhyme, gave to blank verse an easy modulation and rhythm, and amid much rant and buffoonery produced some scenes and passages of wonderful beauty and grandeur. His most admired plays are "The Jew of Malta," "Edward II.," and "The Life and Death of Dr. Faustus," the last of which best illustrates the "fine madness" of his character. An awful melancholy pervades the fiend Mephistopheles, more impressive than the malignant mirth ascribed to him by Goethe. Marlowe was the immediate precursor of William Shakespeare (1564-1616), a comparison of whose works with those of his contemporaries proves his superiority as much in judgment and taste as in creative power, for a large proportion of his plays are more regular than any other prior to the close of the civil wars. The rules of the classical dramatic art were not then in vogue; the French neo-classical drama had not been originated; and though Shakespeare violated the ancient unities of time and place, he observed almost universally the unity of feeling and of interest. The soundest criticism has vindicated for him the character of a profound artist as well as a great and luxuriant genius, and his peculiar

excellences appear in the marvellous variety and verisimilitude of his personages, in the skill with which opposite characters are grouped and the finest and most diversified threads woven into a harmonious web, and in the completeness with which the entire action as well as the several characters is worked out, minute features and particulars being poetically conceived with reference to the universal system of things. Shakespeare's plays are 34 in number (the authorship of some of which, however, is disputed), and are usually divided into tragedies, comedies, and histories. Since the beginning of the present century their supremacy has attained unqualified and intelligent recognition. A friend of Shakespeare and his associate in the Mermaid, the oldest of clubs, was Ben Jonson (1574-1637), one of the most familiar names among the old dramatists. He had scholarly acquaintance with the classics, and labored to make the laws of the ancients authoritative in English dramatic art. He is the author of two tragedies, "Catiline" and "Sejanus," and of numerous comedies and masques, the best of which are "The Alchemist," "Volpone, or the Fox," and "The Silent Woman." They are full of solid materials, in a stately, eloquent, but often pedantic style, and seem to have been produced slowly and upon deliberation, the wit, fancy, and satire being severely elaborated. His poetical character appears in its most pleasing aspect in the lyrical verses with which his masques are varied and enlivened, especially in the pastoral drama of "The Sad Shepherd," which display an admirable taste and feeling, and have all the charms of song. Jonson may have aimed at an audience of men of sense and knowledge, but Beaumont and Fletcher wrote for men of fashion and the world. Of the 52 plays published under their joint names, Beaumont may have had a part in only 17. They are keen, vivacious, and often elegant, but slight and superficial in comparison with Shakespeare's and Jonson's; the songs scattered through them are, however, among the most beautiful in the language. The dramas of George Chapman (1557-1634), the translator of Homer, contain "more thinking" than those of most of his contemporaries; they have many passages of striking grandeur, are in a lofty and extravagant style, and their contemplations on the nature of man and the world leave impressions favorable to moral excellence. The "Fortunatus" and "Honest Whore" of Thomas Decker have graceful and genial passages; and the "Duchess of Malfy" and "White Devil" of John Webster are full of horrors cleverly managed, and have been esteemed among the most striking tragic productions of this period. The modern reputation of Thomas Middleton rests chiefly on his "Witch," which may have suggested to Shakespeare the supernatural scenery in "Macbeth;" and the coarse plays of John Marston abound in murders, ghosts, and scornful satire. The tragedies of Philip Massinger (1584-1640) have

an easy and majestic flow. "The Duke of Milan" and "The Fatal Dowry" are among the best; and of his comedies, "The Picture," "The Bondman," and "A Very Woman." His "New Way to Pay Old Debts" still keeps the stage, for which it is indebted to its effective character of Sir Giles Overreach. John Ford (died about 1640) preferred dark vices and the deepest distress for subjects. He seems to have taken pleasure in revolving the various possibilities and revenges of sin, and the best of his plays bears the title of "The Broken Heart." Thomas Heywood, an indefatigable and popular dramatist, wrote "beautiful prose put into heroic metre." James Shirley (died in 1666) is the last of this circle of dramatists, and the least remarkable either for merits or faults. Under the commonwealth, and the ascendancy of the Puritans, the theatres were closed and the players flogged. Sir William Davenant tried to introduce a modification of the drama suited to the moral views of the time, but with only partial success. At the restoration the drama was revived under the influence of French rules and of a strong anti-Puritan reaction, with great mechanical improvements, movable decorations, music, and lights; but the larger part of the plays for 40 years are declared by Macaulay to be a disgrace to the English language and the national character. To ridicule and degrade virtue, sincerity, and prudence was the business of the stage. Blank verse was displaced by rhyme, but the tragic authors soon returned to the former, and the comic sank to familiar prose. The best tragedies of the period are "The Orphan" and "Venice Preserved" of Thomas Otway (1651-85); and though the former displeases the delicacy of our age, the latter has been more frequently represented than any other tragedy except those of Shakespeare. The genius of the poet appears especially in pathetic delineations of passion and misery, and few heroines have been so highly honored with the tribute of tears as Belvidera in "Venice Preserved." John Dryden, who was rivalled by none of his contemporaries as a satirical, didactic, and lyric poet, abused his rare gifts to attain dramatic success, the faculty for which nature had denied him. His "Don Sebastian," "Spanish Friar," and "All for Love" are the best of numerous tragedies and comedies, whose bombast and ribaldry have rendered them obsolete, notwithstanding their surprising incidents, stately declamation, and harmonious numbers. The "Fatal Discovery" of Southerne, the "Jane Shore" of Rowe, the "Mourning Bride" of Congreve, and the "Rival Queens" of Lee may also be mentioned among successful tragedies. The proper representatives of the comedy of this period are Wycherly, Congreve, Farquhar, and Vanbrugh, and among their profligate plays the most popular were "The Plain Dealer" and "The Country Wife," "Love for Love" and "The Way of the World," "The Beaux Stratagem" and "The Trip to the Ju-

bilee," and "The Provoked Husband" and "The Provoked Wife." Mrs. Aphra Behn, Thomas Shadwell, and Sir George Etherege also deserve mention among those who made the stage as immoral as their talents permitted. The "Careless Husband" and other plays of Colley Cibber, and the "Busy Body" and "Bold Stroke for a Wife" of Mrs. Centlivre, connect the period of the restoration with that of Anne. Among the non-dramatic poems of the Elizabethan age, mention should be made of the translation of Ovid and Lucan by Marlowe; Sandys's versions of Ovid and the Psalms; Harrington's version of Ariosto, Fanshawe's of Camoëns, and the more important versions of Homer by Chapman and of Tasso by Fairfax.—The literary genius of the age of Puritan ascendancy, between the Elizabethan epoch and that of the restoration, culminated in Milton, who has no rivals in epic poetry but Homer, Virgil, and Dante. His career illustrates the literary character of his age. Prior to 1640 he had produced "L'Allegro," "Il Penseroso," "Comus," "Lycidas," and the "Ode on the Morning of the Nativity," one of the finest in the language. During the period of civil conflict and Cromwellian rule, from 1640 to 1660, he wrote no poetry except a few sonnets, but produced his various polemical prose treatises; and it is remarkable that there was at that time an almost entire cessation of pure literature in England. The contemporary poets, without an exception of any consequence, had their eras of activity only before the struggle and after it, or in exile or in prison during it, and the intellect of the country was occupied in producing a huge mass of controversial prose, only a very slight portion of which has taken a place in the literature. One literary man only was undisturbed and uninterested by the events of the time. While England was in political and religious confusion, Sir Thomas Browne was quietly meditating in his garden at Norwich upon sepulchral urns and the quincunial lozenge. "Paradise Lost," though published after the restoration, was an early conception of Milton, and bears the impress of this period of fierce discussion and of moral and theological strife. Its subject, the fall of man, is perhaps without an equal in epic grandeur, and its most prominent personage, if not its hero, is the fallen archangel Satan, whose ruined splendor and power of daring and of suffering make him one of the sublimest creations of poetry. The latest poems of Milton, "Paradise Regained" and "Samson Agonistes," are of inferior worth. Among the contemporaries of Milton were Thomas Carew, Francis Quarles, George Wither, Sir John Suckling, Robert Herrick, Richard Lovelace, Sir Richard Fanshawe, Richard Crashaw, Abraham Cowley, Henry Vaughan, Sir John Denham, Sir William Davenant, Edmund Waller, and Samuel Butler. The songs and short amatory pieces of Carew were the precursors of numerous similar productions written by

gay and accomplished cavaliers and courtiers, as the "Ballad upon a Wedding" and many other poems of Suckling, admirable for their witty levity; the odes and songs of Lovelace; the miscellaneous poems of Fanshawe; and, superior to all others, the graceful occasional poems of Cowley and Waller. The melodious verse of Waller was especially admired, and was diligently studied by Pope. Cowley (1618-67), though full of metaphysical conceits, was the most popular poet of his time. His Anacreontics, the happiest of his pieces, are lively, joyous, and charmingly embellished. The "Cooper's Hill" of Denham is at once meditative, vigorous, and rhythmical, and the "Gondibert" of Davenant was for a time regarded as a monument of genius. The religious poems of Quarles, Crashaw, and Vaughan may be classed together. The productions of Herrick and Wither exhibit playfulness of fancy and delicacy of sentiment, varied in the former by frequent grossness and indelicacy. Butler's "Hudibras," a work of inexhaustible wit, which was perpetually quoted for half a century, belongs chronologically, as do many of the later poems of Milton and his contemporaries, to the age when Dryden (1631-1700) and the comic dramatists were prevalent. Dryden's rapidity of conception and ease of expression made him a voluminous contributor to various departments of literature. The greatest of his satires are "Absalom and Achitophel" and "Mac Flecknoe," and the first lines of his fine controversial poem, "The Hind and Panther," are among the most musical in the language. His various, though not his greatest, excellences appear in his "Fables" and his "Ode for Saint Cecilia's Day." Among his contemporaries, a few of whose poems still survive, were Marvell, Rochester, Charles Cotton, Sedley, John Philips, Oldham, Roscommon, Mulgrave, Dorset, and Pomfret.—English prose begins with Sir John Mandeville's narrative of his travels, written in Latin, French, and English, soon after his return to England in 1355. It is a medley of his own observations, with ancient fables and the marvels reported by other travellers. Nothing like the excellence of later English prose was produced for the next century and a half, during which time Trevisa translated Higden's Latin *Polychronicon*, Wycliffe began to show the copiousness and energy of the language in his translation of the Bible, Chaucer composed two of the Canterbury tales and two other works in prose, Bishop Peacock wrote in favor of reason rather than constraint as a means of bringing the Lollards within the pale of the Catholic church, Tiptoft translated Cicero's *De Amicitia*, Lord Rivers became an author by his "Diets of Philosophers," and Sir John Fortescue (died about 1480) surpassed all of his predecessors in the style of his treatise on "The Difference between an Absolute and a Limited Monarchy." The first book printed in England is supposed to have been "The Game of Chess,"

by Caxton, in 1474. As an author, by translating from the French, and often by continuing the works which he printed, Caxton probably exerted a greater influence on prose literature than any other individual between Chaucer and the reign of Henry VIII. Chroniclers nearly contemporary with him were Robert Fabyan and Edward Hall. A curious collection of letters has been preserved, written by members of the Paston family in the reigns of Henry VI., Edward IV., and Henry VII., which forms the oldest body of private letters in any modern European language. To the reign of Henry VIII. belongs Sir Thomas More's "History of Edward V.," the first example of a pure and perspicuous prose style. His *Utopia*, in which he developed his theory of a perfect society, was first published in Latin, and was scarcely excelled in spirit and originality by any previous Latin work written in Europe since the revival of letters. Prior to Elizabeth, or early in her reign, were written also the "Itinerary" of Leland, the "Gouverneur" of Sir Thomas Elyot, the "Art of Rhetorique" of Thomas Wilson, the biography of Wolsey by Cavendish (first printed in 1641), the translations of the Bible by Tynedale and Coverdale, the sermons and letters of Latimer, and the "Toxophilus" of Roger Ascham, who was the first accomplished scholar that composed his chief works in English.—The old English prose writers are generally distinguished for sterling sense, and for a style copious to redundancy. Their diction is deformed by pedantry, their collocation of words and phrases is in imitation of the Latin, and their periods are tediously prolonged and un rhythmically constructed; yet they are nervous and effective, and seldom degenerate into indefinite and aimless phraseology. The most admirable prose writer of the Elizabethan period is Richard Hooker (1553-1600), whose "Ecclesiastical Polity" is one of the masterpieces of English eloquence; and its richness of style and fullness of imagery, united with condensation of thought, was unapproached by any other writer during the next century. The *Novum Organon* of Bacon (1561-1626), the most influential and original philosophical work produced in England, was written in Latin. He compared his "Advancement of Learning," a "globe of the intellectual universe," with a note of those parts not yet improved by the labor of man, to the noise which musicians make in tuning their instruments, "which is nothing pleasant to hear, but yet is a cause why the music is sweeter afterward;" and at the close of his survey he predicted that "the third period of time will far surpass that of the Grecian and Roman learning." His style, usually sententious and somewhat stiff, became more imaginative, richer, and softer with his increasing years; but though his fancy was of the brightest, he allowed to it no other office than that of ministering to reason. His application of thought to purposes of utili-

ty and progress, with a view to the practical restitution of man to the sovereignty of nature, has entered as a characteristic element into the public mind of England. His "Essays" are among the masterpieces of English prose, and are equally eminent for power of expression and for compact and solid wisdom. Contemporary productions were the "Arcadia" and the "Defence of Poesy" of Sir Philip Sidney, the former of which was universally read and admired; the "History of the World" of Sir Walter Raleigh, written in the tower; the "Chronicle of England" and "Survey of London" of John Stow; the chronicles of Raphael Holinshed; the collection of voyages by Richard Hakluyt; the "Purchas his Pilgrims" of Samuel Purchas; the "Relation of a Journey," &c., of George Sandys; the "Epistolæ Hø-Elianae" of James Howell; the "History of the Turks" of Richard Knolles; and the sermons of Bishop Andrews and Dr. Donne, mosaics of quaintness, quotation, wisdom, folly, subtlety, and ecstasy. The writings of John Lilly produced a marked effect on much of the Elizabethan literature. His "Enphues," a dull story of a young Athenian, in a smooth style, full of affected conceits and recondite similes, was the model after which wits and gallants formed their conversation and writing. The ladies of the court were among his pupils, and Blount (1632) remarks that the beauty who could not "parley Euphuisme" was as little regarded as one that could not speak French. Under James I. was produced the translation of the Bible which is still the standard English version, and which did much to make the language of the Elizabethan age the permanent speech of the English people. Between Bacon and Locke, the most acute of English metaphysicians was Thomas Hobbes (1588-1679), whose political theories are collected in his "Leviathan." His style is uniformly excellent, a merit which belongs to none of his predecessors. Among his contemporaries were the skeptical philosopher Lord Herbert of Cherbury, who wrote also a history of the reign of Henry VIII.; the antiquaries William Camden, Sir Henry Spelman, Sir Robert Cotton, and John Speed; John Selden, the author of a "Treatise on Titles of Honor," whose admirable "Table Talk" was published after his death; the chronologist Archbishop Usher; William Chillingworth, whose "Religion of Protestants" is a model of perspicuous reasoning; Peter Heylin, a wit and divine, the author of "Microcosmus;" John Hales, a preacher and controversialist; John Gauden, the probable author of the famous "Eikon Basilike," which professed to have been written by Charles I.; and the two most eloquent of the old English divines, Joseph Hall (1574-1656) and Jeremy Taylor (1613-1667), whose works are monuments of their own abilities and of the pedantic tastes of the age. The "Contemplations" of Hall are superior to any of the writings of

Taylor in continuity of thought, but the latter has perhaps had no equal in the pulpit in the splendor of his imagination, and is often called the Shakespeare of divines. The most curious works of the time are the "Anatomy of Melancholy" of Robert Burton (died about 1640), composed largely of apt and learned quotations from rare authors, constantly intermingled with the writer's own thoughts, which exhibits in every part great spirit and power, and has the charm of a full and vigorous style; and the "Religio Medici," "Urn Burial," and other works of Sir Thomas Browne (1605-1682), elaborately quaint compositions, fascinating from their pensiveness akin to melancholy, their paradoxes, and their occasional subtlety and imaginative brilliancy. Under the head of essays or sketches may be classed the "Gull's Hornbook" of the dramatist Decker, the "Characters" of Sir Thomas Overbury, the "Resolves" of Owen Feltham, the "Microcosmography" attributed to Bishop Earle, the miscellaneous pieces of Sir Henry Wotton, and the "Discourses by way of Essays" of Cowley. The last are written in a perspicuous style, very unlike the affected obscurities of his poems, and may be reckoned among the earliest models of good writing in English prose. John Locke (1632-1704) is the author of treatises on civil government, education, and the reasonableness of Christianity, which diffused a spirit of liberty and toleration in opinion and government; but his most important work is the "Essay concerning the Human Understanding," which was for a time the acknowledged code of English philosophy, and displays and inculcates a careful, tentative observation of intellectual habits. It helped to convert metaphysics from scholastic problems into practical and clearly intelligible analyses, but its indefiniteness in the use of the phrase "ideas of reflection" has left the essential character and tendency of the Lockean system in dispute between sensationalists and idealists. Two writers who at this time deviated from the track which English speculation has chiefly followed, and in whom Platonic tendencies predominated, were Ralph Cudworth, author of "The Intellectual System of the Universe," a vast storehouse of learning and an unrivalled exhibition of subtle speculation, and Henry More, author of "The Mystery of Godliness," "The Mystery of Iniquity," and other works which were once very popular. The sermons of Barrow, South, and Tillotson were respectively esteemed for strength, wit, and unction, but the last have retained least of their former popularity. To this period belong most of the prose writings of Milton, which test the power of the language in vigorous and lofty declamation, the *Origines Sacrae* of Stillingfleet, the theological treatises of Sherlock, the "Exposition of the Creed" of Pearson, the "Exposition of the XXXIX. Articles" of Bishop Burnet, the "Saint's Everlasting Rest" and other works of Baxter, the

expository works of Leighton, Owen, and Henry, and the writings of the Quakers George Fox, Robert Barclay, William Penn, and Thomas Ellwood. This age of divines and comic dramatists was also distinguished for its devotion to practical science under the guidance of the spirit of Bacon, and chemistry and physics became at once fashionable and respected. Instances of this tendency are the "Discovery of a New World" and the other so-called "mathematical works" of Bishop Wilkins, the "History of the Royal Society" of Sprat, the "Sacred Theory of the Earth" of Thomas Burnet, the "Sylva" and "Terra" of Evelyn, the "Observations" and the "Wisdom of God Manifested in the Works of Creation" of John Ray, and above all others, the "Considerations on the Usefulness of Experimental Philosophy," and other works, philosophical and religious, of Robert Boyle, and the *Philosophiæ Naturalis Principia Mathematica* of Sir Isaac Newton. Among antiquarian works were the *Monasticon Anglicanum* of Sir William Dugdale, the *Athenæ Oxonienses* of Anthony à Wood, the history of the order of the garter by Elias Ashmole, the "Miscellanies" of John Aubrey, and the *Fœdera* of Thomas Rymer, who also wrote a curious treatise on tragedy, in which Shakespeare is criticised according to certain stately notions derived from the ancients. Works of high literary interest are the "Worthies of England" of Thomas Fuller, one of the strangest books in the world, a melange of oddity, sagacity, and humor, in a pithy style; the "History of the Rebellion" of Lord Clarendon, which, in spite of its partiality, is admirable for its portraiture of character and its animated narrative; the "Observations on the United Provinces of the Netherlands" of Sir William Temple; the histories of the reformation and of his own times by Gilbert Burnet; the "Pilgrim's Progress" of John Bunyan, a specimen of homely English, the fruit of a lively and powerful imagination cultivated only by the study of the Scriptures; and the half poetical "Complete Angler" of Izaak Walton, who also wrote some pleasing biographies. Minor works were the translations and political pamphlets of Sir Robert L'Estrange, the "Contemplations" of Sir Matthew Hale, the "Essays" on ancient and modern learning by Temple, and the "Reflections" in answer to them by Wotton. Tom D'Urfey and Tom Brown, the last of the wits of the restoration, wrote comic and licentious compositions in prose and verse. The "Short View," &c., of Jeremy Collier was the beginning of a controversy between him and the comic dramatists which resulted in the reformation of the theatre.—With the reign of Anne (1702-14) begins a new era in English composition, when the affluence of the older literature gave way to correctness. The rules of the art were better understood, the style was cleared of its redundances, and wit refined from its alloy. The writers of the Elizabethan period, in an

age of stupendous changes, on the confines between barbarism and refinement, had dealt with the original passions and principles of human nature, and had found their illustrations in the pageantry of past institutions and in dreams of the future. As the English advanced to the character of a polished nation, their literature also became less wild and grand in its romance and more regular in its outlines, the suggestions of genius being moulded by the rules of taste. As enriched and refined by the writers of the reign of Anne, which is often called the Augustan age of the literature, the language was almost finally formed. The fashions and frivolities of elegant and artificial life became the themes of poets and essayists, and while the highest regions of poetry and speculation were abandoned, books were no longer confined to the learned or curious, but were gradually spread among all classes. Men of letters now first became known in England as a distinct class in society. To bring philosophy out of closets and libraries, schools and colleges, and to make it dwell in clubs and assemblies, at tea tables, and in coffee houses, was the task which Steele proposed to himself. That school of poetry which may be traced to the adoption of French rules under Charles II., which acquired stability from the transcendent powers of Dryden, was now perfected by Alexander Pope (1688-1744), and retained its ascendancy nearly through the 18th century. The follies of his feeble copyists have reacted injuriously upon the fame of the great master of the school. For half a century the notion prevailed that whoever deviated from the standard of Pope was worthy only to figure in the "Dunciad;" but somewhat later it became common to deny to him poetic genius, imagination, and versatility, and to decry his wit, epigrammatic force, and faultless numbers, by confounding them with the imitations of those who had caught something of his metre, but nothing of his spirit. His correctness was branded as the badge of unimaginative and artificial verse, and might almost be numbered among the lost arts. Yet Campbell and Byron were zealous to do him justice, and the latter compared the poetry of the 18th century to the Parthenon, and that of his own times to a Turkish mosque. The vigor of conception and point of expression which distinguished the "Essay on Man," the "Rape of the Lock," the "Epistle from Eloisa to Abelard," the "Satires," and the "Dunciad," vindicate for them the highest rank in a peculiar and admirable class of compositions. His "Iliad" and "Odyssey," though un-Homeric, are valuable additions to English literature. The finest contemporary poetical productions were the "Letter from Italy," the "Campaign," and the "Cato" of Addison, the octosyllabic satires and occasional pieces of Swift, the "Shepherd's Week, in Six Pastorals," of Gay, the "Hermit" and the "Night Piece on Death" of Parnell, and the "Gentle Shep-

herd" of the Scotch poet Allan Ramsay. The names of Prior, Tickell, Garth, Blackmore, Ambrose Philips, Somerville, and Anne, countess of Winchelsea, also belong here. It is remarked by Wordsworth that between the publication of "Paradise Lost" (1667) and of the "Seasons" (1730) of James Thomson, with the exception of the "Windsor Forest" of Pope and a passage in the "Nocturnal Reverie" of the countess of Winchelsea, not a single new image of external nature was produced in poetry. "The Seasons" is almost the only memorial which the age has left of poetical sympathy with natural scenery. It was original as well in style as in substance, for its blank verse has an easy flow peculiar to itself. Thomson's "Castle of Indolence" is a successful imitation of the manner of Spenser, and has great and peculiar beauty. The "Night Thoughts" of Edward Young (died in 1765) is also in effective blank verse, dissertational rather than simply poetical, in a sustained imaginative and epigrammatic style. The "Grave" of Robert Blair and the hymns of Watts are serious and devotional compositions of the same time. Through the "Bastard" of Richard Savage, the "London" and "Vanity of Human Wishes" of Dr. Johnson, the eclogues and odes of William Collins, the "Pleasures of Imagination" of Mark Akenside, the odes and the "Elegy" of Thomas Gray, the "Deserted Village" and the "Traveller" of Oliver Goldsmith, the "Minstrel" of James Beattie, the "Botanic Garden" of Erasmus Darwin, and the "Task" of William Cowper, the line of English poetry was continued almost to the commencement of the present century. Johnson and Goldsmith both belonged to the school of Pope; but their poetry has distinctive characteristics, that of Johnson being marked especially by vigor and strong sense, and that of Goldsmith by sweetness and grace. The "Ode on the Passions" and several other pieces of Collins are masterpieces in their kind, and especially remarkable for the pictorial effects produced by the personification of abstract qualities. Collins and Gray were the two finest lyric poets of the century, and Gray's "Elegy written in a Country Churchyard" and his Pindaric ode of "The Bard" are exquisite examples of finished art and poetical vigor. Cowper was the precursor of the regeneration of poetry, and, abandoning the stock images and metrical sing-song with which art and fashion had been described, he produced pictures of English life and scenery marked by a simplicity, freedom, and freshness which anticipated the dawn of a new period. Among the productions of minor poets of the 18th century are the "Grongar Hill" of John Dyer, the "School-mistress" of Shenstone, the "Collin and Lucy" of Tickell, the "William and Margaret" of Mallet, the Scotch songs of Ross, the "Mary's Dream" of Lowe, the "Auld Robin Gray" of Lady Anne Barnard, the "Tullochgorum" of Skinner, the "Tweedside" of Crawford, the

various poems of Ferguson, the odes and the epitaph on his wife of Mason, the odes of Smollett, the "Art of Preserving Health" of Armstrong, the "Cumnor Hall" and the translation of the "Lusiad" of Mickle, the "Braes of Yarrow" of Hamilton, the elegies of Hammond, the "Careless Content" of Byrom, the "Country Justice" of Langhorne, the "Lawyer's Farewell to his Muse" of Blackstone, the "Shipwreck" of Falconer, the "Actor" of Robert Lloyd, the "Rosciad" and other satires of Charles Churchill, the brief poems of Thomas and Joseph Warton, the "Leonidas" and "Athenais" of Glover, the short lyrics and translations of Sir William Jones, the "Chameleon" of Merrick, the pastorals of John Cunningham, the "New Bath Guide" of Anstey, and the "Triumphs of Temper" and other works of Hayley. In the latter half of the 18th century also Macpherson produced the pieces which he ascribed to Ossian, Chatterton wrote the poems which he ascribed to Rowley, and Percy collected many old songs and ballads in his "Reliques of English Poetry."—The English drama of the 18th century bore to a considerable extent the impress of the neo-classical school reigning in France, and presented a complete separation of tragedy and comedy. The "Cato" of Addison, the "Elfrida" of Mason, and the "Irene" of Johnson are rather dramatic poems than plays. The "Sophonisba" and four other tragedies of Thomson are the undramatic attempts of a descriptive poet. More successful tragedies were the "Revenge" of Young, the "Barbarossa" of Brown, the "Gamester" of Moore, the "Elvira" of Mallet, and the "Douglas" of Home. In this period were produced the finest examples of English comedy, written usually in prose, and exhibiting refinement of sentiment and wit. The forerunners of the comedies of Goldsmith and Sheridan were the "Conscious Lovers" of Steele, the "Suspicious Husband" of Hoadley, the "Jealous Wife" of the elder Colman, the "Clandestine Marriage" of Colman and Garrick, the "Way to Keep Him" of Murphy, the "False Delicacy" of Kelly, and the "West Indian" of Cumberland. Goldsmith's "She Stoops to Conquer" has every requisite for making an audience merry. The "School for Scandal," the "Rivals," and the "Critic" of Sheridan are distinguished for epigrammatic witticisms, insight into social weaknesses, and ingeniously contrived whimsical situations; and the first is in many respects superior to any other comedy of modern times. The "Lying Valet" and "Miss in her Teens" of Garrick, the "Belle's Stratagem" of Mrs. Cowley, the "Tom Thumb" of Fielding, the "Man of the World" of Macklin, the "High Life Below Stairs" of Townley, the "Devil to Pay" of Coffey, and especially the score of farcical plays of Foote, were the best and most popular comic productions of this epoch.—The prose authors of the 18th century may nearly all be classed as essayists, philosophers, histo-

rians, divines, and novelists. A new and excellent field for essayists was found in the "Tatler," planned by Richard Steele. Periodical papers containing news had existed in England from the time of the civil war, but this was the first periodical designed to have literary merit and to discuss the features and "smaller morals" of society. It appeared three times a week, extended to 271 numbers from April 12, 1709, to Jan. 2, 1711, and each number contained some lively sketch, anecdote, or humorous discussion, and was sold for a penny. It was succeeded by the "Spectator," which appeared every week-day morning in the shape of a single leaf from March 1, 1711, to December, 1712; after a suspension it reappeared three times a week in 1714, and extended to 635 numbers. The "Guardian" was begun in 1713, but became political, and ceased after the 176th number. Steele was the principal contributor to the "Tatler" and "Guardian," and Addison to the "Spectator," but papers were also furnished by Swift, Pope, Berkeley, Budgell, Tickell, and Hughes. The essays, especially those of Addison, were often models of grace, delicacy, and amenity, and were highly influential in correcting and refining the tone of society. Numerous works similar in form and purpose appeared later in the century, of which the only ones that have retained their place in literature are the "Rambler," written almost wholly by Johnson; the "Adventurer," by Hawkesworth, Johnson, and Warton; the "Idler," chiefly by Johnson; the "World," by Moore, Horace Walpole, Lyttelton, and the earl of Chesterfield; the "Connoisseur," by Colman and Thornton, which received also a few essays from Cowper; and the "Mirror" and the "Lounger," both published in Scotland, and supported by a band of literary lawyers, among whom were Mackenzie, Craig, Cullen, Bannatyne, Hailes, Abercrombie, and Tytler. The letters of Lady Mary Wortley Montagu are models of an easy and elegant epistolary style. The two chief philosophical writers of the early part of the century were Bishop Berkeley and the earl of Shaftesbury, and the "Minute Philosopher" of the former is the happiest imitation in English of the dialogues of Plato. The style of his other metaphysical treatises is singularly animated and imaginative. In his "Theory of Vision" he advanced novel and ingenious views on optics, which are now universally adopted. His doctrine of idealism, the object of which was to prove that nothing exists but God and ideas in the mind, marked an era in English philosophy. The "Characteristics" of the earl of Shaftesbury, once greatly admired for their moral and religious sentiments, and their elegant though affected diction, are now little read. He suggested the theory of a "moral sense," which was adopted and illustrated by subsequent Scottish philosophers. The levity with which he sometimes alluded to Christian doctrines great-

ly impaired his influence. A similar levity is even more apparent in the letters of Lord Bolingbroke, who was long considered a master of written eloquence. A notable work of this period was Warburton's "Divine Legation of Moses" (1738-'41), which, though written to support an absurd theory, is a monument of erudition, and contains passages of great eloquence. The current philosophy of the 18th century was strongly affected by skeptical tendencies, whose influence pervaded the literature of England as of nearly every European country. Bishop Butler, in the preface of his "Analogy," declared that many persons then took it for granted that Christianity was no longer a subject of inquiry, but had at length been discovered to be fictitious. This spirit of skepticism especially pervaded the department of historical composition, which at this time received a great impulse. Unfriendliness toward Christianity is the chief fault of "The Decline and Fall of the Roman Empire," by Edward Gibbon (1737-'94), one of the greatest historical works in the English language, drawn from a wide variety of sources, and written at once with erudition and genius. The history of England by David Hume, and of Scotland and of the reign of Charles V. by William Robertson, have retained their reputation for ease and elegance, though later researches have shown their neglect of accuracy. Less important historical and biographical writers were Echard, Strype, Smollett, Tytler, Ferguson, Middleton, Watson, Lyttelton, Russell, and Jortin. The principal philosophical and critical works after those of Berkeley and Shaftesbury were Hutcheson's "Inquiry into Beauty and Virtue" and "System of Moral Philosophy," Hume's "Essays" and "Treatise on Human Nature," Adam Smith's "Theory of Moral Sentiments," Reid's "Inquiry into the Human Mind" and "Essays on the Intellectual Powers," Beattie's "Dissertations, Moral and Critical," Hartley's "Observations on Man, his Frame, his Duty, and his Expectations," Price's "Review of the Principal Questions and Difficulties in Morals," Ferguson's "History of Civil Society" and "Institutes of Moral Philosophy," Tucker's "Light of Nature Pursued," Priestley's "Matter and Spirit," Lord Kames's "Essays on the Principles of Morality and Natural Religion" and "Elements of Criticism," Hugh Blair's "Rhetorical Lectures," and George Campbell's "Philosophy of Rhetoric." The critical and controversial writings of Bentley and Atterbury belong to the early part of this period. The theological writers of greatest influence were Clarke, Lowth, Hoadley, Leslie, Whiston, Doddridge, Butler, Warburton, Wesley, Lardner, Farmer, and Leland. Johnson, Goldsmith, and Burke surpassed all others as miscellaneous writers, and probably Johnson exerted by his conversation and his pen a greater influence upon the literature and tone of thought of his age than any other individual. His wit and learning first stemmed the tide of infidelity, and turned the literary current in favor of re-

vealed religion. It was said by Burke that he appears far greater in Boswell's pages than in his own, and the reason is that he conversed with admirable simplicity and plainness, but in his writings adopted an elaborately vicious and ponderous style.—In the 18th century the novel assumed nearly the form and character which have since made it a leading department of literature. The "Arcadia" of Sir Philip Sidney had been followed by a large number of chivalrously heroic and courtly pastoral romances, many of them translations and adaptations, as Johnson's once famous "Seven Champions of Christendom," and in the 17th century the "Man in the Moon" of Francis Goodwin. After the restoration the most popular novels of the continent were translated, but of English original fictions, the "Parthenissa" of Lord Orrery and the tales of Mrs. Behn and Mrs. Manley are all that are now remembered even by the antiquary. Daniel Defoe (1661–1731) first gave to English fiction a simple, direct, matter-of-fact, and human interest, and the verisimilitude of "Robinson Crusoe" has never been excelled. The "Tale of a Tub" and "Gulliver's Travels" by Swift, the "History of John Bull" by Arbuthnot, and his "Memoirs of the Extraordinary Life, Works, and Discoveries of Martinus Scriblerus," are satires in the form of fictitious narratives. The writings of Swift are admirable for their vigor and humor. Under his successors the novel became more complex and artistic, embraced greater varieties of character and diversities of treatment, and pictured the artificial refinements and distinctions of society, the contrasts of temper and manners, and the complicated and conflicting relations of life. The "Joseph Andrews," "Tom Jones," and "Amelia" of Fielding, and the "Pamela," "Clarissa Harlowe," and "Sir Charles Grandison" of Richardson, were published near the middle of the century. Fielding claimed for his great work, "Tom Jones," the dignity of a comic epopee. Its plot, which involves wonderfully diversified characters and adventures, is contrived with almost perfect art, and it portrays the especial features of real life in England, with keenness, coarseness, an easy humor, and a buoyant affluence of practical knowledge. Richardson is one of the most powerful, tragic, and tedious of novelists, and his voluminous works obtained almost unexampled popularity in England and on the continent. He and Fielding were embodiments respectively of the idealistic and the realistic tendency, and each entertained great contempt for the writings of the other. The "Peregrine Pickle," "Humphrey Clinker," and other novels of Smollett are distinguished for coarse, comic incidents and broad humor; and the "Tristram Shandy" and "Sentimental Journey" of Sterne contain masterly touches of character, passages and episodes sparkling with wit and fancy, and also much melodramatic pathos and sentimentality. Three works of fiction contributed es-

pecially to refine the public taste and the style of novels; the "Rasselas" of Johnson, a philosophical essay in the garb of an oriental tale, the "Vicar of Wakefield" of Goldsmith, a picture of English rural life remarkable for kindness and taste, and the "Castle of Otranto" of Horace Walpole, a striking Gothic and chivalric romance. In 1771 Mackenzie produced "The Man of Feeling," and a few years later appeared Miss Burney's "Evelina," a picture of life and manners, which showed that both the vulgar and the fashionable life of London might be delineated with lively skill, and with broad comic humor, without a line to offend a delicate taste. This and her second novel, "Cecilia," are especially esteemed for their characterizations.—With the French revolution begins a new period in English literature. Again, as in the age of Elizabeth, great civil and religious changes were agitated; old habits and feelings were to be set aside, old manners to pass into oblivion; and out of the ruins of venerable institutions political theorists were seeking to rear the structure of a new social order. Amid bloodshed and confusion, in the conflict between traditions and hopes, men were forced to speculate on the very elements of human nature and destiny. The commotion of the times marked a change of scene in the drama of European civilization, and though it did not shake the constitution of England, it stirred the mind of the country in every department, and led to deeper moods of thought and to larger sympathies. The revival of poetry had already been prepared by Cowper. A greater influence, probably, was exerted by Robert Burns (1759–'96), whose "Tam o' Shanter," "Hallowe'en," "Cotter's Saturday Night," and numerous songs, were indigenous to the soil of Scotland, and displayed a freshness of humor, pathos, force, and beauty which made them esteemed alike by peasants and scholars, and a union of the morally sublime with the extrinsically humble. Yet his influence did not extend at once to England, where Cowper was still rivalled in popularity by Darwin and Hayley. Connected with these was the Della Cruscan school of affected rhymesters, prominent among whom were Anna Seward, Mrs. Thrale, Mrs. Robinson, Greathead, Merry, Weston, and Parsons, who were ridiculed by Gifford in his "Baviad" and "Mæviad." Matthew Gregory Lewis was the originator of a romantic school, both of poetry and prose fiction, abounding in *diablerie* and all manner of extramundane machinery. His verses were reflected in some of the most powerful contemporary prose, and exerted an influence on the early productions of Scott, Southey, and Coleridge, but were demolished by the "Reviewers" of Canning and Frere, who also ridiculed Darwin's "Loves of the Plants" by a burlesque entitled "The Loves of the Triangles." William Wordsworth (1770–1850), esteemed by many the greatest poet of his century, devoted his life to poetry. It was the solemn business of

his being, the object of all his thought, observation, reading, and experience. His aim was to renovate and refresh literature by bringing back poetry to truth and nature; and he began by composing lyrical ballads on the humblest subjects in language such as was "really used by men." Readers, long familiar with poems on learned themes or marked by polished sentimentalities, marvelled at his bald topics and colloquial platitudes. Yet his simplicity of feeling, truthfulness of delineation, comprehensive spirit of humanity, and union of deep and subtle thought with sensibility, attracted by degrees a circle of enthusiastic admirers. The works of no other poet have been so exclusively the product of personal experience and retrospection. In striking contrast with Wordsworth was Samuel Taylor Coleridge, whose finest pieces, as "Christabel" and "The Ancient Mariner," were produced early in life, and are unsurpassed as strong, wild, and musical sallies of pure imagination. The faultless rhythm of "Christabel," accentual instead of syllabic, was the acknowledged model of Scott's "Lay of the Last Minstrel." As a philosopher and critic he has inspired many followers to rise to higher standpoints than those of Locke, Paley, and Lord Kames. Robert Southey when a schoolboy conceived the design of exhibiting in narrative poems the grandest forms of mythology that ever obtained among men, and his "Thalaba" and "Curse of Kehama," founded on Arab and Hindoo legends, were the partial fulfillments of his plan, and display through a charming diction extensive learning and brilliant imagination. The irregular, unrhyming verse of "Thalaba" he described as the "Arabesque ornament of an Arabian tale." Southey was the most diligent of literary men, and in almost every department of prose and poetry has left monuments of his talent and erudition. A new tendency appeared in the poems of Sir Walter Scott, who combined the refinements of modern poetry with the spirit and materials of border minstrelsy and of the early metrical romances. He adopted in his principal poems the octosyllabic measure, which had been generally used by the old romancers. From 1805 to 1812, when the first cantos of "Childe Harold" appeared, Scott was the most popular British poet; but he retreated to prose fiction as the genius of Byron began to display its strength. John Wilson, after producing a few poems marked especially by delicacy of sentiment and vigor of description, applied himself chiefly to prose literature, criticism, and philosophy. The celebrity of Lord Byron was unrivalled during his brief and impetuous career; and perhaps no other man, dying at 37, ever wrote so much that was remarkable for intellectual power and intensity of passion. A new phase of the poetic mind appeared in John Keats, who gave great promise before his early death not only by his profusion of beautiful and grand conceptions, but also by the progress which he rapidly made in bringing his genius

under the control of judgment. He had an instinct for choice words, which were in themselves pictures or ideas, and he gave an example of refined sensuousness which has affected especially the forms of poetical expression. He was an early admirer of the poetry of Leigh Hunt, whose manner was derived from Italian models, and his influence appears strongly in the productions of Percy Bysshe Shelley, often most ethereal in imagery and language. Though the conceptions of Shelley were derived from imaginative philosophy and from speculations on elemental nature, rather than from human nature and real life, yet he was instinct with a love and intellectual sense of ideal beauty, which appear in single thoughts and images in his larger productions, and especially in some of his lesser poems, as "The Sensitive Plant," "The Skylark," "The Cloud," and the "Hymn to Intellectual Beauty." His "Prometheus Unbound" is worthy of Æschylus. Thomas Moore, a writer of beautiful songs and of light and elegant satires, displayed his highest powers in the four oriental tales of which "Lalla Rookh" is composed, remarkable for their splendor of diction and copiousness of imagery. George Crabbe produced strong impressions by elaborately chronicling a series of minute circumstances, and in brief passages, as in "Sir Eustace Grey," rises to a fine imaginative energy. Samuel Rogers (1763-1855), the contemporary of a long series of poets, followed no one of the new tendencies, but attained high artistic excellence in the heroic couplet, with a nicety of taste and grace of sentiment worthy of Pope and Goldsmith. Thomas Campbell had a higher genius with an equal culture; and in his lyrical pieces he gave to romantic conceptions a classical elaboration and finish which was hardly attempted by his contemporaries. His "Pleasures of Hope" will always rank as an English classic. Charles Lamb, a peculiar and happily wayward genius, wrote almost nothing that is not exquisite, and his few poems, like his essays, reveal an original wit and genial character, moulded by sympathetic study of the old French writers. His reputation rests chiefly on his "Essays of Elia," the finest of their kind in literature. The poems of Thomas Hood, whether serious or comic, are pregnant with matter for thought. Though a singularly clever rhyming punster and jester, his main strength appears in simple pathetic lyrics like "The Song of the Shirt" and "The Bridge of Sighs;" and even through many of his comic pieces, as "The Last Man," "Miss Kilmansegg with her Golden Leg," and others, runs a deep vein of earnest pathos and tragic power. The Scotch poet James Hogg (the Ettrick Shepherd), with a rare imagination, sometimes excelled marvellously in describing things that transcend nature's laws; and his story of "Kilmeny," a child stolen by the fairies and conveyed to fairy land, is a most charming example of pure poetry. The best compositions of Allan Cunningham are ballads and songs of

a national character, as "The Mermaid of Galway," "She's gane to dwell in Heaven," and "My Nannie, O." William Motherwell was successful both in martial pieces, as "The Sword Chant of Thorstein Raudi" and "The Battle Flag of Sigurd," and in plaintive strains, as the ballad of "Jeanie Morrison." Many of the poems of Walter Savage Landor are attempts to reproduce the genius of ancient Greek poetry, and though they have fine and highly intellectual passages, they seem foreign to England and not akin to modern times. His "Gebir" and "Count Julian," however, contain passages excelled by no other poet. He has a surer reputation for his remarkable prose works, the chief of which is a series of "Imaginary Conversations," than which no better English prose has ever been written. Among the minor poets of this period are Henry Kirke White, Grahame, Bowles, Bloomfield, Hamilton, Lloyd, Lovell, Dyer, Cary, Wolfe, who deserves special mention for his short poem on the "Burial of Sir John Moore," Montgomery, Hartley Coleridge, Heber, Keble, Milman, Croly, Moir, James and Horace Smith, Pollok, Procter, Elliott, Clare, Barton, Sterling, Bailey, Bayly, Moxon, Hervey, Milnes, Swain, Mackay, Aird, Bowring, Præd, Tennant, Herbert, Moultrie, Maginn, Anster, Barham, the author of the "Ingoldsby Legends," Trench, A. A. Watts, Aytoun, Tupper, Thomas Davis, Mahoney, Allingham, Barnes, Robert Bulwer Lytton (Owen Meredith), Heraud, Matthew and Edwin Arnold, W. C. Bennett, Alexander Smith, Sydney Dobell, Patmore, De Vere, Horne, Faber, Buchanan, Swinburne, D. G. Rossetti, and Gerald Massey. The most popular English poetess in the first quarter of this century was Mrs. Hemans, among whose numerous productions are some that are melodious in expression and touching in sentiment. The most eminent English poetess of the age, or indeed of any age, was Elizabeth Barrett Browning, who died in 1861. Her longest work, "Aurora Leigh," is a narrative poem, or rather a versified novel, whose characters and incidents illustrate modern English life and manners. A series of love poems called "Sonnetts from the Portuguese" convey perhaps the best impression of her graceful, tender, and yet powerful genius. The dramatist Joanna Baillie wrote also ballads and metrical legends. Caroline Bowles (Mrs. Southey) displayed in many of her slight pieces remarkable elevation and simplicity of feeling. Mary Howitt excels in ballad poetry, and in writings marked by innocent mirth and playful fancy, designed for the young. In contrast with her easy simplicity are the elaborate and impassioned poems of Mrs. Norton, who has been called the Byron of modern poetesses. I. E. Landon checked the diffuseness and efflorescent excess of her early productions, which are distinguished at once for vivacity and melancholy, and gave concentration of thought and style to the verses written not long before her myc-

terious death. Her "Ethel Churchill" gives her a place also among novelists. Other poetesses of the time are Mrs. Blackwood, Lady Flora Hastings, Harriet Drury, Camilla Toulmin (Mrs. Crosland), Mrs. Ogilvy, Frances Browne, Christina Rossetti, Jean Ingelow, Mrs. Mulock-Craik, and Eliza Cook. Miss Adelaide Procter, who died in 1864, wrote many lyric poems of singular beauty and refinement. Of living poets, Tennyson, Browning, and Morris are the most eminent.—The most successful dramatic pieces of this epoch have been those of Joanna Baillie, remarkable for their unity of idea and intellectual completeness, the "Bertram" of Maturin, the happily constructed tragedies of Knowles, the "Lady of Lyons" and "Richelieu" of Edward Bulwer Lytton, the "Julian" and "Rienzi" of Miss Mitford, the "Ion" of Talfourd, the "Fazio" of Milman, the comedies of the younger Colman, the plays of Mrs. Inchbald, the "Road to Ruin" of Thomas Holcroft, the "Honeymoon" of John Tobin, and various plays of O'Keefe, Reynolds, Morton, Poole, Planché, Marston, Jerrold, Buckstone, Brooks, Tom Taylor, Boucicault, Gilbert, Holliday, Robertson, and H. J. Byron. The "Remorse" of Coleridge, the "Bride's Tragedy" of Beddoes, the "Tragedy of Galileo" of Samuel Brown, the "Athelwold" of William Smith, the "Philip van Artevelde" of Henry Taylor, the "Legend of Florence" of Leigh Hunt, and the "Strafford," "Blot in the 'Scutcheon," &c., of Robert Browning, are rather dramatic poems than acting plays.—The novel begins with this century to take a foremost place. In the latter part of the 18th century the circulating libraries abounded with the worthless productions of the so-called Minerva press. The works of Charlotte Smith mark the beginning of the transition from the sentimental to the true in popular fictions. A new energy and dignity was given to them by the political tales of Holcroft and Godwin, and especially by Godwin's "Caleb Williams;" and the romantic fictions of Mrs. Radcliffe, the novels of the sisters Porter, of Dr. John Moore, of Mrs. Inchbald, and the "Monk" of Matthew Gregory Lewis, were at least improvements on frippery love plots. The Arabian tale of "Vathek," by William Beckford, was greatly admired for its imaginative power and literary finish, and the "Canterbury Tales" of Sophia and Harriet Lee are remarkable among English fictions for tenderness and feeling. The delineations of character and society by Miss Edgeworth, Mrs. Opie, and Miss Austen preceded the works of Sir Walter Scott, whose example has given to the novel nearly the same importance in contemporary literature which the drama had in the Elizabethan era. His prodigious familiarity with Scotch characters, anecdotes, traditions, and superstitions, the delight which he took in displays of sense, humor, or sentiment, in every strong and original symptom of character, prove how broad a foundation his fictions had in actual life. The popularity of the

novel in the earlier part of our century was shown by the appearance of a crowd of writers of fiction, among whose works may be mentioned the "Self-Control" and "Discipline" of Mrs. Brunton, the "Cottagers of Glenburnie" of Elizabeth Hamilton, the "Hungarian Brothers" of Anna Maria Porter, the once highly popular "Thaddens of Warsaw" and "Scottish Chiefs" of her sister Jane Porter, the "Cælebs in Search of a Wife" of Hannah More, the "Wild Irish Girl" and the other national tales of Lady Morgan, the "Albigenses," the "Fatal Revenge," and other romantic fictions of Maturin, the "Frankenstein" and "Last Man" of Mrs. Shelley, the "Marriage," "Inheritance," and "Destiny" of Miss Ferrier, the "Annals of the Parish" and "Ayrshire Legatees" of John Galt, the "Salathiel" of George Croly, the "Anastasius" of Hope, the "Valerius" and "Reginald Dalton" of Lockhart, the Scottish tales of Professor Wilson, the eastern romances of Morier and Fraser, the "Sayings and Doings" and other novels of fashion of Theodore Hook, the "Cyril Thornton" of Thomas Hamilton, the Irish stories of Banim, Crofton Croker, Griffin, Carleton, and Mrs. S. C. Hall, the sea stories of Cpts. Marryat and Chamier, the "Tom Cringle's Log" and "Cruise of the Midge" of Michael Scott, the "De Vere" of Ward, containing a portraiture of Canning, the "Headlong Hall" and other humorous novels of Peacock, the "Brambletye House" and "Moneyed Man" of Horace Smith, the "Our Village" of Miss Mitford, the "Victims of Society" and other tales of Lady Blessington, the fashionable novels of Mrs. Gore, the musical novels of Miss Sheppard, the "Deerbrook," the "Hour and the Man," and the politico-economical tales of Miss Martineau, the multitudinous novels of G. P. R. James, and the miscellaneous novels of Ainsworth, Hannay, Borrow, Warren, Lever, and Lover, of Mrs. Trollope, Mrs. Bray, Mrs. Gaskell, Mrs. Marsh, Miss Sinclair, Mrs. Mulock-Craik, Julia Kavanagh, and Lady Bulwer. Since the death of Scott the most eminent and popular of English novelists have been Bulwer, Dickens, Thackeray, Disraeli, Charlotte Brontë, and "George Eliot" (Mrs. Lewes). Of these, Disraeli and Mrs. Lewes are still living. Other living novelists of note are Anthony Trollope, Wilkie Collins, Charles Reade, Charles Kingsley, Thomas Hughes, George MacDonald, Justin McCarthy, B. L. Farjeon, William Black, J. S. Le Fanu, Mortimer Collins, Edmund Yates, Charles Gibbon, Mrs. Florence Marryat Church, Mrs. Oliphant, the baroness Tautphœus, Miss Thackeray, Miss Yonge, Miss Braddon, Miss Amelia Edwards, Mrs. Elizabeth Charles, Miss De La Ramé (Ouida), and Miss Rhoda Broughton.—Within this period Mitford, Gillies, Thirlwall, and Grote have produced elaborate general histories of Greece, Finlay has written on the later and Byzantine period of the Greeks, and St. John on the manners and customs of ancient Greece; Sharon Turner, Godwin, Lin-

gard, Palgrave, Mackintosh, Charles Knight, Lord Mahon, Miss Strickland, and Harriet Martineau have produced works on different periods of English history, and Hallam on the constitutional history of England, and on the history of Europe during the middle ages; and various histories have been written by Southey, Tytler, Coxe, Chalmers, Roscoe, Pinkerton, Dunlop, Mill, Mills, Napier, Milman, Crowe, Elphinstone, and Arnold. Carlyle's "French Revolution," "Oliver Cromwell," and "Frederick the Great" are distinguished for research and vigor of character painting. Alison's "History of Europe from 1789 to 1852" gives the English tory view of events with fullness and vigor. Macaulay's "History of England from the Accession of James II." was early interrupted by its author's death, but holds a very high place in historical literature by its brilliant style, vast research, and liberal tone. Buckle's "History of Civilization," another brilliant work, was also left incomplete by the premature death of its author; it made a strong impression by its novel and ingenious theories and heterodox views. Merivale's "History of the Romans" is a work of great learning, and fills satisfactorily the gap between Arnold and Gibbon. Froude's "History of England from the Fall of Wolsey to the Defeat of the Spanish Armada" is a work of original research and occasionally eloquent style, and throws much new light on the character of Henry VIII. and Elizabeth and of Mary queen of Scots. Gladstone's "Studies on Homer and the Homeric Age" and "Juventus Mundi" are able and scholarly, and have at once a historical, critical, political, and religious character. Rawlinson's "Herodotus" and "Ancient Monarchies" are of high value. Useful manuals of history have been written by Rawlinson, Liddell, and William and Philip Smith. E. A. Freeman's "History of the Norman Conquest" and "Essays" on various points of history are original and suggestive. The recent era excels in narratives of travel, of which the most prominent are those of Mungo Park, Denham, Clapperton, Lander, Campbell, Burckhardt, Belzoni, Alexander, Buckingham, Porter, Clarke, Mure, Forsyth, Eustace, Hobhouse, Holland, Dodwell, Gell, Beckford, Ross, Parry, Franklin, Beechey, Scoresby, Basil Hall, Inglis, Layard, Fellows, St. John, Fraser, Burnes, Barrow, Harris, Head, Burton, Kinglake, Warburton, Stanley, Atkinson, Oliphant, Trollope, Dilke, Dixon, Sala, Wallace, Baker, Speke, Reade, Palgrave, Cooper, Williamson, Alcock, and Livingstone. In scientific works the present century has been especially rich. The chief writers in its earlier half were Herschel, Brewster, Buckland, Davy, Whewell, Nichol, Prichard, John Pye Smith, and Hugh Miller. Among the most prominent of later days are Owen, Murchison, Lyell, Faraday, W. B. Carpenter, Huxley, Darwin, Mivart, Tyndall, Bastian, Gosse, Lubbock, Tylor, McLennan, Lockyer, Proctor, and Grove. In archæology, the

names of Young, Sharpe, Birch, Goodwin, and Wilkinson on Egyptian subjects, of Rich, Layard, Sayce, Hincks, Norris, Rawlinson, and George Smith on Babylonian and Assyrian, have attained distinction. The work of Edward W. Lane on the "Manners and Customs of the Modern Egyptians" is unequalled as a minute and faithful delineation of an oriental people. In the study of Sanskrit and of Indian antiquities the most noted names are Sir William Jones, Colebrooke, Muir, Wheeler, Williams, Cunningham, Fergusson, Caldwell, and Max Müller. The eminent writers on religious subjects were Bishops Horsley, Watson, and Jebb, Joseph Priestley, William Paley, Andrew Fuller, Charles Simeon, Ralph Wardlaw, Thomas Scott, William Wilberforce, Adam Clarke, and Hannah More. The "Tractarian" movement is an interesting department of ecclesiastical literature. Its chief promoters were John Keble, E. B. Pusey, J. H. Newman, and R. H. Froude. Very different phases of belief appeared at about the same time in the writings of Isaac Taylor, Henry Rogers, James Martineau, and William Cureton, while the views of English Roman Catholics were expressed by Cardinal Wiseman, Archbishop Manning, F. W. Faber, and Kenelm Henry Digby. The most remarkable sermons have been those of Alison, Irving, Robert Hall, Chalmers, Robertson, and Spurgeon. The more distinguished writers upon the Bible are Kitto, Trench, Alford, Conybeare, Howson, Ellicott, Colenso, Westcott, Davidson, Henderson, Fairbairn, and J. G. Murphy. Other religious writers of importance are Peter Bayne, Tregelles, R. and C. J. Vaughan, Tulloch, Seeley, Maurice, and Robertson. In biographical works this period is peculiarly rich. The most popular and important of these are the lives of Nelson and Wesley by Southey; of Sheridan and Byron by Moore; of Petrarch and Mrs. Siddons by Campbell; of Burke and Goldsmith by Prior; of Goldsmith, Landor, Dickens, and the statesmen of the commonwealth by Forster; of Napoleon and the English novelists by Scott; of British painters, sculptors, and architects by Allen Cunningham; of the statesmen and men of letters and science of the reign of George III. by Brougham; of the chancellors and chief justices of England by Lord Campbell; of British military commanders by Gleig; of eminent statesmen and great commanders by James; of eminent Scotsmen by Chambers; of Condé by Mahon; of Howard, Blake, Penn, and Bacon by Hepworth Dixon; of Napoleon by Hazlitt; of Sir Walter Scott by Lockhart; of Charles Lamb by Talfourd; of Newton by Sir David Brewster; of Campbell by Beattie; of Mackintosh by his son; of Horner by his brother; of Sydney Smith by his daughter; of Charlotte Brontë by Mrs. Gaskell; of Dr. Arnold by Stanley; of Goethe by Lewes; of Moore by Earl Russell; of Chatterton by Wilson; of Pope by Elwin; of Edward Irving by Mrs. Oliphant; of Sir Joshua Reynolds by

Taylor; of George and Robert Stephenson by Smiles; and lastly we may mention the monographs of John Morley on Burke, Voltaire, and Rousseau, and the autobiographies of Lord Brougham, of Sir Henry Holland, and of Henry Crabb Robinson, and the "Memorials of a Quiet Life" by A. J. C. Hare. Among miscellaneous writers on literature, Isaac Disraeli, Sir Egerton Brydges, and John Foster became prominent near the beginning of the century. The number of books has often been increased by miscellaneous collections from the reviews, journals, and magazines, as the "Noctes Ambrosianæ," from "Blackwood's Magazine," chiefly by Prof. Wilson; the "Essays" of Jeffrey and Sydney Smith, Macaulay and Carlyle, from the "Edinburgh Review;" the witty productions of Douglas Jerrold, collected from "Punch;" and many of the writings of Hazlitt and De Quincey. Cobbett and J. Wilson Croker acquired distinction as political pamphleteers, and the latter also by his vigorous and pungent articles in the "Quarterly Review." Frances Power Cobbe has attained a high reputation by her "Essays" and other writings on a variety of subjects. Among the notable works of the day may be mentioned Morell's "History of Philosophy," Lecky's "History of Morals" and of "Rationalism," Maine's "Ancient Law," the duke of Argyll's "Reign of Law," Greg's "Enigmas of Life," and Baring-Gould's "Myths of the Middle Ages," "Origin and Development of Religious Belief," and "Legends of the Patriarchs and Prophets." Important contributions have been made to English art literature by Lindsay, Eastlake, Leslie, Hazlitt, and especially by Mrs. Jameson, Ruskin, Tyrwhitt, and Hamerton. The principal metaphysical writers of the Scottish school were Thomas Reid, Dugald Stewart, Dr. Thomas Brown, and Sir William Hamilton. The more peculiar tendencies of the English mind appeared in Paley. Bentham wrote important works on jurisprudence; Archbishop Whately on logic, political economy, and theology; J. Stuart Mill on logic, on liberty, and on political economy; and Herbert Spencer has written voluminously on psychology, biology, social statics, and similar subjects.—The best historical and critical works on the literature of England are: Wright's "Biographia Britannica Literaria" (vol. i., the Anglo-Saxon period, 1842; vol. ii., the Anglo-Norman period, 1846); Warton's "History of English Poetry," extending to near the end of Queen Elizabeth's reign (3 vols., 1774-'81); Hallam's "Introduction to the Literature of Europe in the 15th, 16th, and 17th Centuries" (1837-'9, with additional notes in later editions); Collier's "History of English Dramatic Poetry" (1831); Chambers's "Cyclopedia of English Literature" (2 vols., 1843-'4); Lowndes's "Bibliographer's Manual" (new ed. by Bohn, 6 vols., London, 1857-'64); Allibone's "Critical Dictionary of English Literature" (3 vols., Philadelphia, 1858-'73); Craik's "History of

the English Literature and Language" (London, 1861); Morley's "English Writers" (London, 1864-'7) and "First Sketch of English Literature" (1873); Skeat's "Specimens of English Literature from 1394 to 1579" (Oxford, 1871). Among brief manuals are Shaw's "Authors of English Literature" (London, 1848); Spalding's "History of English Literature" (New York, 1853); T. Arnold's "Manual of English Literature" (London, 1869); Day's "Introduction to the Study of English Literature" (New York, 1869); Minto's "Manual of English Prose Literature" (Edinburgh and London, 1872); and Hart's "Manual of English Literature" (Philadelphia, 1872). In 1864 appeared Taine's *Histoire de la littérature anglaise* (5 vols., Paris), exhibiting a comprehensive grasp and keen analysis especially remarkable as the work of a foreigner. It was translated by H. Van Laun and published in Edinburgh and republished in New York in 1871 (2 vols. 8vo).

ENGLAND, John, first Roman Catholic bishop of Charleston, S. C., born in Cork, Ireland, Sept. 23, 1786, died in Charleston, April 11, 1842. He entered the college of Carlow in 1803, and while there founded a female penitentiary and poor-schools for both sexes. He was ordained priest Oct. 9, 1808, and appointed lecturer at the North chapel in Cork, and chaplain of the prisons. In the following May he commenced the publication of a monthly magazine called the "Religious Repertory." In 1812 he became president of the theological college of St. Mary, in which he also lectured on divinity. About the same time he exerted himself to put down bribery at elections, and in the "Repertory" attacked the existing system of criminal jurisprudence, and opposed the purchasing of Catholic emancipation by concessions to the English government. His boldness brought him before the courts, and on one occasion he was fined £500. He founded several religious and charitable institutions in Cork, and in 1817 was made parish priest of Brandon. In 1820 he was appointed bishop of the new diocese of Charleston, S. C., comprising the states of North and South Carolina and Georgia, with a scattered Catholic population of about 8,000, and only four priests, and arrived there in December. Here he established an academy and a theological seminary, in both of which he taught, supporting the latter institution by the revenue from the former. He founded an anti-duelling association, visited every part of his diocese, had special services in the cathedral for the negroes, and established the "Charleston Catholic Miscellany," the first Roman Catholic paper published in America. In 1826 he preached before the senate at Washington. In 1832 he spent some time in Rome, when the pope appointed him apostolic legate to Hayti. He visited that island twice, and made voyages to Europe in 1833, 1836, and 1841. His learning, ability, and high moral character, and above

all his heroism during a season of yellow fever, gave him a high standing in Charleston; and the spectacle was sometimes witnessed of the Catholic bishop preaching on Sunday in a Protestant church to a Protestant congregation. He left many writings, most of which appeared in the periodical press. A complete edition of his works was prepared by Bishop Reynolds (5 vols. 8vo, Baltimore, 1849).

ENGLISH, George Bethune, an American author and adventurer, born in Cambridge, Mass., March 7, 1787, died in Washington, D. C., Sept. 20, 1828. He graduated at Harvard college in 1807, and was admitted to the bar in Boston, but subsequently studied divinity at Cambridge. In 1813 he published "The Grounds of Christianity Examined," a work in favor of Judaism, which was answered by Edward Everett, and by S. Cary. English subsequently edited a western newspaper, and sailed to the Mediterranean as a lieutenant of marines, but resigned his commission, and is said to have professed Mohammedanism. He accepted a commission in the army of Ismail Pasha in 1820, and served as an officer of artillery in an expedition against Sennaar. He afterward became an agent of the American government in the Levant, returned to America in 1827, and took up his residence in Washington. He wrote replies to Mr. Everett and Mr. Cary; a letter to W. E. Channing regarding his two sermons on infidelity (1813); and a "Narrative of the Expedition to Dongola and Sennaar" (London, 1822; Boston, 1823).

ENGLISH, Thomas Dunn, an American author, born in Philadelphia, June 29, 1819. He received the degree of M. D. from the university of Pennsylvania in 1839, and was called to the bar in 1842. He has been connected with journals in New York and elsewhere, edited magazines, and taken part at various times in politics. He is the author of several novels, mostly pseudonymous, and more than 20 successful dramas. Only three of the novels were acknowledged: "Walter Woolfe" (1844), "MDCCCXLIV., or the Power of the S. F.," a political exposé, and "Ambrose Fecit" (1867); and of the dramas only one, "The Mormons," which has been printed and is still occasionally represented. Dr. English is best known by his "Ben Bolt," a popular song, which appeared in the New York "Mirror" in 1842, and his "Gallows-Goers," a rough but vigorous poem, of which hundreds of thousands of copies were circulated during the agitation of the question of capital punishment from 1845 to 1850. He printed a collection of his poems in New York in 1855, but suppressed its publication. In 1856 he established his residence in New Jersey, near New York, where he has since practised as a physician. He has represented his district in the New Jersey legislature. Of late years his literary work has been confined mainly to a series of poems illustrating the revolutionary history

and local dialects of the United States, which have appeared in magazines.

ENGLISH, William Henry. See p. 825.

ENGLISH CHANNEL, an arm of the ocean, separating England from France, extending from Dover to the Land's End, and from Calais to the island of Ushant. At the W. end it is 100 m. wide; on the east, where it is united to the North sea by the strait of Dover, it is 21 m. across, and its greatest width is about 150 m. The English coast of the channel is 390, and the French 570 m. in length. In it are the isle of Wight, Guernsey, Jersey, and other islands. A current appears to run through it from the west. On the English coast it has some excellent harbors, but those on the French side, excepting the artificial port of Cherbourg, are too shallow for men-of-war. Important pilchard, mackerel, and oyster fisheries are prosecuted in its waters. From its shape the French call it *la Manche*, "the sleeve."

ENGRAFTING. See GRAFTING.

ENGRAVING, the art of producing designs, either by incision or by corrosion, on the smooth surface of a wooden block, metallic plate, or other substance, for the purpose of transferring them to paper. In this sense the art is comparatively modern, being but little older than that of printing, but in a more restricted sense it has been practised from a remote antiquity. Engraving on metallic plates is mentioned in Exodus xxviii. 36, and numerous other passages attest that the Israelites were skilful in it, and also in gem and seal engraving. They acquired the art undoubtedly from the Egyptians, who, as well as the Assyrians, engraved both on stone and metal. Specimens of incised copper plates found in mummy cases show that they were executed with tools similar to those now in use, and impressions taken from them at the present day prove that the Egyptians needed but a single step to make the discovery of engraving in its modern sense; but the idea of filling the incisions with color and taking a print from them on paper seems never to have occurred to them. The Assyrians even went so far as to take impressions from their engraved slabs in clay; and wax and other plastic substances were used for a similar purpose. Herodotus, speaking of a period 500 years before Christ, mentions a tablet of brass on which was a map of "every part of the habitable world, the seas, and the rivers." In India and in China the art was practised from the most remote ages. Indeed, the various processes of metallic engraving, die sinking, and gem cutting prevailed among every ancient people who had made any progress in civilization. In its more modern sense, engraving was probably first practised on wood, but its origin is involved in obscurity. The Chinese assert that they printed from engraved wooden blocks more than 1,000 years before Christ; but as they were unacquainted with the art of making paper until about A. D. 100, their assumption may be doubted. It is gen-

erally conceded, however, that they practised the art at an early period, and it is supposed that it was introduced from China into Europe through the intercourse of Venetian merchants. Marco Polo describes the making of paper money in China by stamping it with a seal covered with vermilion. This was about the close of the 13th century, but even this simple art was not practised, so far as is known, in Europe until about a century later. Playing cards and rude cuts for devotional manuals were printed from engraved blocks in Italy, and perhaps in Germany, as early as the year 1400, if not earlier. A decree of the magistracy of Venice, dated Oct. 11, 1441, forbids the importation of any work printed or painted on cloth or paper, because the mystery of making playing cards and printed figures had fallen into decay on account of the influx of foreign manufactures. The "St. Christopher" of 1423, a woodcut of folio size, in the collection of Earl Spencer, was supposed for a long time to be the most ancient example of engraving known; but the baron von Reiffenberg recently discovered one of 1418, and M. Henri Delaborde found two plates printed on the leaves of an old manuscript which prove the existence of wood engraving and the use of the printing press in 1406 (*Gazette des Beaux-Arts*, March, 1869). Among the earliest specimens of illustrated books that have come down to us is the so-called *Biblia Pauperum*, supposed to have been produced between 1430 and 1450. It is a small folio of 40 leaves, each containing a picture, with a text of Scripture or other explanatory sentence below it. The *Speculum Humanae Salvationis*, another noted example of block-book printing, dating from about 1470, consists of 63 leaves of the same folio size, containing 58 pictures, with two lines of Latin rhyme under each. The legends on these early pictures led to the invention of printing. Many works printed in Italy, Germany, and England during the latter part of the 15th century were adorned with cuts, but they were generally of the rudest kind, with broad heavy lines. Near the beginning of the 16th century "cross hatching," as the lines of shadow crossing each other are technically called, was first practised. It was freely used in the Nuremberg chronicle in 1493. The art made rapid progress, and early in the 16th century reached a high degree of excellence. The engravers invented about this time a way of joining the blocks together so that plates of very large size were made. One representing the triumphal arch in honor of the emperor Maximilian I. measured 10 by 9 ft. About 1610 wood engraving began to decline, and at length was applied only to tapestry and calico printing. The art was revived in recent times, the chief impulse being given to it by the founding in England of the "Penny Magazine" about 1833. This work was to contain many illustrations, and to be published cheaply and at short intervals, which made it necessary to print the pictures with the letterpress. This

could be done with wood engravings only, and great pains were taken to make improvements in the art. Since then it has made rapid advances, and has resumed the place in book illustration from which plate engraving for a time deposed it.—German scholars long regarded Martin Schön or Schongauer as the inventor of plate engraving, quoting some impressions executed, according to them, about 1460; but the abbé Zani found in Paris a proof of a pax representing the coronation of the Virgin, dated 1452, the original plate of which, by Maso Finiguerra, is still preserved in Florence. This would seem to corroborate Vasari's assertion that the first use of a metal plate for engraving was by Finiguerra, a goldsmith of Florence, who practised the decoration of gold and silver plate with *niello* work, a process consisting of running into lines cut in the metal a black alloy of silver, lead, copper, sulphur, and borax. The surface, when scraped down and polished, appeared beautifully ornamented according to the skill and taste exhibited in the pattern. To obtain a copy of the engraved figure before filling it, Finiguerra is said to have applied soot and oil and taken an impression on damp paper; and thus was made the first print on paper from a metallic plate. But Passavant, in the *Archives de Naumann* (1858, p. 1), describes an engraving of the Virgin bearing the date of 1451; and Renouvier in a recent pamphlet reveals the existence of a series of prints of the "Passion" made in 1446. The earliest works were executed on tin, zinc, or iron; but copper soon became recognized as the metal best adapted for engraving, and until the invention of steel engraving it was used almost to the exclusion of other metals. The art spread quickly over Europe. Painters of distinction, as Botticelli, Andrea Mantegna, Giovanni Bellini, Campagnola, and others, gave their attention to it, and it was rapidly perfected. This was especially the case in Germany and the Netherlands, where it was adopted by many eminent men, among whom Albert Dürer is particularly distinguished. Rembrandt, Vandyke, and other great painters also executed valuable works with the etching needle, and Raphael highly prized the services of the great Italian engraver Marc Antonio, who transferred to copper many of his designs. The art was introduced into England at an early period, an illustrated work called the "Golden Legend" having appeared in 1483, and in 1543 Vesalius's work on anatomy, in Latin, illustrated with copperplate engravings. Maps of English counties were engraved in 1579, but little progress was made previous to the 18th century, when Vertue and Hogarth, and subsequently Strange, Woollett, Bartolozzi, Sharp, and others, brought the art to a high degree of excellence. Italy is no longer preëminent for her engravers; but within the century she has furnished some of transcendent merit, whose works will compare with the best of their predecessors. At the head of these stands Raphael Morghen (died 1833),

whose "Last Supper" after Da Vinci, and "Transfiguration" and *Madonna della Seggiola* after Raphael, are among the most costly productions of the art. Schiavoni, the Anderlonis, Bettelini, Longhi, Porporati, Pavon (a pupil of Raphael Morghen), and others, have engraved with success many of the works of the old masters. Toschi (died 1854) took high rank among line engravers by his print of the "Entry of Henry IV. into Paris," after the picture by Gérard, as well as by his "Descent from the Cross," after Volterra, *Spasimo di Sicilia*, after Raphael, and other works from the old masters. Rosaspina, Bisi, Mercuri, and others, have produced many meritorious prints from masters both old and modern. In Germany the art has witnessed a steady improvement since the beginning of the century. Rahl, Hess, Reindel, Umer, Leybold, Kessler, Kobell, Barth, Klein, J. H. and J. J. Lips, Steinla, and others, have gained eminence as line engravers; and Christian Friedrich von Müller, who died in 1816, aged 33, produced a print from Raphael's *Madonna di San Sisto*, which is regarded as one of the noblest achievements of the graver. His father, J. G. von Müller, was also a good engraver, and among other works executed the well known print of the battle of Bunker Hill from Trumbull's picture. The *renaissance* in German painting, effected by the efforts of Cornelius, Overbeck, Schadow, Kaulbach, and others, has had a marked influence on the art of engraving, and within the last half century has arisen a school of engravers who have coöperated with these masters in their endeavors to restore to art its ancient simplicity and deep religious feeling. Prominent among these are Ruscheweyh, who was associated at Rome with Cornelius and Overbeck, and who has engraved the chief works of the new school; Amsler, Keller, the Felsings, and Merz, who have drawn their inspiration from the same source; Thäter, Eichens, Mandel, Rahn, and Schleich, who, among other works, have engraved some of the masterpieces of Kaulbach, Schnorr, Scheffer, &c. In France as in Germany the efforts of engravers are now less directed to the reproduction of the works of the old masters, or of indifferent designs for illustrated books, than to the execution of prints after contemporaneous painters. David, Gros, Ingres, and others, have afforded numerous subjects; and of such popular painters as Vernet, Delaroche, and Ary Scheffer, nearly every important work has been engraved. Yet France has produced some excellent line engravers after the old masters, among whom may be mentioned the baron Desnoyers (died 1857), who executed fine prints of Raphael's *Belle jardinière* and "Transfiguration," and of Gérard's Napoleon; Prévost (died 1861), who engraved Paul Veronese's "Marriage of Cana;" the Massards, Lecomte, Loriehon, Bein, Richomme, Forster, Martinet, Lignon, Gudín, Audouin, Bridoux, Girard, &c. Of those who have

devoted themselves to the works of modern masters, the most eminent perhaps is Henriquel-Dupont, whose line engraving of Delaroché's fresco in the hemicycle of the *palais des beaux-arts* is unsurpassed in merit or dimensions by any recent work of the kind. Blanchard, Prudhomme, Louis, and the brothers François, have engraved many of the works of Vernet, Delaroché, and Scheffer, and C. R. J. François has confined himself exclusively to Delaroché's works. Girardet (died 1865) engraved from these masters, and also several subjects from American history, including Leutze's "Washington Crossing the Delaware," Stuart's portrait of Washington, &c. Jazet is celebrated for his aquatints from the battle pieces of Gros and Vernet, and Calamatta (died 1869) executed admirable portrait prints of Lamennais, Guizot, Fourier, and Madame Dudevant. Calame, a Swiss artist (died 1864), produced many admirable etchings. The practice of copying the old masters, and to a considerable extent of line engraving, has fallen into disuse in England, the latter being employed principally in large landscapes or in the higher class of figure pieces. Here again, as in Germany and France, the works of a few eminent native artists have occupied the attention of the chief engravers almost exclusively, and under the influence of painters like Reynolds, Lawrence, Wilkie, Turner, and Landseer, the art has been prosecuted with great success. Raimbach, Stewart, Burnet, Smith, and others, have made Wilkie's pictures generally known through the medium of excellent line engravings; and Goodall, Willmore, Pye, Wilson, Prior, Finden, Wallis, and Consen have done the same for the landscapes of Turner, Stanfield, Constable, Callcott, Roberts, and the other great English masters of this department of painting. Martin's mezzotints of the "Fall of Babylon," "Belshazzar's Feast," &c., after his own designs, are striking works and well known. The engraving of Sir Edwin Landseer's works, of which nearly 200 different prints have appeared, has employed a numerous band of engravers, prominent among whom are the artist's brother Thomas Landseer, Cousins, Lucas, Bromley, Ryall, Atkinson, Baker, Wass, Gibbon, Graves, Bacon, and Robinson. Doo, Watt, Heath, Hollaway, who engraved the cartoons of Raphael in Hampton court, and others, have produced good line engravings from the old masters; and the more modern English painters, such as Leslie, Newton, Eastlake, Etty, Ward, Webster, MacIse, Millais, Frank Stone, Herring, and T. Faed, have found ready interpreters in Richardson, Bellin, Sadd, Howison, Walker, Simmons, Stocks, Reynolds, J. Faed, Hall, and many others. The etchings of George Cruikshank from his own designs are also of the highest order of merit. Wood engraving in Europe, and particularly in England, has reached a perfection unknown to any previous era in the history of art; and in the

latter country the woodcuts of the Dalziel brothers, Evans, Cooper, Palmer, Linton, and others, have a richness and delicacy of finish not inferior to the highest efforts of the engravers on metal. In the Netherlands the principal engravers are Vinkeles and Van Genus, Van Trostwyck, Van Os, Overbeck, Janson, Chalon, Claessens, De Frey, and Corr. In the United States the most eminent names are Durand, Cheney, Smillie, Danforth, Dick, Halpin, Marshall, and Andrews.—According to the material used for receiving the designs, the art is designated as xylography, chalcography, siderography, and lithography—from *ξύλον*, wood, *χαλκός*, copper, *σίδηρος*, steel, and *λίθος*, stone. The last will be treated under its own designation. Engraving proper may be considered under two heads: wood engraving, where the print is made from a surface, and plate engraving, where the impression is made from lines cut into the metal or other substance on which the engraving is made. I. XYLOGRAPHY, or WOOD ENGRAVING, is the earliest, simplest, and cheapest form. Various woods are used, boxwood exclusively for fine work, and mahogany, maple, and pine, and occasionally pear, apple, and beech, for coarse work. The old engravers cut on large blocks of soft wood, such as pear tree, the way of the grain; those of the present day use small blocks of hard wood, and cut across the grain. Some soft woods, such as pine, used for engraving placards and posters, are still cut with the grain. In preparing boxwood blocks, the log is sawn into transverse slices, "type high" (about $\frac{1}{16}$ of an inch), so that the face of the engraving will be even with the type when in the form. After thorough drying, to prevent warping and cracking, it is trimmed square. If the cut is large, a number of these blocks are put into the hands of different engravers, each of whom executes a part, and the various pieces are then fitted together and securely clamped. In this manner a very large engraving can be produced in a short time. The face of the block having been made smooth and free from inequalities, the artist covers it with a light coat of flake white mixed with gum water. This makes a ground for the drawing, and retains pencil marks or India ink. Drawings may be made with a lead pencil, pen, brush, or with brush and lead pencil combined. The drawings of the time of Albert Dürer are supposed to have been made with pen and ink. Modern drawings, not being fixed, are liable to be obliterated by the engraver, and are usually covered with paper, a small piece being torn away from the part on which he is engaged. Drawings made with the lead pencil and the pen require more mechanical than artistic skill in the engraver; those with the brush, or brush and pencil combined, the reverse. The work of the wood engraver is precisely the opposite of that of the plate engraver. The latter cuts the lines of the drawing into the metal; the former cuts

away the surface around the lines, leaving them in relief. There is a method of wood engraving in which the lines are cut in the block as in plate engraving. It differs from the latter in that the ground receives the ink instead of the lines, which thus appear white on the paper.

FIG. 1.—Tools for Wood Engraving. 1. Elliptic. 2. Gouge. 3. Chisel. 4. Tint. 5. Lozenge. 6. Graver. 7. Tool for Pine. 8. Tool in Handle.

Modern engravers use a greater variety of tools than were known in the early stages of the art. The old engravers had only small knives and gouges; now the artist has gravers of different widths to cut out the spaces between fine lines, and broader chisels and gouges to remove wide spaces. Fig. 1 shows the different tools used. Parallel lines, used largely in wood engraving where a flat even appearance is desired, are made by the ruling machine, which produces effects in relief printing similar to those of the ruling machine in plate engraving. (See fig. 2.)

II. PLATE ENGRAVING. Engraving on metal plates may be classed under the following heads: etching, line, stipple or chalk, mezzo-

tint, and aquatint. The instruments used are the same, with some modifications, in all the styles. The etching needle or point is a piece of stout steel wire inserted in a handle and ground to a fine point on a hone. Two or three needles, of different thicknesses, are used,

some for broad and some for fine lines. The dry point is a similar instrument, but with a more delicate point, used for making outlines to be filled up afterward by the burin or graver. The latter, the principal tool of the engraver, is a small instrument of tempered

steel, with one end ground off obliquely so as to produce a sharp cutting point, and the other inserted in a handle. Several are required, the ends of which differ in form from a lozenge to a square, the former for cutting fine, the latter broad lines. The angle at the meeting of the two lower sides is called the belly, and the breadth of the end the face. The scraper is an instrument used for taking off the burr raised on the metal by the cutting tools. The burnisher is employed to soften lines bitten in or engraved too deep, or to polish the plate when scratched. —Etching may be classed under two heads, painters' etching and engravers' etching. The former is a method of engraving which was practised by many of the old painters, and which has recently come into fashion again among artists. The process is nearly the same in both cases. In painters' etching a copper plate is used, which is covered with a film composed of asphaltum and wax, technically called the etching ground. This ground is blackened with lampblack mixed with the varnish. The engraver then makes his drawing with etching needles, cutting through the ground to the plate, making his lines fine or broad according to the depth required, working as he would with a pen or pencil. A border or bank of wax is then raised around the plate, and diluted nitric acid is poured over it. The etching ground resists the action of the acid, which corrodes only the parts uncovered by the needles. When the work is well bitten in, which will be in about a quarter of an hour, the acid is poured off and the plate cleaned, when a proof is taken. If the lines of the lighter parts appear to be sufficiently etched, they are painted over with some of the asphaltum ground dissolved in spirits of turpentine or with sealing wax dissolved in alcohol, and the acid is reapplied to the other parts. This covering of a portion of the plate is called stopping out, and the process of stopping out and biting in is continued until the required depths of line are all attained. Three bitings in are generally enough for a painter's etching. Lines too strongly bitten are rubbed up with the burnisher. Various modifications of this process have been used. Other pro-

cesses also are in use, for which certain advantages are claimed. That invented by P. G. Hamerton in 1871, and named by him the "positive process," is much practised. The plate is brightened first with cyanide of silver, on which is laid a ground of white wax dissolved in ether, the effect of the ether being to purify the wax. After drying for three days, a second coat of wax is applied, and the back and edges of the plate are painted with Japan varnish. When ready for use, the plate is placed in a shallow bath, into which it is fastened by balls of wax pressed into the corners. The mordant, composed of chlorate of potash 20 grammes, hydrochloric acid 100, and water 880, is then poured over the plate so as to cover it completely, when it is ready for the artist, who sketches with the usual needles or with strong sewing needles fastened in a handle. If the bath is in proper condition, the line will blacken as soon as it is drawn. If a second or a third biting in becomes necessary, the plate must be cleaned, resilvered, and coated with fresh wax. The advantages of the positive process are that the artist sees his work in black on a white ground, as in drawing with a pencil on paper, and the lines never glisten as in the old method. The invention of etching is generally attributed to Albert Dürer, but it is probable that it was practised before his time. Rembrandt is the representative etcher, and some of his works command very high prices. One known as the hundred-guilder print has been sold for £1,180. Rembrandt founded the Dutch school. Among his followers, Ostade produced some fine works, and the etchings of Bega, though wanting in delicacy, are prized for the spirit and life of the figures. The landscapes and cattle pieces of Nicholas Berghem and the animals of Paul Potter are celebrated. Vandyke's etchings are as noted as his paintings. Of the French school, Jacques Callot, Charles Méryon, Lalanne, Jules Jacquemart, Charles François Daubigny, Appian, and Jongkind have produced remarkable works. Among English etchers of note are Turner, David Roberts, Wilkie, Geddes, Ruskin, Landseer, Cruikshank, Doyle, Whistler, Samuel Palmer, and Hamerton. Germany is not particularly noted for etchers, and in Italy Canaletti alone is prominent. A number of American artists have practised etching within the past few years, but they have confined themselves generally to humorous subjects. The best treatises on the subject are that by Lalanne (Paris, 1865), and P. G. Hamerton's "Etchers and Etching" (London, 1868). Etching is employed largely for producing ornamental designs on glass. The method is the same as in etching on copper, but the acid used is hydrofluoric, generated in a leaden vessel over which the prepared glass is placed.—Engravers' etching is engraving executed with the tracing point instead of the burin, and bitten in with acid. A portion of every composite steel engraving is etched.

An engraver's etching differs from a painter's in that it is unfinished, the work being only initiatory to that of the burin. Engravers of historical and other subjects, including figures, etch little more than the outlines and the broad masses of the draperies; but landscapes, skies, architectural work, and animals are generally produced in this way. In map engraving, the sinuous lines indicating coasts and the banks of rivers, the marks denoting swamps, and the outlines of mountains are etched. Roads, canals, the waters of lakes and rivers, groups of houses, &c., are put in with the burin. Lines which can be ruled are made with the dry point, and cities, towns, and villages, represented by various kinds of circles, are engraved with an instrument peculiar to map makers.—Line engraving is the art of rendering or translating forms, materials, and colors or effects of a picture into black and white through the medium of lines engraved or sunken in the surface of metal plates or other materials, from which impressions may be printed. Forms are rendered by the directions and courses of the lines, effects and color by the depth and width of the lines and their distances from each other, and materials or surfaces by the quality of the lines. The highest grade of line engraving is executed with the burin or graver directly on the metal, and is limited to reproductions of the human figure. Delicate lines are put in with the dry point. This does not cut clean, like the burin, but leaves a burr which is removed with the scraper. Parallel lines required in series, such as those in flat tints in skies or in buildings, are cut with the ruling machine, which produces more even tints than hand work, but at the expense of freedom. The lines too, unless very skillfully ruled, wear quicker and become clogged with ink sooner than those made with the graver.—Stipple engraving is executed in dots instead of lines, and is practised commonly in connection with etching. The plate is covered with the etching ground, and the subject is transferred to it in the usual way. The outline is then laid in with small dots with the graver, and the darker parts are etched in larger dots laid closely together. The ground is next removed and the work finished with the graver. For producing great delicacy in shading, a fine dry point is used. Stipple engraving was much practised by the English in the latter part of the last century. It is combined frequently with line engraving on the same plate. It is well adapted to give a soft pleasing effect in shading the human figure, and is employed therefore in portraiture and in engravings of sculpture. It is sometimes called chalk engraving, because used to imitate drawings in chalk. In this case the dots are made with less regularity and uniformity in size. Sometimes the dots are struck in with a hammer, when the work is called *opus mallei*, but this is little practised. Stipple engraving dates from the end of the 17th century, and

Morin and Boulanger are considered as the inventors. In 1740 François invented an instrument called a roulette, a small steel wheel with a toothed edge, which being rolled over the plate produced dotted lines. This was used chiefly in chalk engraving.—Mezzotint engraving differs from other styles both in execution and in the appearance of the impressions given by the plate. A mezzotint engraving resembles a drawing washed in with the brush, rather than a work executed with a steel instrument. The operation is the opposite of that in other methods. In ordinary engraving the process is from light to dark, in mezzotint from dark to light. The plate is prepared by running over it a toothed instrument called a cradle, which raises a burr all over its surface. This is called laying the ground. A print taken from the plate at this stage would be uniformly black, while an ordinary plate previous to engraving would give no impression. The plate being thus prepared, the lights and shades of the engraving are produced by rubbing away with scrapers and burnishers the parts where lights are desired, and by increasing the indentations for deeper shades. An agreeable softness is produced by the harmonious gradations of the tints more easily than by other methods. By etching the outlines before laying the ground, a more decided character is given to the print. A pure mezzotint engraving is seldom produced, the process being combined usually with line and stipple. Mezzotint plates are now prepared by a machine invented by Saulnier for ruling lines. This style of engraving is supposed to owe its origin to Ludwig von Siegen, an officer in the army of the landgrave of Hesse, whose first work was published about 1640. It was introduced into England by Prince Rupert, and several prints executed by him are still in existence.—Aquatint engraving is so called from the similarity of its effect to a drawing in India ink or bistre. After the design has been etched in outline, and the etching ground removed, a solution of resin or of Burgundy pitch in alcohol is poured over the plate as it lies in an inclined position. As the alcohol evaporates, the resinous matter is left in granulations over the surface. The design is then drawn with a gummy sirup called the bursting ground, which is applied wherever a shade is to be produced. The lights are left untouched. The whole is next covered with a coating of turpentine varnish, and a border of wax is raised around the plate. Water is poured upon it and left for 15 minutes, when the bursting ground cracks open, exposing the copper. It is then ready for the nitric acid, which is used as in etching, and may be applied several times after each stopping out of the portions sufficiently corroded to produce the desired shades. The bursting ground is not always required, the acid being applied directly upon the granulations, which protect the parts they cover, and the varying shades are produced

by repeated corrosions and as many stoppings out. Some artists dust certain resinous powders on the plate instead of obtaining the granulations by the alcoholic solution. Gum sandarac is used for this purpose, or the purest resin pulverized, and sifted through muslin upon the plate, to which the particles attach themselves on its being heated. Colors are sometimes applied to the plates, and the design is at once printed in its intended colors; but where several colors are employed in contact with each other, it has been customary to use as many different plates, one for each color, and print in succession, the plates being kept in their exact places by fitting upon four fixed pins that pass through holes in their corners. This method was formerly practised in printing cotton cloth. Aquatint has been superseded by lithography and chromo-lithography, and is now but little used. The process is a French invention, and originated with J. B. Leprince about 1787. It was perfected by English artists, who executed works of great merit by this method.—Copper was used almost entirely for plate engraving until the present century, when the discovery by Jacob Perkins, of Newburyport, Mass., of a process for decarbonizing steel made steel-plate engraving possible. The metal had been employed once in England in 1805, in the engraving of the ceiling of the star chamber in Smith's "Topographical Illustrations of Westminster;" but its hardness prevented its general use. Since Perkins's invention steel plates have gradually supplanted copper, and now no artist who understands the relative capabilities of the two metals uses the latter for fine engraving. Another invention of Perkins's, the transferring process, effected a still greater revolution in the art, more especially in the production of small engravings, such as vignettes and other cuts for bank notes. Its advantage is that the plate, after being engraved in the usual manner, can be used to transfer the design to other plates, so that an indefinite number may be produced from the original. The softened plate when finished is reconverted into steel, and a decarbonized cylinder large enough to receive the impression is then rolled over it by means of a powerful machine until the engraved impression appears on it in relief. The cylinder is then hardened, after which it can be used for returning the impression to softened plates, each of which will be an exact counterpart of the engraved plate. The original thus serves to give but one impression to the transfer roller, which in turn is used to make any number of plates. The most important application of this process is for engraving bank notes, which branch of the art is treated below. The plates of notes are transferred usually in parts, a single vignette or figure at a time. In some cases the entire plate has been put on the roller, but to do this successfully requires the utmost care on account of the spreading of the softened steel under pressure.—*Bank-note En-*

graving. The art of engraving owes some of its most important developments to the efforts of artists and mechanics in manufacturing bank notes. In the United States this business has nearly attained perfection, and whatever skill has been shown in Europe in bank-note engraving has been the result of improvements introduced from this country. The rude, cheap notes issued by the bank of England a century and a half ago were reproduced for nearly a hundred years, when frequent forgeries rendered a change necessary. In the year 1800 the directors first endeavored to furnish notes which should be secure from counterfeits, but forgeries multiplied, and it was not till 1820 that any remarkable improvement was made in the style of engraving them. In the United States a superior system had existed for some years. The continental notes, the first of which were issued in 1775, were engraved on copper by Paul Revere of Boston. They were of no importance as works of art, and the notes engraved afterward for the bank of North America were little better; but the invention of the transferring process by Perkins raised bank-note engraving to the rank of a special art. Perkins acquired so great a reputation as a manufacturer of bank-note plates that in 1808 a special law was passed in Massachusetts directing the use of a peculiar style of note with a "stereotype check," invented by him, by all the banks of the commonwealth. This, though a sufficient protection against counterfeiting at the time, grew so familiar in 20 years that fraudulent imitations became numerous, and the law was finally repealed. About 1814 Perkins associated himself in Philadelphia with the firm of Murray, Draper, and Fairman, with whom he remained several years, still experimenting with his machinery. While he was there Asa Spencer, who was connected with the same firm, invented a method of applying lathe work to bank-note engraving. This adaptation of the geometric lathe, although but a new application of an old principle, was made so successfully that Spencer received as high credit as if he had been the original inventor. To Mosley I. Danforth also, a native of Hartford, Conn., who spent 12 years in the study of his art in London and Paris, is due much credit for the rapid advancement of bank-note engraving in this country. He associated himself with Murray, Draper, and Fairman, and compelled rival engravers to adopt a higher standard by the exquisite style and finish of his work. In 1818 Mr. Perkins, attracted by the liberal propositions for competition offered by the bank of England, went to London, accompanied by Mr. Fairman and a number of experienced workmen. The superiority of his work was immediately perceived, but not so readily acknowledged; and unfortunately for his prospects, a London wood engraver, Mr. Darton, succeeded after many efforts in making a woodcut copy of one of his pieces of lathe work, a circumstance which was so strongly

urged as an argument against the American competitor that he was obliged to withdraw from the contest, and the privilege of manufacturing the notes was awarded by the bank to Messrs. Applegarth and Cowper in 1820. But so confident was Mr. Perkins in the security of his notes, that when supplying a bank in Ireland he voluntarily agreed, if they should be forged, to furnish a new issue without charge. Perkins remained in London, where he established a partnership with Mr. Heath, an eminent engraver, which lasted during his life. His improvements were adopted in England and in some parts of the continent; but bank-note engraving has been much less developed in Europe than in the United States. In the bank of England security against counterfeiting is sought by the use of a peculiar kind of paper rather than by fine engraving. The notes are printed from an electrotype surface, a method fatal to delicacy of work, although possessing the advantages of speed and cheapness. By this system, introduced by Mr. Smee in 1854, the engravings are used as moulds from which electro-casts are taken, and the notes are printed from these upon steam presses. The paper is made by hand in moulds which are just large enough to form a sheet for two notes. After printing, these notes are separated by an irregular cut, so that each has a selvage on three sides and on the fourth an indented edge. The notes of the bank of France are printed also from a surface, but they are neater in engraving and more elegant in execution than those of the bank of England. The artistic perfection which characterizes bank-note engraving in the United States is the result of a public necessity growing out of our banking system. Under the old local system the issues were so numerous that familiarity with the different notes became impossible; and as the laws furnished no sufficient protection against counterfeiting, other means had to be adopted for security. This was attained in the superior execution of the notes themselves, and by the combination of the highest artistic excellence with mechanical skill, perfect counterfeiting is rendered almost impossible. The business of bank-note engraving is carried on in the United States by three companies, the "American," incorporated in 1858, the "National," in 1859, and the "Continental," in 1862, all of which are in the city of New York. A large part of the bank notes, bonds, and postage and revenue stamps used by many of the principal nations of the world are made by these corporations. Among the foreign nations for which work has been done are Russia, Sweden, Italy, Greece, Spain, Switzerland, the British North American provinces, Cuba and other West India islands, United States of Colombia, Venezuela, Ecuador, Mexico, the states of Central America, Brazil, Peru, Bolivia, Chili, Argentine Republic, Paraguay, Uruguay, Japan, and the Hawaiian islands. The national currency and legal-tender notes

of the United States, the national bonds, and the revenue and postage stamps, are all made in whole or in part by them. To insure greater security, most of the currency is engraved and printed in three establishments, the same notes passing through two of the companies here and then going to Washington, where they are finished.—The American bank-note engraver confines himself to line engraving on steel; stipple, mezzotint, aquatint, and other methods not being suitable for his purposes. In order to attain the greater security against imitation, the engravings are made elaborately fine, from drawings by the best artists, and the plates are decorated with geometric designs cut by machinery with an exquisite minuteness and regularity impossible to be accomplished by hand. Prominent among American designers of vignettes are the names of A. B. Durand, J. W. Casilear, James D. Smillie, F. O. C. Darley, and James Maedonough. The drawing of a vignette is made much larger than the intended engraving, and it is finished with the most elaborate attention to detail. This design is then reduced, by copying on a daguerreotype plate, to the size required for the bank note. It passes now into the hands of the engraver, who traces with a steel point on the daguerreotype plate the outlines of the picture. An impression is then taken on paper from this plate, and while the ink is still fresh the outline engraving thus obtained is laid face downward on a softened steel plate and passed through the press. The exact outline is thus transferred to this plate, which is then treated like any other line engraving. After the engraver's work is done the plate is hardened by restoring its carbon. This plate is never printed from directly, but is retained as a die, to be reproduced by the Perkins process. The cost of engraving an ordinary vignette is from \$300 to \$400, but large and elaborate ones are more expensive. The time required is from one to two months. The principal vignette engravers in the United States now are James Smillie, Charles Burt, Alfred Jones, W. W. Rice, F. Gursch, S. A. Schoff, Louis Del Noce, and James Bannister. There are usually from two to three vignettes on the face of a bank note, each of which is engraved originally on a separate plate. The machine work, technically called "counters," on which the denominational numbers are engraved, as well as the other lathe ornamentation, is done also on separate plates, which are hardened for dies. A bank-note company always has on hand a large number of these dies of vignettes and other designs, and new ones are continually produced. The designs made by the various machines in use cannot be imitated excepting by similar machines, and these cannot easily be procured by counterfeiters. The lathe invented by Spencer has been perfected to a degree undreamed of by him. A first-class lathe costs about \$5,000. Many of its parts are as nicely constructed as the works of a watch. It

moves with the most accurate minuteness, and can be adjusted to engrave figures of almost microscopic delicacy of detail. In making new designs the operator experiments on smoked glass, which being held to the light shows the pattern produced. If satisfactory it is reproduced on soft steel, to be afterward hardened into a die. Parallel lines are engraved by the plain ruling machine, which works also with mathematical accuracy. By the medallion ruling machine any coin or medal, or any figure, whether cameo or intaglio, may be reproduced on a plane surface. This machine is not used now, as cheaper ones that will do similar work are made in Germany. The cycloidal machine invented by Cyrus Durand, now also in disuse, is capable of doing very fine work. A machine called the "geometrical pantograph," patented in this country in 1866, is the invention of Edmund Oldham, formerly an engraver in the bank of Ireland, but now of New York. It is remarkable for its capabilities, being able to reproduce any design either of the same size as the original, larger, or smaller. Like the medallion ruling machine, it is guided by the hand. After the lathe-work patterns have been cut on the soft steel, a part of the centre of the counter large enough for the denominational figures is smoothed by erasing the design. As this portion is then a little lower than the surrounding surface, it is forced up by blows of a hammer on the back, and the figures are engraved on it by hand. The distinctive name of the bank and other large letters are also engraved by hand. In designing a new bank note, impressions from various vignettes and counters are made on paper, and the pieces are fitted together by the modeller in such a manner as to leave appropriate spaces for the lettering and signatures. When a satisfactory design is secured, the next process is to transfer the several plates which make up the note to the plate from which the notes are to be printed. The latter is large enough usually to contain four notes, each of which is produced on it by successive rollings under the cylinders. This large plate is not hardened like the original, but is printed from in its soft state, and is capable of producing about 60,000 impressions before becoming impaired by wearing.—The printing of bank notes demands extreme care at every step. The ink must be nicely ground and mixed, and of the finest quality. Formerly the best black ink was made from Frankfort black, a charcoal obtained from grape and vine lees, peach kernels, and bone shavings; but now it is usually prepared by calcining sugar in an air-tight iron vessel. If the notes were printed in black alone, they could easily be reproduced by photography. To guard against this, many devices have been employed. At one time several colors were used, but it was found that all the tints could be removed chemically from the paper without destroying its texture. At last

a green ink was invented, made from the anhydrous sesquioxide of chromium, which filled the required conditions; it could not be removed without destroying the black ink with it. This practically prevents counterfeiting by photography, for green acts the same as black on the photographic plate. This green ink was used for several years in printing the United States money, but it was finally discarded because it wore down the plates so fast that it increased largely the cost of producing the notes. When different colors are used, separate plates are required for each tint, only one of which is printed at a time. A good workman can make from 500 to 600 impressions in a day, whereas by the electrotype process of the bank of England 3,000 can be produced in an hour. After printing, the notes are dried by artificial heat in the drying room. This process, which formerly required a week, is now accomplished in a few hours. They are then smoothed between pasteboards by hydrostatic pressure.—To lessen the tedious mechanical operations connected with engraving, attempts have been made to obtain directly from the drawings, by chemical means, engraved daguerreotypes and photographic negatives for printing. Various processes have been devised, both in the United States and in Europe, to effect this object, some of which have met with a good measure of success. (See PHOTOGRAPHY.)

ENKHUISEN, a seaport town of the Netherlands, in the province of North Holland, on a small peninsula in the Zuyder-Zee, 27 m. N. E. of Amsterdam; pop. in 1867, 5,625. It has several churches, a fine town hall, several salt refineries, and a large cannon foundry. The town was formerly more important than at present, and it is said to have had at one time about 40,000 inhabitants. The harbor, being filled up with sand, is now nearly useless.

ENNEMOSER, **Joseph**, a German physiologist, born at Hintersee, in the Tyrol, Nov. 15, 1787, died at Egern, Upper Bavaria, Sept. 19, 1854. In early life he was a shepherd, but his love of learning induced several clergymen to send him to a gymnasium and afterward to the university of Innsbruck. Among his classmates was the celebrated Hofer, whom in 1809 he followed in the Tyrolese insurrection as secretary. At its close he resumed his studies, but in 1812 made an unsuccessful effort in England to raise means for its renewal, and then entered the Prussian service, distinguishing himself in the campaigns of 1813-'14 as commander of a company of Tyrolese, and especially as a staff officer. On the conclusion of peace he resumed his studies at Berlin, graduated as doctor of medicine in 1816, officiated from 1819 to 1837 as professor in Bonn, afterward practised his profession at Innsbruck, and in 1841 removed to Munich, where he gained a high reputation by his skill in the practical application of animal magnetism and by his writings on medical and physiological science. His most important

works are: *Der Magnetismus* (2d ed., Leipsic, 1844; translated into English by William Howitt, under the title of "Natural History of Magic," 2 vols. 12mo, London, 1854), and *Der Magnetismus im Verhältniss zur Natur und Religion* (2d ed., Tübingen, 1853).

ENNIS, a parliamentary and municipal borough and market town of Ireland, capital of the county Clare, on the river Fergus, 20 m. N. W. of Limerick; pop. in 1871, 6,101. The town is irregularly built, and the ruins of an ancient Franciscan abbey, founded in 1240, form its only noticeable architectural feature. It has three bridges across the Fergus, manufactories of linen and flannel, a valuable limestone quarry, large flour mills, and considerable trade in agricultural produce. The Roman Catholic chapel of Ennis is considered the cathedral of the diocese of Killaloe. On the site of the old court house there is a monument to O'Connell with a colossal statue by Cahill. Near the town is a county lunatic asylum.

ENNISCORTHY, a market town of Ireland, in the county and 13 m. N. W. of the city of Wexford, on both banks of the river Slaney, and on the railway from Dublin to Wexford; pop. in 1871, 5,804. The Slaney, which here becomes a deep and navigable stream, is crossed by a bridge of six arches. The town contains a castle, a large modern Roman Catholic church, built from the designs of Pugin, several Protestant churches, a woollen factory, flour mills, tan yards, and distilleries, two banks, and two newspapers. At the weekly markets much grain and agricultural produce is sold. Enniscorthy was captured by Cromwell in 1649, and was stormed and burned in June, 1798, by the Irish rebels, who a few days later were completely routed in the battle of Vinegar hill.

ENNISKILLEN, a town and parliamentary borough of Ireland, capital of the county Fermanagh, 89 m. N. W. of Dublin; pop. in 1871, 5,906. It is very picturesquely situated on an island connecting Upper and Lower Lough Erne, and on the adjoining mainland on both sides, which communicate with each other by two bridges. The town has a Roman Catholic and several Protestant churches, county buildings, and two barracks. It manufactures cutlery and straw hats, and there is a weekly market for flax, and others for butter and pork. Three newspapers are published. A railway, 32 m. long, connects the town with Bundoran, a favorite watering place on Donegal bay, near Ballyshannon. The town is noted for the victory achieved here in July, 1689, by its Protestant volunteers, over a detachment of James II.; and it has given its name to a regiment in the British service, which was originally raised from the defenders of the place.

ENNIS, **Quintus**, the father of Roman literature, born at Rudiae, a village of Calabria, about 239 B. C., died in 169. He claimed descent from a mythical hero, the first settler in his country; and after he had learned the

Pythagorean doctrine of transmigration, he boasted that the soul of Homer dwelt in him. Nothing is known of his life till the close of the second Punic war, when he appears as a soldier in the Roman army, and a friend of the elder Cato, by whom he was taken to Rome. There he taught Greek and Latin, but seems to have held no marked position till in 189 he made the Ætolian campaign under Fulvius Nobilior, gained the esteem of the elder Scipio, and received the rights of Roman citizenship. From this time his learning and the charm of his conversation attracted to his little dwelling on Mount Aventinus the most enlightened citizens. His contemporaries marvelled at his learning, which in thoroughness and extent was surpassed by few of the later Romans. Though a master of Greek literature, he gave a thoroughly national character to his own works. The principal of these, entitled *Annales*, was a poem in 18 books on Roman history, which he treated consecutively from Romulus and Remus to his own times, describing later events with greater fulness. This poem was popularly admired, and was the chief foundation of his fame. Though it appears to have existed in the 13th century, nothing but fragments of it gathered from the ancient writers now remains. These are sufficient to show that Ennius devoted great attention to his language, and contributed much toward harmonizing and perfecting the yet rough and uncultivated Latin dialect. He also wrote tragedies and comedies, and adapted the masterpieces of Æschylus, Sophocles, and Euripides to the Roman stage. Among his numerous short pieces, his epigrams, three of which, extending collectively to ten lines, have been preserved, were especially famous. The best collection of the fragments of Ennius is by Hesselius (4to, Amsterdam, 1707).

ENNS, or **Ens** (anc. *Anisus*, or *Anesus*), a river of Austria, rises in the province of Salzburg, on the northern slope of a branch of the Noric Alps, 12 m. S. of Radstadt, flows N. past that town, then E. N. E. through Styria, then N., partly separating the provinces of Upper and Lower Austria, and after a total course of about 120 m. enters the Danube 2 m. below the town of Enns. Its principal affluent is the Steier on the left. It is navigable to Hiefelau, about 60 m., and its upper part lies amid wild mountain scenery. Its chief value is in its great water power. The archduchies of Upper and Lower Austria are often distinguished as Austria above the Enns and Austria below the Enns.

ENNS, or **Ens**, a town of Austria, on the left bank of the river Enns, a little above its junction with the Danube, 9 m. E. S. E. of Linz; pop. in 1869, 3,784. It has two churches and a handsome council house, and manufactures of iron, steel, and cotton goods. The walls of the town were built with the ransom money paid for Richard I. of England. Enns occupies the site of the Roman station Lauriacum,

which was the scene of a cruel persecution of the Christians by Galerius in 304. A battle between the French and Austrians took place here Nov. 5, 1805. Near the town is the old castle of Ennsceek, containing many Roman antiquities and belonging to the princes of Auersperg.

ENOCH, the son of Jared and father of Methusaleh, born, according to the Biblical chronology, A. M. 622. He is called "the seventh from Adam" (Jude 14), to distinguish him from Enoch the son of Cain, who was the third from Adam. Eusebius infers from the title "father of astronomy," given him by an old writer, that he is the same whom the Greeks worshipped under the name of Atlas. We read in the Scriptures that "he walked with God;" and as to his departure from the world, we are told that "he was not, for God took him." His character is drawn by two apostles, Heb. xi. 5, 13, and Jude 14, 15. The latter passage has been the subject of much controversy, as it refers to a prophecy by Enoch, part of which it cites apparently in the language of the prophet himself. A prophetic work called the "Book of Enoch" is frequently mentioned in the patristic writings. It is noticed by Justin Martyr, Irenæus, Clement of Alexandria, Tertullian, Origen, Augustine, Jerome, Hilary, and Eusebius. Most of these considered it apocryphal, though Tertullian maintained its authenticity and defended it from the criticisms of his contemporaries. Bruce, the traveller, brought from Abyssinia three copies of the book in the Ethiopic language, which immediately excited great interest in Europe. Sylvestre de Sacy translated portions of it, and a complete English version by Dr. Laurence, professor of Hebrew at Oxford, appeared in 1821. In 1833 a second, and in 1838 a third revised edition appeared. The book is supposed to have been originally composed about the time of the Christian era, in the Hebrew or Chaldee language. The Ethiopic version was not made from the Hebrew, but from a Greek translation which is not now extant. It consists of a series of revelations supposed to have been given to Enoch and Noah, and is divided into five discourses. The first describes the fall of the angels, the judgment upon them and their offspring the giants, and the journey of Enoch through the earth and heaven in company with an angel. The second contains the parables in which Enoch relates the revelations of the spiritual world. The third treats of astronomy and the changes of the seasons. The fourth describes a dream in which Enoch beheld the course of events from the beginning to the coming of Messiah. The fifth consists of exhortations based upon the preceding parts. The best edition is Dillmann's, who published the Ethiopic text from five MSS. in 1851, and a German translation and commentary in 1853.

ENRIQUEZ GOMEZ, Antonio, whose real name was ENRIQUEZ DE PAZ, a Spanish dramatist, born in Segovia early in the 17th century.

He was the son of a converted Portuguese Jew, lived much in France, became a captain in the Spanish army, and fled from Spain to escape the inquisition on account of his alleged Judaism, to which religion he finally returned. His *Siglo pitagórico* (Rouen, 1647 and 1682; Brussels, 1727) is a mystical book, partly in verse and partly in prose, satirizing the ancient doctrine of transmigration; and he wrote other similar works, besides 22 comedies which were very successful on the stage, and some of which resembled Calderon's, especially *A lo que obliga el honor* ("The Duties of Honor"), contained with three other plays in his *Academias morales de las Musas* (Rouen, 1642; Madrid, 1660; Barcelona, 1701). Some of his plays were printed with the name of Calderon, and others with that of Fernando de Zarate, which led to the mistake that he was identical with the latter.—See José Amador de los Ríos, *Estudios históricos, políticos y literarios sobre los Judíos de España* (Madrid, 1848).

ENSINAL, a S. W. county of Texas, watered by some affluents of the Rio Nueces and Rio Grande; area, 1,610 sq. m.; pop. in 1870, 427, all white. The county is best adapted to stock raising. Water and timber are scarce. In 1870 the county produced 9,556 lbs. of wool, and contained 1,678 cattle and 5,778 sheep.

ENTAIL, an expression used in the old books for an estate in tail (mediæval Lat. *fedum talliatum*, from *taliare*, to cut off), signifying a truncated inheritance, as being carved out from a larger estate, or perhaps from the exclusion of certain heirs. For the nature of this species of inheritance, see **ESTATE**.

ENTERITIS (Gr. *ἐντέρον*, an intestine), a medical term denoting inflammation of the mucous membrane of the small intestine. It is most frequent in young children, being a rare disease in adult life. It is marked by redness, softening, and thickening of the mucous membrane, ecchymoses in its substance and beneath it, and serous infiltration of the submucous connective tissue. The symptoms of enteritis are a moderate febrile movement, pain, tenderness, and diarrhœa, with nausea and vomiting. The pain is restricted to a small part of the abdomen, or spreads over its whole surface, according as the inflammation extends to the whole or part of the intestines; it is commonly severest about the navel, and is always increased by pressure. This pain is generally the first manifestation of the disease. The brain usually but not always remains unaffected. As occurring in adults, this is not usually a fatal disease, but generally terminates in convalescence in about a week or ten days from the commencement of the attack. Acute enteritis is distinguished from dysentery, or inflammation of the large intestine, by the absence of tenesmus and the characteristic dysenteric discharges; from gastritis, or inflammation of the stomach, by the comparatively mild character of the general symptoms; and from colic by the presence of tenderness,

diarrhœa, and fever, and the absence of severe spasmodic pain.—The treatment usually adopted is a purgative at the outset, followed by opiates in sufficiently large doses to relieve the pain and diarrhœa, with warm fomentations to the abdomen.

ENTOMOLOGY (Gr. *ἐντομον*, insect, from *ἐντομος*, cut in, and *λόγος*, discourse), the branch of natural history which treats of insects, one of the classes of articulated animals. That part of the science which refers to the anatomy and physiology of the class will be treated under the head of **INSECTS**; and the particular descriptions of orders, families, genera, and species will be found under their various scientific and popular titles. This article will be devoted to the history of entomology, and to brief sketches of the principal systems of classification.—In entomology, more perhaps than in any other department of natural history, does the student feel the want of a natural classification; but, as the best authors have devoted very unequal study to different groups, from the impossibility of fully cultivating every portion of the immense field, no classification complete and natural in all its parts can be found. The nearly 100,000 species now described probably do not form one half of the total number in existence. If we take for a basis the comparative ratio which has been found to exist in Germany between insects and plants, that of 2 to 1, and extend this to the whole world, we shall have in round numbers at least 400,000 species of insects inhabiting the earth.—It appears that Aristotle, the father of natural history, separated insects from crustacea, and divided them into winged and wingless, subdividing these last into several natural minor groups so successfully as to excite the surprise and admiration of modern observers. From Aristotle we may pass over a period of 1,800 years, a blank as far as the progress of natural history is concerned, to the middle of the 16th century, when Gesner, a Swiss, revived the study of animals, leaving valuable papers on insects from personal observation, which were published after his death by Mouffet, in 1634. During the next 100 years Aldrovandus divided insects into two chief groups, land and water insects, subdividing them according to the structure of their wings and legs; Hoesnaegel made beautiful figures of them; Redi studied their origin and mode of propagation; Malpighi made a careful dissection of the silkworm; Goedart and Vallisnieri described the metamorphoses of insects; Leeuwenhoeck examined them microscopically; and Mme. Mérian studied the development of the lepidoptera, going to Surinam in her scientific zeal to continue her observations among the most gorgeous species. The writings of Swammerdam, a Dutch naturalist in the middle of the 17th century, created a new epoch in the annals of entomology. He studied the metamorphoses of insects, and from these introduced the first attempts toward a natural

classification. His system was as follows: I. Insects without a metamorphosis, changing their skin but not their form, as spiders, lice, wood lice, and myriapods. II. Insects with a metamorphosis: *a*, those moving in all stages of existence, at first wingless, then with rudimentary and finally with entire wings, including what are now called *neuroptera*, *orthoptera*, and *hemiptera*; *b*, motionless in the pupa state, but having limbs, including the *hymenoptera*, *coleoptera*, and *lepidoptera*; *c*, ovate pupæ, wingless and motionless, as the *diptera*.—John Ray, an English clergyman living in the latter part of the 17th century, was the first true systematist, and doubtless furnished Linnæus with many of the ideas afterward successfully worked out by him. In a "History of Insects," published after his death in 1705, is the following arrangement: I. Insects without metamorphosis, including—1, *apoda* (annulate worms) terrestrial and aquatic; 2, *pedata*, including the terrestrial (lice) and aquatic hexapods, the octopods (spiders), lobsters and crabs, the terrestrial polypods (centipedes and wood lice), and the aquatic polypods (*amphipoda* and *isopoda* of Latreille). II. Insects with metamorphosis, including—1, those with moving larvæ and pupæ (*orthoptera* and *hemiptera*); and 2, those with motionless pupæ, as *coleoptera*, *lepidoptera*, *diptera*, and *hymenoptera*. III. Insects with simple metamorphosis, moving through most of the stages, like the dragon flies.—Réaumur, in the early part of the 18th century, published his *Mémoires pour servir à l'histoire des insectes*, affording valuable information on the habits of insects, but wanting in systematic arrangement. About the same time, in 1735, appeared the *Systema Naturæ* of Linnæus, who displayed in the classification of insects the same intuitive perception of the characters of groups that is observable in his other branches of the animal kingdom. His system is based on the characters of the wings and the presence or absence of a sting, as follows: I. Insects with four wings, including the following orders: 1, *coleoptera*, with the anterior wings crustaceous, with a straight suture; 2, *hemiptera*, with semicrustaceous incumbent anterior wings; 3, *lepidoptera*, with all the wings covered with scales; 4, *neuroptera*, with all the wings membranous, and with no sting in the tail; 5, *hymenoptera*, with membranous wings and tail armed with a sting. II. Insects with two wings, comprising, 6, *diptera*, with poisers in place of the posterior pair. III. Insects with neither wings nor elytra, including, 7, *aptera*, in which were placed by Linnæus the hexapod lice, fleas, &c., spiders, crabs, and centipedes. The fault of this system is its exclusive principle of division drawn from the wings, which placed among the *aptera* animals far removed from insects proper.—De Geer, a Swede, published a work on insects between 1752 and 1778, having the same title as that of Réaumur, of which it may in some respects be considered the sequel; his system is intermediate between

that of Linnæus and that of Fabricius, who came after him, being based both upon the organs of flight and those of manducation, and according to Mr. Kirby is more natural than that of either of the above named naturalists. It is as follows: I. Insects with wings, *alata*, including—A. *Gymnoptera*, or those with four wings without cases, with the subdivisions: 1, *lepidoptera*, with scaly wings and spiral tongue; 2, *elingula*, with naked membranous wings, no teeth nor tongue (*trichoptera*, *ephemerina*); 3, *neuroptera*, with membranous, equal, reticulated wings, and teeth in the mouth (as *libellula* and other Linnæan *neuroptera*); 4, *hymenoptera*, with membranous unequal wings, teeth in the mouth, and a sting or borer in the females; 5, *siphonata*, with membranous wings and tongue bent beneath the breast (*homoptera* of Leach), including the *aphides* and *cicadæ*. B. *Vaginata*, or those with two wings covered by elytra, with the subdivisions: 6, *dermaptera*, with elytra half coriaceous and half membranous, crossed, a pair of membranous wings, and tongue bent beneath the breast (*hemiptera* of Leach), as the bugs and water bugs; 7, *orthoptera*, cockroaches and grasshoppers; 8, with teeth in the mouth, and the wings of beetles (*coleoptera*). C. *Diptera*, with two uncovered wings, including—9, *halterata* (the *diptera* of Linnæus), having a pair of poisers, mouth with a tongue without teeth; 10, *proboscidea* (like the genus *coccus*), with no poisers, tongue, or teeth in the male, and no wings, but a tongue in the breast of the female. II. Insects without wings, *aptera*, including—D. *Saltatoria*, with the subdivision: 11, *suctoria* (*culex*), undergoing metamorphosis, with six legs, and mouth with tongue, the *aphaniptera* of Kirby. E. *Gressoria*, with the subdivisions: 12, *aucenata*, undergoing no metamorphosis, with six legs, and head and trunk distinct, as *termes*, *pediculus*, *psocus*; 13, *atrachelia*, spiders and crabs; 14, *crustacea*, as isopods, amphipods, and myriapods. This system, though not purely artificial, and founded on several correct principles, is yet far from natural, and includes among insects animals which do not belong with them; his 14 orders comprised only about 1,500 species, referable to 100 genera.—Geoffroy, in France, in 1762, published a system which is important from the introduction of the joints of the tarsi as a means of classification; he makes only six groups, *coleoptera*, *hemiptera*, *lepidoptera*, *traptera*, *diptera*, and *aptera*, the third, fifth, and sixth being the same as the Linnæan; it is an exceedingly unnatural system.—Fabricius, a German, a pupil of Linnæus, introduced important improvements into the science during the last quarter of the 18th and the beginning of the 19th century; his system is based upon the number, proportions, form, and situation of the parts which constitute the mouth, without regard to other parts of the insect; by building upon this narrow foundation he departed widely from nature, though by drawing

attention to the maxillary system he has enabled his successors to define certain groups with considerable accuracy. His first classifi-

cation of 1775 was greatly modified in the course of his life, and the following was proposed by him in his *Entomologia* in 1798:

I. INSECTS WITH BITING MOUTHS.

A. Two pairs of mandibles.

a. The lower ones having palpi.

1. Free without covering.....
2. Covered.....
3. Connate with the labium.....
4. Distended, thin, coriaceous.....
5. Horny, strongly toothed, labium without palpi.....

1. Class *eleutherata* (beetles).
2. " *ulonata* (*orthoptera*).
3. " *synistata* (*neuroptera*).
4. " *piezota* (*hymenoptera*).
5. " *odonata* (*libellula*).
6. " *mitosata* (*scolopendra*).
7. " *unogata* (scorpions and spiders).

b. All without palpi.....

B. A pair of scissor-like maxillae.....

C. More than two pairs of maxillae.

1. Within the labium.....
2. Outside the lip, closing the mouth.....
3. Outside the lip, but covered by the palpi.....

8. " *polygonata* (*isopoda*).
9. " *pleistagnatha* (short-tailed crabs).
10. " *exochinata* (long-tailed crabs).

II. INSECTS WITH SUCTORIAL MOUTHS.

1. In the mouth a spiral tongue.....
2. A horny proboscis, with jointed sheaths.....
3. A soft, unjointed proboscis.....

11. Class *glossata* (*lepidoptera*).
12. " *rhynchota* (*hemiptera*).
13. " *antliata* (*diptera*).

The facility with which genera were determined by this system secured for it many followers, in spite of its unnaturalness; and Illiger, by uniting it with that of Linnaeus, considerably improved it. He made order 1 of Linnaeus correspond with class 1 of Fabricius; 2 L. with 2 and 12 F.; 3 L. with 11 F.; 4 L. (to which were added *termes*, *lepisma*, and *podura*) with 3 and 5 F.; 5 L. with 4 F.; 6 L. (with *pediculus* and *acarus*) with 13 F.; and 7 L. (without the above named apterous genera) with 6, 7, 8, 9, and 10 F.—Olivier, in the article *Insectes* in the *Encyclopédie méthodique*, follows chiefly the Linnaean classification, modified by Geoffroy and De Geer, making use of the wings and elytra, the parts of the mouth, and the joints of the tarsi in his divisions; he substituted the term *orthoptera* for the *dermaptera* of De Geer; in his order *aptera* are still included spiders, crabs, and myriapods. In Olivier's great work on *coleoptera*, in six large quarto volumes with nearly 400 plates, published between 1789 and 1808, may be found the largest collection of representations of this order yet known.—Latreille's first work, published in 1796, presents the insects of Linnaeus in 14 classes, adding *orthoptera* to the Linnaean system, and separating the *aptera* into *suctoria*, *thysanoura*, *parasita*, *acephala*, *entomostraca*, *crustacea*, and *myriapoda*; this system, though in many respects unnatural, claims the positive merit of introducing some natural families. In 1810 he adopted a new classification, following Cuvier and Lamarck in separating crustacea and arachnids from insects proper, and dividing the latter into the 7 orders of his first classification, adding the order *suctoria* (formed entirely by the genus *pulex*). In 1817 he added *myriapoda*, *thysanoura*, and *parasita* to his 8 orders, and also *strepsiptera* of Kirby; in 1825 he raised the *myriapoda*, after Leach, to a distinct class, and divided the *insecta* into 11 orders; in 1829 he reduced the *myriapoda* to an order among insects, raising the number again to 12 orders, and in 1832 raised them again to a class intermediate between arachnids and insects. One

great merit of Latreille is that he gave family names to the groups of genera, which Macleay has reduced to system by giving to them the termination *idae*, which, if not always classically correct, is of advantage for uniformity and euphony.—Lamarck divides insects into 8 orders: 1. Insects with suctorial mouths: 1, *aptera* (*suctoria*, Latr.); 2, *diptera*; 3, *hemiptera*; 4, *lepidoptera*. II. Insects with mandibulate mouths: 5, *hymenoptera*; 6, *neuroptera*; 7, *orthoptera*; and 8, *coleoptera*. Other *aptera* he placed among arachnids and crustacea, and ranked *thysanoura*, *myriapoda*, and *parasita* among arachnids.—Duméril places insects above mollusca in the animal series, and comprises among them arachnids and myriapods; his arrangement differs but little from the Linnaean; he endeavored to reunite the greatly divided families, and to reduce the number of genera.—The philosophical systems of the modern German school proceed on the view that organic nature is one great whole, exhibiting progressive grades of development, which are characterized as classes. Oken has made 13 classes of animals, each represented by a successively added organ. Insects form the 9th class, and are called *lung animals*; they are divided as follows: I. Germ flies, with perfect metamorphosis, with tribes: 1, *hemiptera*; 2, *orthoptera* and *dermaptera*; 3, *neuroptera*. II. Sexual flies, with perfect metamorphosis and equal wings, with tribes: 4, *diptera* and *suctoria*; 5 *hymenoptera*; 6, *lepidoptera*. III. Lung flies, beetles, with perfect metamorphosis, elytra, and wings, with tribes: 7, *C. tetramera*; 8, *C. heteromera*; and 9, *C. pentamera*.—Among the English writers who have contributed to the advance of entomological classification may be mentioned Leach, Kirby, and Macleay. Dr. W. E. Leach published several elaborate treatises on insects in the "Linnaean Transactions," and in the British and foreign encyclopaedias; his system is sketched in vol. iii. of the "Zoological Miscellany." He divides insects into *ametabola* and *metabola*, according to the absence or occurrence of metamorphosis, the former including 2 and the latter 14 orders;

he subdivides *orthoptera* into 3 orders, adding *dermaptera* (*forficula*) and *dietioptera*, and introduces also *omoptera* and *omaloptera*. The classification of Kirby and Spence, as given in vol. iv. of the "Introduction to Entomology" (1815-'26), is as follows: I. *Mandibulata*, or insects with mandibles, containing the orders: 1, *coleoptera*; 2, *strepsiptera*; 3, *dermaptera*; 4, *orthoptera*; 5, *neuroptera*; and 6, *hymenoptera*. II. *Haustellata*, or insects with suctional mouths, containing the orders: 7, *hemiptera*; 8, *trichoptera*; 9, *lepidoptera*; 10, *diptera*; 11, *aphaniptera*; and 12, *aptera* (all wingless insects breathing through tracheæ). It has been objected to this system that the 3d order is improperly separated from the 4th, and that the 8th forms naturally a part of the 5th. The system of Macleay is founded on the following principles: 1, all natural groups return within themselves, and consequently present themselves in the form of circles; 2, each of these circles contains five others, connected in the same way; 3, where the circles join, there are intermediate groups connecting them more closely; 4, the members of each, at the points where the circles meet, exhibit analogies. The animal kingdom consists of five circles, one of which, the *annulosa* (crustacea and insects), consists of five principal groups, which may be represented as follows:

The three orders of *ametabola*, *mandibulata*, and *haustellata* only concern us here. Of the first, the myriapods join the *crustacea*, and the *thysanoura* and *anoplura* (*parasita*) join the *mandibulata*. The *haustellata* and *mandibulata* he calls *insecta ptilota*; the former include *lepidoptera*, *diptera*, *aptera* (*suctoria*, Latr.), *hemiptera*, and *homoptera*; the latter include *trichoptera*, *hymenoptera*, *coleoptera*, *orthoptera*, and *neuroptera*. These two circles are contiguous in the *trichoptera* and *lepidoptera*, the genus *mystacides* (Latr.) of the former making the transition to *aglossa* (Latr.) of the

latter. Space will not permit the introduction of the families which he considers the connecting links between the orders of the two great divisions. This system, while it has many forced and unnatural affinities, presents much that is valuable in determining the groups of transition, which are found among insects as among other branches of the animal kingdom. His principal work, *Horæ Entomologica*, was published in 1819-'21.—Burmeister divides insects, according to the completeness of their metamorphosis, into *ametabola* and *metabola*, each group presenting both *haustellata* and *mandibulata*, and subdivided according to the form of the larva, the structure of the wings, and the internal organization. His system is as follows: I. *Insecta ametabola*, with imperfect metamorphosis; the larva, pupa, and perfect insect resembling each other, the pupa eating and moving about: A. Having a suctional mouth, with four fine setæ enclosed in a sheath, and the palpi wanting, with order 1, *hemiptera* (bugs). B. With a masticating mouth: a, with four unequal wings, anterior ones leathery, the posterior membranous and folded longitudinally and once transversely; prothorax free, and many biliary vessels; with order 2, *orthoptera* (locusts); b, with four generally equal wings, never folded; with order 3, *dictyoptera* (cockroaches). II. *Insecta metabola*, with perfect metamorphosis; the larva a worm, of 13 segments, with or without legs; the pupa motionless, or, if it moves, not eating. A. With suctional mouth: a, with two naked transparent wings, the posterior replaced by pediculated knobs; four biliary vessels; larvæ without feet; soft proboscis, with several setæ and a pair of palpi; prothorax not free; with order 4, *diptera* (flies); b, with four wings, generally covered with scales, six biliary vessels; larvæ with feet and a distinct head; the maxillæ forming a spiral tongue; prothorax not free, but closely connected with the mesothorax; with order 5, *lepidoptera* (butterflies and moths). B. With masticating mouth, or at least visible mandibles and palpi: a, with four equally large or long wings, with reticulated nervures; rarely more than eight biliary vessels; prothorax always free; with order 6, *neuroptera* (dragon flies); b, with four unequal wings, with variously branching nervures; larvæ generally without head or feet, yet sometimes with both; many biliary vessels; prothorax not free; with order 7, *hymenoptera* (bees, wasps); c, with four unequal wings, the anterior ones corneous; larvæ with head, with or without feet; four or six biliary vessels; prothorax always free; with order 8, *coleoptera* (beetles). In almost all these orders there are apterous families, genera, and species, whose place may be determined by their metamorphosis and the structure of the mouth; but they never form a distinct order like the *aptera* of Latreille. Burmeister maintains that all true insects undergo some metamorphosis, though in the apterous forms it may be difficult to detect it from the

absence of the wings; as his idea of an insect necessitates metamorphosis, however imperfect, he gives the name *ametabola* (applied by Leach to apterous insects) to all those with an imperfect metamorphosis, as there is no real difference in the process of development in each.—Westwood, in his "Introduction to the Modern Classification of Insects," in 1839, gives the following:

I. MOUTH WITH JAWS.	II. MOUTH WITH A SUCKER.
Order <i>hymenoptera</i> .	Order <i>diptera</i> .
Osculant order, <i>strepsiptera</i> .	Osc. ord. <i>homaloptera</i> .
" <i>coleoptera</i> .	" <i>aphanoptera</i> .
Osc. ord. <i>euplexoptera</i> .	" <i>heteroptera</i> (including the water bugs).
" <i>orthoptera</i> .	" <i>homoptera</i> .
" <i>neuroptera</i> .	" <i>lepidoptera</i> .
" <i>trichoptera</i> .	

—Stephens, in the article "*Insecta*," in vol. ii. of the "Cyclopædia of Anatomy and Physiology" (1839), divides insects into: I. *Mandibulata*, containing *coleoptera*, *dermaptera* (earwigs), *orthoptera*, *neuroptera*, *trichoptera*, (caddis flies), *hymenoptera*, and *strepsiptera*; and II. *Haustellata*, containing *lepidoptera*, *diptera*, *homaloptera*, *aphanoptera*, *aptera*, *hemiptera*, and *homoptera*.—Siebold (Burnett's translation), in 1848, gives the following classification: A. Insects without metamorphosis, *ametabola*, containing—1, *aptera* (*pediculidæ*, &c.). B. With incomplete metamorphosis, *hemimetabola*, containing—*a*, with suctorial mouth: 2, *hemiptera*; *b*, with mandibulate mouth: 3, *orthoptera*. C. With complete metamorphosis, *holometabola*, containing—*a*, with suctorial mouth: 4, *diptera*; 5, *lepidoptera*; 6, *hymenoptera*; *b*, with mandibulate mouth: 7, *strepsiptera*; 8, *neuroptera*; and 9, *coleoptera*. This is the same as the classification of Vogt, founded upon embryological principles; and the orders are the same as those of Owen, as given in the second edition of his "Lectures on the Comparative Anatomy and Physiology of the Invertebrate Animals" (1855), except that *homoptera* is substituted by him for *hemiptera*. The orders of Milne-Edwards, in his *Cours élémentaire d'histoire naturelle* (1855), are nearly the same as Siebold's, except that *aptera* is omitted, *rhypiptera* substituted for *strepsiptera*, and *anoplura* and *thysanoura* are added. The embryological system of Van Beneden (1855) is the same as the last, the term *strepsiptera* being reintroduced, and *parasita* substituted for *anoplura*.—Prof. Agassiz, in the "Smithsonian Contributions to Knowledge" (vol. ii., 1851), gives the following classification of insects from embryological data:

I. CHEWING INSECTS (<i>mandibulata</i>).	II. SUCKING INSECTS (<i>haustellata</i>).
<i>Neuroptera</i> .	<i>Hemiptera</i> .
<i>Coleoptera</i> .	<i>Diptera</i> .
<i>Orthoptera</i> .	<i>Lepidoptera</i> .
<i>Hymenoptera</i> .	

In this the subdivisions are made according to their transformations. From the fact that those undergoing complete metamorphosis have a

chewing apparatus in the early stages of their growth, which is gradually transformed into various kinds of suckers, he expresses the belief that the *mandibulata* are lower than the *haustellata*; and he also ranks *lepidoptera* highest among insects, and not *coleoptera*, as generally maintained. Mr. A. S. Packard, in his "Synthetic Types of Insects" (1872), makes seven sub-orders, viz.: *hymenoptera*, *lepidoptera*, *diptera*, *coleoptera*, *hemiptera*, *orthoptera*, and *neuroptera*.—Mr. Wilson in the article "Entomology" in the "Encyclopædia Britannica," Dr. Burnett in his translation of Siebold, and Mr. Westwood, give valuable lists of the authors on this science, arranged in chronological order; from them we select the following as among the most important writers since Latreille: in England, Donovan, Curtis, Wood, Rennie, Haliday, A. White, Doubleday, Shuckard, Hope, Newman, and Newport; in France, Jurine, Dufour, Godart, Guérin-Ménéville, Boisduval, Dejean, Lacordaire, and Blanchard; in Germany, Meigen, Ochsenheimer, Klug, Fischer von Waldheim, and Germar; in Sweden, Fallen; in America, Thomas Say, Dr. T. W. Harris, J. L. Leconte, S. H. Scudder, A. S. Packard, and Dr. Hagen. The most useful work on entomology ever published in this country is the "Treatise on some of the Insects of New England which are Injurious to Vegetation," by Dr. T. W. Harris, issued by order of the legislature of Massachusetts; the second edition was published in 1852, and the third, edited by Charles L. Flint, in 1862, with illustrations, at the expense of the state. In this work are adopted the seven following orders, as generally received by naturalists: I. *Coleoptera* (or beetles), with jaws, two thick wing covers meeting in a straight line on the top of the back, and two filmy, transversely folded wings; metamorphosis complete; larvæ generally with six true legs and sometimes with a terminal prop leg, rarely without legs; pupa with wings and legs distinct and unconfined. II. *Orthoptera* (cockroaches, crickets, &c.), with jaws, two opaque upper wings overlapping a little on the back, and two larger thin wings folded in fan-like plaits; transformation partial; larvæ and pupæ active, but without wings. III. *Hemiptera* (bugs and plant lice), with a horny beak for suction; four wings, of which the upper lie flat, cross each other on the back, and slope at the sides like a roof; transformation partial; larvæ and pupæ like the adults, but wingless. IV. *Neuroptera* (dragon flies, May flies, white ants, &c.), with jaws, four netted wings, the hinder the largest; with no sting nor piercer; transformation complete or partial; larva and pupa various. V. *Lepidoptera* (butterflies and moths), with a sucking tube; four scaly wings; transformation complete; larvæ with six true legs, and from four to ten prop legs; pupa with the cases of the wings and legs indistinct, and soldered to the breast. VI. *Hymenoptera* (bees, wasps, ants), with jaws; four veined wings, the hinder pair

generally the smallest; a sting at the end of the abdomen; transformation complete; larvæ like maggots, or slugs, or caterpillars; pupæ with the legs and wings unconfined. VII. *Diptera* (flies, mosquitoes, &c.), with a horny or fleshy proboscis, two wings and two balancers or poisers behind them; transformation complete; larvæ footless maggots, with the breathing holes generally in the hinder part of the body; pupæ usually incased in the dried skin of the larvæ, but sometimes naked, in which case the wings and legs are visible, and more or less free.—Among the smaller groups, the order *strepsiptera* (Kirby), or *rhypiptera* (Latr.), contains minute insects which undergo their transformations within the bodies of bees and wasps; the maggot-like larvæ live between the rings; the females are wingless, and never leave the body of their host; the adult males have two very short members instead of fore wings, and two very large hind wings; the sharp-pointed jaws are adapted for piercing rather than biting. Their systematic position is not precisely determined; Latreille places them between *lepidoptera* and *diptera*, though he thinks them most nearly allied to some of the *hymenoptera*. The order *aptera* (Leach), *suctoria* (De Geer), *siphonaptera* (Latr.), or *aphaniptera* (Kirby), is constituted by the flea tribe, which seem to be intermediate between *hemiptera* and *diptera*. The earwigs, included by most entomologists among *orthoptera*, form the order *dermaptera* (Leach), or *euplexoptera* (Westwood). The spider-flies, ticks, &c., alluded to at the close of the article *DIPTERA*, form the order *hymenoptera* (Leach). The May flies were separated from the *neuroptera* and elevated to an order *trichoptera* by Kirby. The *thysanoptera* of Haliday consist of the minute insects of the *thrips* tribe, generally classed with the *hemiptera*; other *hemiptera*, as the harvest flies, plant lice, &c., have been separated by the English writers under the name of *homoptera*. Burmeister has separated from *neuroptera* those species which undergo only a partial metamorphosis into the order *dictyotoptera*.—Naturalists generally have been disposed to rank insects in the animal scale below mollusca, though many of their vital functions, as of locomotion and perception, indicate a superiority in the former. Mr. Kirby and other English entomologists have accorded the precedence to insects, in opposition to Cuvier and Lamarck, who placed the mollusca first on account of their system of circulation. In the branch of articulata, the position of insects is well given by Oken, when he says that “*lepidoptera* are born as worms, then pass into the condition of crustacea, and are finally developed into true insects, exemplifying the natural order of gradation of the three classes of articulata.” For interesting and conclusive observations on the position that worms are the lowest, crustacea the intermediate, and insecta the highest among articulata, see the paper by Agassiz, above alluded to, in vol. ii. of the

“*Smithsonian Contributions*.” In vol. i. of “*Contributions to the Natural History of the United States*,” in the highest class (insecta) of articulata he establishes the three orders of myriapods, arachnids, and insects proper, the last therefore being the highest order of the highest class, and the *lepidoptera* (butterflies and moths) the highest division in this order.

ENTOMOSTRACA, the lowest order of crustaceans, deficient in the segments, feet, and abdominal appendages of the higher forms. They have normally five or six cephalic rings, and eight or nine posterior ones belonging to the foot series. They include the carcinoids, like *caligus* and *argulus*, minute forms, parasitic or marine and fresh-water fishes; the ostracoids, minute forms like the *daphnia* of fresh waters, with the larger marine cirripeds or barnacles; the limuloids, or horseshoe crabs; and the microscopic rotifers, radiate in appearance but crustacean in structure, whose organs of locomotion are cilia around the head. They appeared in the early Silurian age.

ENTOPHYTES. See **EPIPHYTES**.

ENTOZOA (Gr. ἐντός, within, and ζῷον, animal), a group of invertebrate animals, which during some period of their existence live within and derive nourishment from the bodies of other animals, and with few exceptions belong entirely to the class of helminths or worms. Animal parasites form in fact a sort of subfauna, and their number is only to be estimated by the extent of the animal kingdom. The classification of entozoa has been attempted by many eminent zoologists since the days of Rudolphi, who may be considered the father of helminthology; but only recently, and chiefly through the labors of a few observers in Germany, has it attained the position of a true science. Cuvier refers the entozoa to the class radiata, and subdivides them, following the plan of Rudolphi, into *tenuioidea* or tapeworms, *trematoda* or flat worms, *nematoidea* or round worms, and *acanthocephala* or hooked worms. More correctly, however, they belong to the articulata, though their type is a degraded one, and some of them even approach in structure the mollusca. Adopting this arrangement, we can best explain the progress and present state of heminthology by considering these subdivisions separately.—*Tenuioidea*, *cestoidea*, *sterehelmintha*, tapeworms. These parasites in their mature state inhabit the intestines of all classes of vertebrate animals. In their transitional state or immature stage they occur as cysts in the tissues and organs of such creatures as form the food of their true bearers or hosts. These cysts, of which the measles in swine are an example, in the early days of science were not looked upon as of an animal nature, and were called hydatids and acephalocysts; and not until the latter part of the 17th century was their true character recognized. In the 18th, many observers, and especially Götze, noticed that their heads closely resembled those of the tapeworms. His observations were

confined chiefly to the tæniæ of animals, and appear to have had little influence with the scientific men of the next century, who fell back again upon the old and easy theory of spontaneous or equivocal generation; and so it remained until 1844, when Steenstrup's theory of alternation of generation was applied to the problem, and Siebold and Dujardin published essays on the connection between the tæniæ and encysted forms of various animals. Their experiments and those of Küchenmeister, who must be considered the highest authority on the human helminths, cannot be given in detail here; suffice it to say that tapeworms have been produced in carnivorous animals of all kinds by giving them the encysted forms to eat, and the encysted varieties have been bred in others by administering the eggs or embryos of tæniæ. Tapeworms consist of three parts, viz.: head, neck, and colony of joints. The head is a minute object, usually square, and provided with varieties of sucking disks and coronets of hooks, by which it attaches itself to the walls of the intestine. The neck is slender and marked by transverse wrinkles, which gradually are converted into joints. With age these joints increase in number, and finally those first formed become ripe, while new ones are continually given out from the head to supply in turn the place of those discharged. Their growth is generally rapid, and some species attain a length of 100 ft., while others are only a few lines long. Considered as a simple individual, the tapeworm has very

limited power of motion, although a distinct layer of muscular fibre is found beneath the skin. This integument is soft, white, moist, and porous; and through this nutrition is probably carried on by absorption, though the only organs subservient to this function are two pairs of longitudinal canals running along each side of the joints, and united by transverse branches. The skin contains also innumerable roundish, concentrically marked, calcareous corpuscles, recognized only by the microscope, which serve undoubtedly as a sort of skeleton. They possess no nervous system. The sexual organs, however, are remarkably developed. When the oldest joints have become sexually mature (which period varies greatly in different species), they pass off spontaneously by the anus—sometimes by the mouth—of the animal which harbors them. These are flat, quadrangular, yellowish white, and in some species are detached singly, in others by groups. These proglottides, as they are called, are true hermaphrodites, contain the sexual organs and eggs or embryos enclosed within shells, and possess the power of moving about; so that they have often been mistaken for trematoda,

and in fact are now considered separate individuals. They discharge their eggs either through the genital opening or by self-destruction, which results either from the bursting of their walls or by decomposition. They affect chiefly moist places, and, leaving the manure in which they have been deposited, wander about amid the herbage, and may in this way be devoured; or they fall into water, and there bursting, discharge their eggs, which are thus borne far and wide, and find entrance to a proper soil for future development. They are not capable of a long continued independent existence, and may even be destroyed within the intestine of their host, scattering their eggs along this canal, though harmlessly; for Leuckart found by experiment that eggs introduced into the intestine before being subjected to the action of the gastric juice remain unchanged; but that when previously submitted to its influence and then placed within the intestinal canal, the embryos became free. Proglottides may even be swallowed entire by animals which wallow in moist manure, and thus introduce the eggs to their proper dwelling place. When once they have set their offspring free, their object is accomplished and they disappear. Each proglottis contains a

FIG. 1.—*Tania solium*, with different Views of the Head.

vast number of eggs, so that if one out of the many millions reaches a proper habitation the species will not decrease in numbers. The embryos are enclosed in firm shells constructed to resist a strong pressure from without, and are either brown or yellowish, and round or oval. They probably cannot undergo a great degree of dryness, heat, or cold, or exist very long in fluid, without the destruction of the animal within. The history of the *tania solium*, or common tapeworm, will best serve as an example of the usual method of development and transformation of the *cestoidea*, for it has been most fully studied on account of its frequent occurrence in the form of measles, and its important relation to man. This worm is improperly named, since many are sometimes found in the same intestine. It seldom attains a length of more than 20 ft., and is composed of 600 or 700 joints, which when mature contain myriads of eggs, and escape singly or at once into the outer world. The eggs being set free find their way into water or manure, and are thus scattered far and wide. One occasionally enters the stomach of man on lettuce, fruit, or unwashed vegetables, but more gen-

erally they are swallowed by the hog, whose filthy and omnivorous habits need only be considered to show how readily it may become infected. In either case the egg shell is destroyed by the process of digestion, and the embryo, a minute globular vesicle, armed in front with three pairs of sharp spines, begins its active migrations. It sets out on its travels by boring into the blood or lymph vessels of the stomach or intestine, and is borne along by their currents till it reaches the capillaries, where it renews its activity and bores its way out of the circulatory system into any organ to which chance has carried it. There can be no doubt about this fact, for Leuckart has discovered the embryo several times in the vena portæ. It is possible that the embryos may in some cases lose their hooklets in the vessels, and thus, being unable to proceed further, become encysted in the capillaries. Having reached thus a proper situation for higher development, it becomes surrounded by a new formation or cyst resembling the structure of the organ it may inhabit. If it happens to penetrate any serous cavity, this cyst is not formed, but otherwise the development is the same. This process goes on rapidly, so that in a week or two the cyst may be recognized by the naked eye. The spines or hooklets now drop off, the primary vesicle goes on absorbing nutriment, and by the second or fourth week a

lets. From this head bud out one after another numerous joints, which finally make up the mature worm. It may be easily understood how these small white cysts gain entrance into the stomach of man, for measly pork is often sold in markets, and although

FIG. 3. ^a

FIG. 4.
Cyst found in Swine.

thorough cooking and curing destroy the larvæ, still the cysts may adhere to the knife, and be thus transferred to vegetables, butter, cheese, and the like, which are eaten uncooked. It may often be the case too that pork is so slightly measly, that the butcher does not know the disease is present. There can be no question about the identity of these two forms, the *tænia solium* in man and the *cysticercus cellulosæ* or measles in swine; for not only are their heads anatomically the same, but it had for a long time been noticed that where measles in pork were abundant, there tænia was of most frequent occurrence, and that where the use of this flesh was forbidden among nations or sects, there tapeworm was scarcely ever found. All of this led to the belief, especially after the experiments performed in regard to the tæniæ and cystic worms of the lower animals, that the measles in meat were the cause of tapeworm in man. To settle this point Küchenmeister fed a condemned criminal three days before his execution on raw measly pork, and on examination after death the young tapeworms were found attached to the walls of the intestine. One point, however, remained to be proved, viz.: that the eggs of the tapeworm produce the measles in swine. For this purpose experiments were undertaken by the Saxon government under the direction of Küchenmeister and other scientific men of Germany. Young and healthy pigs were kept confined separately, and to them were given the eggs of tapeworms. At various intervals they were killed, and the encysted forms were found in myriads throughout the body. These experiments have been often repeated with the same success. To recapitulate: The tapeworm of the human intestine discharges millions of eggs, a single one of which need only reach maturity to produce millions more; therefore it is evident that the vast majority of these eggs perish undeveloped. These eggs must be devoured by some other host to reach their second or encysted stage. This stage is known as measles in swine. Measles being eaten by man in turn produce the tapeworm. These two forms never produce each other in the same individual.

FIG. 2.—Development of a Cyst.

protuberance grows out from its internal surface, which soon takes the form of the head of the future tænia. Upon this springs up a double circle of small hairs, which in six weeks become the complete double coronet of hooks. The neck now begins to extend, but the head still remains enclosed in the bladder, till the whole animal is set free. It may continue to live in this encysted stage till it dies of old age, unless set free by nature or art; and this undoubtedly is the fate of the largest portion of these immature creatures. If seated in the muscles, this encysted stage of tapeworm is seldom injurious to man; but if it take up its dwelling place in the brain or eye, which is not unfrequently the case, results most serious follow. In the hog the case is different, for many eggs being devoured at once, the embryos invade nearly every organ of the body, and produce the disease known as measles. We have still to consider the last and highest stage of development in the life of a tænia, viz.: the conversion of these cysts or measles into the mature intestinal worm. When one of these cysts is accidentally swallowed by man, the little pea-like vesicle bursts, and the head of the worm protruding fastens itself to the intestinal walls by its hook-

Various other tæniæ infest man in one of their stages, the most dangerous of which is the *echinococcus*, or encysted form of *E. hominis*. The cysts produced by this parasite are often as large as a man's head, causing great suffering and death. In Iceland every seventh person

FIG. 5.—*Tænia echinococcus*. a. Cyst, opened. b. Collection of Vesicles or Scoleces. c. Single Scolex greatly magnified.

is thus afflicted. The explanation lies in the filthy habits of this people, and in the great number of dogs they keep, which assist in spreading the seeds of the disorder. Here the cysts or hydatids contain instead of one scolex or head innumerable embryonic forms, which of course increases the risk of infection. The mature tapeworm produced artificially consists of but three joints, and on this account has hitherto escaped notice. Even now it is not known whether man himself or dogs are the hosts of the mature helminth. Another remarkable species dwelling in the intestinal canal of man is the *bothriocephalus latus*, or broad tapeworm. This differs from the true

FIG. 6.—*Bothriocephalus latus*, with View of Tail, magnified.

tæniæ in the construction of its head and joints. The former is oval, flat, and instead of a coronet of hooks and round suckers possesses two longitudinal sucking grooves on each lateral margin, by which it fixes itself; the latter are one third of their width only in length, and

the genital opening is found on the middle of each joint, instead of at the lateral margin, as in tæniæ proper, and occurs on the same surface throughout its whole length. They are sometimes as many as 2,000, but even then they do not make up a worm more than 20 ft. long. Thus far this parasite has been found in man only in its mature state. Its geographical distribution is limited to Russia (including Poland), Switzerland, Italy, and the maritime districts of France and north Europe, and it most probably undergoes its transitional stage of development outside the human intestine in some of the mollusks, which form the food of man. A few other species of tapeworm infest mankind, but they are seldom met with, and will be found enumerated in the accompanying catalogue. The dog, from his domestic and omnivorous habits, is made the host of many of these entozoa, and does much to keep up their precarious existence. Without his aid the *tænia caninus* would undoubtedly become extinct, and thus the sheep breeders would be rid of a disease which often proves so fatal to their flocks, viz., the staggers. This disease is caused by the presence in the brain of hydatids or cystic canuri, which when eaten by butcher and sheep dogs are converted into the corresponding tænia, the embryos of which are in turn scattered broadcast over the pastures, where they find ready admission to the grazing herds. This too has been made the subject of searching investigation in Germany, and shepherds are taught to keep their dogs free from this tapeworm, by putting out of their reach the flesh of animals afflicted with the staggers. Sheep may often be kept healthy by keeping them from moist places, and from pastures while the dew is still on the grass, for the proglottides seem to seek such localities, and the heat of the sun appears destructive to their vitality. Much more good may be effected by such preventive measures than by administering anthelmintics, or by attempting the removal of the cysts by the trephine or trochar. Very often immense droves of swine have to be slaughtered on account of the measles, and such attacks always prove that the victims

have lately been in the neighborhood of some person who has a *tænia solium*. Wild swine are never affected in this way. Occasionally this variety of *cysticercus* is found in the flesh of other animals eaten by man, as the ox, deer, and bear, but very seldom. No doubt a great deal of mealy pork is sold both fresh and salted, and enough is eaten in an uncooked state in the form of sausages, raw pork, and the like, to account for the wide distribution of tæniæ. Dr. Weinland, in his essay on human *cestoidea* (Cambridge, 1858), divides the *tenioidea* into two classes: First, the *sclerolepidota*, or hard-shelled tapeworms, the embryos of which, developed in the warm-blooded vertebrata, become mature tæniæ only in the intesti-

nal canal of carnivorous mammalia. Thus man obtains the *tania solium* from swine; the dog the *T. serrata*, *T. caninus*, and *T. echinococcus* from the rabbit, the sheep, and the ox respectively; the cat the *T. crassicolis* from the mouse; and so on. Second, the *malacolepidota*, or soft-shelled tapeworms, the eggs of which are to be hatched in the stomach of articulatæ and mollusks. The mature entozoa of this order inhabit the intestinal canal of such animals as prey upon the above, as fish, birds, and insectivorous mammalia.—*Trematoda, stercorintha* (Owen), isolated flat worms. These entozoa are characterized by their flattened, more or less elongated shape, and by ventral sucking disks. The same individual possesses the organs of both sexes. Rudolphi divided them into different genera, according to the number of cup-like suckers present. This classification has been given up, inasmuch as the more important distinctions of structure did not correspond to the external markings;

but many of the names have been retained. Thus the *distoma hepaticum*, or liver fluke, has two sucking disks. This, the best known of the trematode worms, resembles much a cucumber seed in form, and measures in length one inch, in width about half an inch. It is yellowish brown, probably owing to the bile in which it lives. In this class we first find evidence of an alimentary canal, in addition to the sexual organs, which gives it a higher rank than the *cestoidea*. This consists of a triangular opening or mouth, which may be used either as a sucker or means of obtaining nutriment. From this rises the intestinal canal. An excretory system is also present. This fluke has been found only in a few well authenticated cases in man. Its true home is in the gall ducts of sheep, and it is generally found in the same place in the human system. Cases are on record in which it has been found beneath the skin, having made its way thither by boring into the epidermis. In the liver of the lower animals it works sad havoc in autumn and winter, causing a dilatation and catarrh of the gall ducts, and an interference with the hepatic function, by which, of course, the secretion of the bile is disturbed and changed. They may occur in such quantities as to stop up the cystic duct, and their eggs are deposited in vast numbers in the bile. The symptoms they create in man need not be stated here. The passage of this worm by the stomach or intestines is the only proof we could have of its presence before death. The generation and development

of these worms had been a subject of great interest to naturalists, since Steenstrup made them the object of investigation in illustrating his theory of alternation of generation. The eggs of the *distoma*, escaping in the form of ciliated embryos, become converted while in the water into nurses or grand-nurses; that is to say, they are not themselves developed into young distomata, but produce in their interior several new organisms, which latter are the real young or larvæ of the future animal. These nurses are supplied with organs of self-support. The young brood, known as *cercariae*, possess in some species tails by which they undertake wanderings on their own account, become attached to mollusks or like animals, and thus find their way into the intestine and liver of some larger animal. The tailless brood have the power of encysting themselves while in the water, and may thus be borne about till they are swallowed by some of the herbivora. This is the general plan of development in all trematode worms, but it is not yet known what peculiar metamorphoses this entozoön undergoes. There can be little doubt, however, that sheep infect themselves by devouring snails which frequent the grass in moist meadow pastures, or by drinking ditch water. Whether "the rot" is actually caused by this parasite is not absolutely certain, though highly probable, as they are always found in this disease. Little benefit is to be derived from the use of anthelmintics, but a proper attention to these

laws of prophylaxis will aid the farmer much in preserving his flocks in a healthy condition. The *distoma hæmatobium* forms a very common disease in man in Africa, according to Bilharz, who found it first in the blood of the portal and mesenteric veins. But its chief habitation is the bladder and intestines, and when present in numbers it is very detrimental. In the bladder the worms fasten themselves to the mucous membrane, and produce patches of inflammation, exudation, and hæmorrhage. The fungous excrescences thus caused are pedunculated, and often of the size of a pea. Within them the animals may be found, and on their external surface the eggs. In the ureters the inflammation they create is sufficient to pro-

duce stricture, and consequent atrophy of the kidney. Several other species of trematode entozoa have been found both in man and herbivorous animals. Some of them infest the eyes of animals, and are sometimes found in such prodigious quantities as almost to fill the cavity of the eyeball.—*Acanthocephala*, *stereimntha*, hooked worms. This group of entozoa, which resembles the *nematoidea* in form and distinction of sex, approaches more nearly the *trematoda* in its digestive system. It includes some of the most noxious of the parasitic helminths, but none infest man. They are included under one genus, *echinorhynchus*, which is characterized by its retractile proboscis, armed with recurved spines. It is found in the intestines of the hog and other animals.—*Nematoidea*, *caelmintha* (Owen), or round worms. This class is made up of the round worms which inhabit the intestine, lungs, and kidneys of man and the lower animals, or else are enclosed within cysts in the muscular system or beneath the epidermis. They too undertake migrations and undergo transformations, but we are less acquainted with their development than with that of the first two classes; all that we know of them is, that we find sexually mature and embryonic forms, but to trace a connection between them, or to discover their mode of growth, has hitherto been possible only in a few species. They are distinguished from the *cestoidea* and *trematoda* by a more elaborate digestive apparatus, by a nervous system, and by individuality of sex. Most of the species are oviparous, and the development of their eggs has been lately made the study of helminthologists. The ova are enclosed in hard shells, within which under suitable conditions the embryo is further developed by segmentation, till it breaks from its habitation, and comes forth either a perfect worm, or in an intermediate form, in which it wanders into the tissues of man and other animals, where it may undergo the encysted stage, and finally on escaping become the mature individual, when it has found again a suitable habitation. The largest of this class is the *strongylus gigas*, which belongs to the dog and other animals, but which has been found at rare intervals in the human kidney. It is a long, cylindrical, red monster, with a mouth made up of six papillæ. The male, as usual in the *nematoidea*, is the smaller, measuring from 10 to 12 in., while the female sometimes attains the length of 3 ft., and is half an inch in thickness. This sea serpent of the human entozoa seems really to cause very little trouble. Like the *ascaris*, its relative, its fine red color seems owing to a reddish oil secreted by the vacuoles of the skin. Another species, *S. equinus*, is very common in the intestine of the horse, and *S. longivaginus* has been found in the lungs and bronchial glands of man. The *ascarides* are very numerous, and inhabit the intestines of many animals. The *ascaris lumbricoides* is the largest which infests the human intestine. It is found all over the world, and

prefers the lower part of the small intestine. It is of a pale, pinkish hue, cylindrical and elastic, has pointed extremities, and varies greatly in size according to age and sex. The male measures from 4 to 6, the female from 8 to 18 in. in length. The head is trilobulate with a constriction below the papillæ, which serve as sucking surfaces. The intestinal canal is a straight tube piercing the centre of the worm from end to end. They are very prolific, and as many as 64,000,000 ova have been found in one female. These eggs when immature are triangular and very irregular in shape, but when impregnated are enclosed in oval shells, within which the process of segmentation is carried on.

Whether it is their nature first to go through a developmental stage outside of man, and to gain readmission in food or in drink, is not known. Their great number, sometimes 300 or 400 together, leads to the belief that they may under favorable circumstances reproduce themselves in the original host. Any opening between the intestine and any cavity of the body may prove a loophole for its passage, and in this way its presence in strange places, as the bladder or abdominal cavity, may be accounted for. At all events, it is impossible for it to make an opening through the intestine or any tissue of the body, for it is without the means of doing so.

The presence of *ascarides* has been attributed to illness and bad flour and bread. They are most abundant in moist localities, as seacoasts and river valleys, and they may gain admission to the intestines on raw fruit, or in mollusca and larvæ of insects, which abound in such places. Bad food or the want of food will undoubtedly cause their discharge, as well as illness, but only because they are starved out, and because bad food and sickness generate an unhealthy action in the intestine, which thus becomes disagreeable to them. So their discharge is more frequent in summer, but it is on account of the frequent diarrhœas which follow the eating of green fruits and vegetables, by which they be-

come sickly and are expelled, and not because they are generated by such food of itself; for it must take a long time for them to reach maturity, and they are seldom seen before this age. All attempts to produce these worms in the lower animals by administering eggs have thus far failed. The *oxyuris* or *ascaris vermicularis*, the thread or pin worm of the rectum, is the smallest of the human intestinal worms, the male being about two lines and the female five lines long.

FIG. 12.—*Trichina spiralis*.

Its structure resembles that of its larger relative, and its head is also three-lobed, faintly marked.—The muscles of man are sometimes found after death to present a sanded appearance, which is caused by the presence of innumerable little cysts scattered throughout their substance; these are generally isolated, but in immediate contiguity. These minute bodies when examined microscopically are found to contain immature worms coiled up in the narrowest compass. They are cylindrical and tapering, $\frac{1}{2}$ of an inch long by $\frac{1}{100}$ of an inch thick, and their name is *trichina spiralis*. Both in the hog and in the human subject they are sometimes found in great abundance in the muscular tissue, sometimes as many as 70,000 or 80,000 to the cubic inch. When first discovered in 1832, and for many years afterward, they were supposed to be harmless, no symp-

toms connected with their presence having been detected. It is now known that in the cases first observed the parasites had long lain quiescent in the muscular tissue, and that their recent introduction into the system forms one of the most dangerous affections to which the human race is liable. The true physiological history of *trichina spiralis* is as follows: When the muscular flesh of pork containing the encysted parasite is eaten in an uncooked or imperfectly cooked condition, the cysts are digested and destroyed in the stomach, but the worms themselves, retaining their vitality, pass into the small intestine. In this situation they lose their spiral form, and begin to increase in size; and by the fourth or fifth day they arrive at maturity, attaining a length of from $\frac{1}{3}$ to $\frac{1}{2}$ of an inch. At the same time the sexual organs are fully developed, copulation takes place, and the females become filled with mature eggs and embryos, which last are produced alive and in great abundance. These embryos, which are of minute size but in form similar to their parents, then begin to penetrate the walls of the intestine and to dispose themselves over the body. This causes at first an irritation of the intestine, which is usually the earliest symptom of the attack. Within a fortnight after the commencement of the symptoms the embryos are usually to be found scattered throughout the body and limbs, in the tissue of the voluntary muscles. They are still not more than $\frac{1}{14}$ or $\frac{1}{15}$ of an inch long. They soon become enclosed in distinct cysts, where they grow to the size of $\frac{1}{8}$ of an inch, and at the same time become coiled up in the spiral form. This period of the invasion of the muscular tissue by the parasite is one of great danger to the patient, being characterized by swelling and tenderness of the limbs, pain on motion, and general fever of a typhoid character. The attack is often fatal about the fourth week. If the patient survive that period, the trichinae become quiescent, cease their growth, and may remain without further development or alteration for an indefinite period. The only protection from danger of being infected with trichina from eating pork is to be sure that the meat is always thoroughly cooked throughout.—*Tricocephalus dispar* (fig. 13) is a nematoid worm which is found, rather rarely and in small numbers, in the cavity of the human cæcum, and exceptionally in the colon or in the small intestine. Its anterior or cephalic extremity is slender and filamentous, while its posterior portion is thicker and more robust. The male, when extended, is about $1\frac{1}{2}$ in. long; the female $1\frac{1}{2}$ to 2 in. The eggs are ovoid in form, $\frac{1}{100}$ of an inch in length, and marked at each extremity by a minute nipple-like projection. They are discharged into the cavity of the intestine, and the embryo is developed only after a considerable time. This worm is not known to give rise to any disagreeable symptoms.—One more of the human entozoa is sufficiently interesting to be mentioned here at length, viz.: the

filaria medinensis, or Guinea thread worm. This is confined to certain localities in the tropical regions. It is seldom over 9 ft. long, and is found of all lesser sizes according to its age. The male has not yet been described, for either its small size prevents detection, or else it never occurs in man. In shape the female resembles a flattened cord, one line in diameter. Its color is pale yellow, and it is viviparous. Its head is circular and armed with four straight pointed spines, by which it probably penetrates the tissues. It inhabits the subcutaneous areolar tissue, and chiefly that of the ankles, feet, and legs; but it has also been found in the abdominal parietes and arms. It often proves an endemic, attacking certain regiments in armies and sparing others. It appears to follow the rainy seasons, and to occur mostly in low and marshy districts. There can be hardly any doubt that this animal is an inhabitant of wet places, and that man infects himself only by allowing it to come in contact with his skin. Those who take great precaution against wetting their feet, sleeping on the ground, and bathing in marshy pools, generally escape it. The worm may lie coiled up or extended at full length beneath the skin. As many as 50 individuals have been observed in one person, but usually one alone occurs. If superficial, its growth may be watched from day to day, and it has been seen to increase more than an inch in 24 hours. It often lies concealed for a long time without causing any symptoms of its presence, and may thus be borne from one country to another. When about to open externally, a little boil is found on the skin, which either bursts or is opened, and the anterior end of the worm protrudes. It is removed by seizing this and making gentle traction. All that readily yields is wound about a compress, and bound down over the wound till the following day, when the process is repeated

FIG. 13.—*Tricocephalus dispar*.

2. Male, magnified.
3. Female, natural size.

till it is wholly extracted. Great care is taken not to break the worm, for serious results often follow such accidents. It is probable that the young or germs inhabit wet soils, and enter the tissues of other animals to attain their full development after being impregnated outside. The attempt of the mature female finally to escape seems to imply that, its end be-

ing accomplished, it would return to its former home, and deposit its young, where new hosts may offer themselves for their reception.—Many other less important varieties of these three classes of entozoa have been described.—*Medical Treatment.* The administration of drugs in the encysted stages of tapeworm would of course be useless, and their diagnosis is often a most difficult problem. The following remarks apply then only to the intestinal forms. Nothing should be done until the passage of joints gives the infallible sign of the presence of the worm. All statements of patients regarding their own symptoms must be received with much doubt. A long catalogue of fearful and frightful ills is ascribed to their presence, but probably in the majority of cases without any cause whatever. It is true that the worm feeds upon the nutriment of the patient, but this has not yet formed a part of his organization, and is not assimilated. Whether epilepsy is ever caused by tapeworm is a matter of great doubt, and more valid proof is needed to show more than a coincidence between the presence of the two. Some species cling more firmly than others, and are more difficult to dislodge. Of course, unless we obtain the head we fail, for the *scolex* may go on producing new colonies indefinitely. The only way to effect their removal is to render their habitation disagreeable to them. Various drugs (called anthelmintics) are employed to drive out these intruders. A brisk cathartic may dislodge one or two ascariides if present, or bring away a piece of tapeworm. Cowhage (*mucuna pruriens*) and tin filings are now seldom used. Santonine, the active principle of *santonica* or *semen contra*, is used in doses of 3 to 6 grains three times a day. The oil of wormseed (*chenopodium*) is used in doses of 5 to 10 drops. Spigelia or pinkroot, alone or with senna, is a favorite anthelmintic in the United States, and the bark of the pride of China (*melia azedarach*) in the south. Tansy and wormwood, though not frequently used, may be added to the list. The small worms in the rectum are best treated with injections, either of ice water, salt water, infusion of quassia, lime water, or decoction of aloes. The tapeworm is advantageously attacked with oil of turpentine, petroleum, the oleo-resin of male fern (*aspidium filix-mas*), pomegranate bark, kameela (from *Rottlera tinctoria*), or by koussou, the flower of *Brayera anthelmintica*. An emulsion prepared from the seeds of the common pumpkin has been used with very good effect, and has the merit of causing no disagreeable symptoms. Some of these drugs, as male fern, santonine, pomegranate, and koussou, produce more or less intestinal disturbance; and some, as santonine, pomegranate, spigelia, and azedarach, produce nervous symptoms. Benzine and picric acid have been suggested for destroying the *trichina spiralis*; but unfortunately the presence of this dangerous parasite is not likely to be recognized

while accessible in the intestine, except during an epidemic, and it is not probable that any drug has power to dislodge or affect him after he has made his way into the tissues. It is said that the disease of sheep called rot, which is accompanied by the presence of these parasites in the biliary passages, does not occur where the bog bean (*menyanthes trifoliata*) or tomentil grows, no matter how damp the pastures may be; nor are the sheep which feed in salt marshes or have salt mixed with their food subject to rot. No remedies as yet discovered are of any avail in the treatment of the *trematoda*, and their presence can only be correctly diagnosed when their passage into the outer world is observed. Among the *nematodea*, the *oxyurides*, or pin worms, are the most troublesome, on account of the intolerable itching caused by their nightly wanderings outside the intestine. No treatment can wholly remove them, but cathartics and cold enemata are the best remedies.—The bibliography of helminthology has received many valuable additions within a few years, since it has become a distinct science. For a more complete account of its progress the following books may be referred to: Rudolphi, *Entozoorum sive Vermium Intestinalium Historia Naturalis* (3 vols. 8vo, Amsterdam, 1808); Steenstrup, publications of Ray society, "Alteration of Generation" (London, 1845); Bremser, *Ueber lebende Würmer im lebenden Menschen* (4to, Vienna, 1819); Diesing, *Systema Helminthum* (2 vols. 8vo, Vienna, 1850); Dujardin, *Histoire naturelle des helminthes ou vers intestinaux* (Paris, 1844); Van Beneden, *Vers cestoides ou acotyles* (4to, Brussels, 1850); Leuckart, *Blasenbandwürmer und ihre Entwicklung* (4to, Giessen, 1856); Owen, "Lectures on Invertebrata" (8vo, London, 1843); Küchenmeister and Von Siebold, translated in Sydenham society publications (2 vols. 8vo, London, 1857); Leidy, "A Flora and Fauna within Living Animals" (Smithsonian publications, vol. v., 4to, Washington, 1853); Weinland "Human Cestoides" (8vo, Cambridge, 1858); Davaine, *Traité des entozoaires* (Paris, 1860); Leuckart, *Untersuchungen über Trichina spiralis* (Leipsic, 1860); Cobbold, "Entozoa" (London, 1864); and Pagenstecher, *Die Trichinen* (Leipsic, 1865).

ENTRAGUES, Catherine Henriette de Balzac d', marchioness de Verneuil, a mistress of Henry IV., born in Orleans in 1579, died in Paris, Feb. 9, 1633. She was a daughter of François de Balzac d'Entragues by his second marriage with Marie Touchet, a former mistress of Charles IX. After the death of Gabrielle d'Estrées (1599) she became the mistress of Henry IV., who presented her with 500,000 francs and signed a contract to marry her in the event of her bearing him a son, which he renewed Oct. 1, 1599, after having cancelled it at the instance of his minister Sully. But her miscarriage in July, 1600, prompted him to marry Marie de' Medici. He compensated

his mistress by making her marchioness de Verneuil; but she insisted upon remaining in the Louvre, making herself obnoxious to the king, and especially to the queen. She long declined to give up his written pledge to marry her, but finally returned it in July, 1604, in consideration of the payment of 100,000 francs. But instead of carrying out her promise of going to England, she remained in France conspiring against the king, involving in her scheme her father and her half brother, the count d'Auvergne, who were sentenced to death Feb. 1, 1605, but pardoned through her continued influence over Henry IV. She was herself almost immediately released from prison, and it was even asserted that the king again took her for a short period as his mistress, until she was supplanted by a new rival. The testimony of a maid of honor of the queen implicated her in 1610 in the assassination of the king; but this lady (Mlle. de Coman) was imprisoned for life for perjury, while the marchioness spent her remaining years in affluence on her estates. She bore two children to Henry IV., who were both legitimated: Gabrielle Angélique, who married the duke d'Épernon, and died in 1627; and Gaston Henri de Verneuil, born in 1601, who was nominated bishop of Metz while still a layman, but never received episcopal consecration, was created a duke and peer, married a daughter of Chancellor Séguier, and died in 1682.—See De Lescure, *Les amours d'Henri IV.* (Paris, 1863).

ENTRECASTEAUX, Joseph Antoine Bruni d', a French navigator, born in Aix in 1739, died at sea near the island of Waigeo, in the Pacific ocean, N. of Papua, July 20, 1793. He entered the naval service in 1754, gradually rose to the position of commandant of the French fleet in the East Indies (1785), and in 1787 became governor of Mauritius and the Isle of Bourbon. In 1791 he was sent by the French government in search of La Pérouse, who had not been heard from since February, 1788. He failed to detect any trace of him, but ascertained with great exactness the outlines of the E. coast of New Caledonia, the W. and S. W. coast of New Holland, Tasmania, and various other coasts. Accounts of his voyages have been published by De la Billardiére (2 vols., Paris, 1800), De Rossel (2 vols., 1808), and De Frémenville (Brest, 1838).

ENTRE DOURO E MINHO. See MINHO.

ENTRE-RIOS, a province of the Argentine Republic, bordered E., S., and W. by the rivers Paraná and Uruguay, whence its name (between rivers). It is bounded N. by Corrientes, E. by the republic of Uruguay, S. by Buenos Ayres, and W. by Santa Fé; area, about 30,000 sq. m., although a late but inaccurate official statement makes it 50,000; pop. in 1859, 87,500; in 1869, 134,271, including about 18,000 foreigners. The increase was largely due to the Paraguayan war and to political disturbances in neighboring provinces. The country is intersected

by a series of hills, none of which attain a greater elevation than 300 ft.; but toward the N. W. rises Mount Montial, with a surface equal to about one fifth of that of the whole territory. Extensive forests cover the plains, especially along the banks of the rivers, which latter are exceedingly numerous, and not a few of considerable magnitude. The climate is in general mild and equable, and is considered by Europeans to be very salubrious. Entre-Rios is essentially a pastoral province; over 8,000 of its inhabitants are *estancieros* or cattle farmers, with immense herds of horned cattle, sheep, horses, and swine. Wheat, maize, mandioca, sugar cane, peanuts, tobacco, and many kinds of fruit are produced in abundance. Cotton, until 1865 extensively cultivated, has since that time received but little attention, owing to periodical droughts, and the lack of hands to pick it. Cochineal, indigo, and cascarilla yield large crops spontaneously; and the silkworm has been introduced. The forests supply a great variety of valuable timber. Fine limestone abounds in many parts, and extensive quarries are worked along the margin of the Paraná; a kind of cement is found in several localities, and exported to Buenos Ayres. Other important exports are hides, horns, tallow, jerked beef, dairy produce, eggs, honey, and wax. Occasional inundations and the want of adequate roads are great drawbacks to the prosperity of the province. There are 78 primary schools, 25 public and 53 private; and these were attended in 1871-'2 by 3,691 children between the ages of 6 and 15 years, out of a total number of 36,840 children. The province is divided into departments, and these into *distritos de campaña*. Capital, Concepcion del Uruguay.

ENVERMEU, a small town of France, in the department of Seine-Inférieure, Normandy; pop. about 1,500. It is within a few miles of Dieppe, and contains the site of an ancient Frankish cemetery, explored from 1849 to 1856 by the abbé Cochet, and found to contain many valuable relics, among them bronze and gold jewelry, swords, sabres, bronze buckles, a Gaulish coin or rather ingot of gold, which presented on the reverse an ill-formed miniature horse (supposed to belong to the era of 270 to 100 B. C.), necklaces of glass beads, iron axes (*francisca*), accompanied by iron lances (*franceæ*), iron spurs, arrow points, iron daggers ornamented at the point with a plate of bronze and flanked by small knives, elegant bronze purse clasps, &c. The cemetery seems to have been circular, and was probably once covered by a tumulus, long since removed by the operations of agriculture.

ENZIO, or **Eutius**, a natural son of Frederick II., emperor of Germany, born in 1224 or 1225, died in Bologna, March 14 or 15, 1272. He was handsome, accomplished, and chivalric, and took a distinguished part in the contests of his father with the Guelphs. At the

age of thirteen he accompanied him to the battle of Cortennova, and about two years later his father caused his marriage with Adelasia, marchioness of Massa, the widow of Waldo Visconti, and the heiress of important possessions in Italy. On this occasion he was created king of Sardinia, but it was only a nominal dignity. A more substantial one conferred on him by the emperor was that of governor general of Lombardy and commander of the German troops against the Milanese. Gregory IX. excommunicated Frederick in March, 1239; the pope's anger increased the ardor of Enzo, and he conquered for his father many towns in Umbria. As commander of the emperor's naval force in 1241, he defeated, in conjunction with the Pisan fleet, the Genoese in the vicinity of Leghorn, near the island of Meloria (May 3), after a protracted engagement. A great number of prelates were on board the Genoese galleys, about to attend, in spite of the emperor's remonstrance, a council convoked at Rome by Gregory. All these prelates, about 100 archbishops and bishops and three legates of the pope, were captured; the total number of prisoners was estimated at 4,000. The booty taken from the Genoese comprised a large amount of money, and in token of this success the prelates were removed to prison in chains of silver. After this and other victories over the Guelphs, the Ghibellines were defeated, May, 26, 1249, in the bloody battle on the Fossalta. Enzo being captured, the Bolognese condemned him to perpetual imprisonment, and refused to release him, although the emperor was ready to pay any ransom. He continued in prison 23 years, surviving the sons and grandsons of Frederick, who all met with violent deaths.

EOCENE (Gr. *ἠώς*, dawn, and *καινός*, recent), the lowest division or earliest epoch of the tertiary formation or period. It was named by Sir Charles Lyell, who divided the tertiary period into three epochs, called respectively, according to time, eocene, miocene, and pliocene, under the generally existing belief that the eocene contained among its fossils from 5 to 10 per cent. belonging to existing species. It was known that the next older formation, the cretaceous, belonging to the reptilian age, contains no existing species, and therefore this lowest tertiary epoch was named for the purpose of expressing the idea that it was the dawn of the existing state of the testaceous fauna. Since the division was made and brought into general use, it has been found that all the species of the eocene epoch are extinct. The miocene, however, contains from 10 to 40 per cent. and the pliocene from 50 to 90 per cent. of species now existing. The eocene rocks are well developed in the London and Paris basins, the cities of London, Paris, and Brussels being built upon the formation; a circumstance which has tended to attract much attention to its study, as well as the numerous fossils which it contains, and by which it was

subdivided into lower, middle, and upper eocene, called also in the United States the Claiborne, Jackson, and Vicksburg epochs. It extends along a great portion of the S. E. coast of the United States, principally in Maryland, Virginia, the Carolinas, and the gulf states. The beds reach their most complete and distinct development in Mississippi and Alabama. Those of the Claiborne epoch or lower eocene, near Claiborne, Ala., consist of about 25 ft. of clay overlaid by a bed of lignite 4 ft. thick, and succeeding this marl with oysters, then marly arenaceous limestone, again succeeded by marl with oysters, upon which is sand with shells showing beach origin, the whole being about 125 ft. thick. In Mississippi the beds reach a thickness of 425 ft. The epoch is represented on the Pamunkey river in Virginia, and at Marlborough in Maryland, by dark greensands. In the upper Missouri there is a great lignite group 2,000 ft. thick, containing much lignite, numerous leaves of plants, and shells of mollusks; and a lignite formation also occurs in Texas. The beds of the Jackson epoch, or middle eocene, are represented at Jackson, Miss., and consist of lignitic clay and beds of white and blue marls, containing numerous marine shells, and remains of the *zeuglodon*, and extinct species of whale supposed to have been about 70 ft. long, whose large vertebrae, 18 in. long by 1 ft. in diameter, are found in such quantities in some places as to be used in making walls. The Jackson beds cross the state as a narrow band about 80 ft. thick, E. N. E. through Jackson and Scott counties. The beds of the Vicksburg epoch, or upper eocene, are represented at Vicksburg, Miss., and consist of: 1, lignitic clay, 20 ft. thick; 2, ferruginous rock of Red Bluff, containing numerous marine fossils, 12 ft. thick; 3, compact limestones and blue marls, with marine fossils, 80 ft. thick; making a total thickness of 112 ft. The Vicksburg group occurs in Munroe, Clarke, and Washington counties, Ala.; as limestone at Tampa Bay, Fla.; and as gray marl on Ashley and Cooper rivers, S. C. In the upper Missouri region there are freshwater beds 1,000 ft. thick, consisting of white and drab clays, layers of sandstone, and local beds of limestone; but they are considered by Leidy as miocene. In them are found the remains of the *titanotherium*, an herbivorous animal, somewhat resembling the modern tapir, and about twice the size of a horse.

ÉON DE BEAUMONT, Charles Geneviève Louis Auguste André Timothée d', commonly called the chevalier d'Éon, a French diplomatist, who owes his notoriety to doubts which long existed as to his sex, born in Tonnerre, Burgundy, Oct. 5, 1728, died in London, May 21, 1810. He was of good family, was well educated, became a doctor of canon and civil law, and an advocate before the parliament of Paris, and at the outset of his career applied himself with some success to literature. In 1755 Louis XV. employed him in a delicate diplomatic mission to

Russia in company with the chevalier Douglas. Favored by a beardless face, he assumed the dress of a woman, and, blending a woman's tact with a politician's cunning, gained the good graces of the empress Elizabeth, became her reader, and having bent her mind to the wishes of the French court, went back to Paris to announce his success. He immediately revisited St. Petersburg in male attire, passed himself upon Elizabeth as the brother of her former favorite, was again successful in his negotiations, and on his way back to France appeared as envoy at Vienna. Having held a commission in the army, he was promoted to a captaincy of dragoons in 1759, served with the forces on the Rhine, and acted as aide-de-camp to Marshal de Broglie during the latter campaigns of the seven years' war. He was then secretary of embassy, and afterward minister plenipotentiary, at London; but being superseded in 1763 by the count de Guerchy, and mortified by being named secretary to his successor, he published a complete account of all the negotiations in which he had been engaged, exposed many secrets of the French court, and reflected with equal severity upon friends and enemies. Among the victims of his slander was De Guerchy, who brought an action in the court of king's bench, in which D'Éon was convicted of libel in July, 1764, and was finally outlawed. He continued, however, to reside in England, subsisting for a time by borrowing and various expedients, and afterward on a pension which Louis XV. allowed him for secret services; and after the return of De Guerchy to France, he acted as the representative of the court of Versailles, though not officially recognized as such. About 1763 rumors respecting his sex, which received color from his adventure in St. Petersburg, his appearance, his manners, and the reports spread by De Guerchy, became common topics of conversation in the British capital; bets to a large amount were laid that he was a woman, and a wager of this sort became matter for a lawsuit, in which the plaintiff, having brought witnesses to swear that D'Éon was a female, obtained a verdict for £700. In 1777 he went to Versailles, where Louis XVI., for reasons which have never been made known, forced him to adopt a woman's dress. He returned to England in this garb in 1783, and supported himself in London by the sale of his library, by giving exhibitions of his skill in fencing with the famous M. St. George and Mr. Angelo, and by a pension from George III. On the outbreak of the revolution he offered his services in a military capacity; but they were declined, and he passed the rest of his days in poverty in England, retaining till his death the garb which had been forced upon him 33 years before. A post mortem examination left no doubt of his being a man. He wrote a number of historical, political, and other works. The *Mémoires* attributed to him are spurious.

EOS. See **AURORA**.

EÖTVÖS, József, baron, a Hungarian author and statesman, born in Buda, Sept. 3, 1813, died in Pesth, Feb. 2, 1871. His education was completed at the university of Pesth, and at the age of 17 he commenced his literary career by a translation of Goethe's *Götz von Berlichingen*. This was followed by two original comedies and a tragedy. In 1836 he travelled through Germany, Switzerland, France, and Great Britain. In 1838 he became the editor of the *Budapesti árvizkönyv*, a work in which the most eminent Hungarian men of letters took a part. He contributed to it a novel entitled "The Carthusian," which made him at once the favorite of the Hungarian public. A pamphlet issued by him on prison reform produced a deep impression. His eloquent defence of the "Emancipation of the Jews" was still more remarkable. In the great controversy about Kossuth's *Pesti Hírlap*, Eötvös espoused his cause, and published a pamphlet in 1841 defending him against the conservative leader Széchenyi. As one of the leaders of the opposition in the upper house of the Hungarian diet, Eötvös achieved a distinguished position. But whatever may have been his merit as an orator and a politician, it was eclipsed by his fame as a novelist. His novel *A falu jegyzője* ("The Village Notary," 3 vols., 1844-'6), in which he boldly exposed the abuses connected with the rule of the nobles in the counties, had a marvellous success, and was translated into German and English. In 1847 he produced a new novel on the revolt of the peasantry in 1514, entitled *Magyarország 1514-ben* ("Hungary in 1514"). During this time he also exerted great influence through the newspaper press. His articles in the *Pesti Hírlap*, now edited by his friend Szalay, especially on centralization, of which he became the champion, while Kossuth defended the autonomy of the counties, were collected in 1846 in a volume at Leipzig under the title of "Reform." After the outbreak of 1848 Eötvös was appointed minister of worship and public instruction under the Batthyányi administration. He brought forward a comprehensive measure for the improvement of education, which was strenuously opposed on sectarian grounds, but was warmly supported by Kossuth and adopted by the diet. Eötvös, however, withdrew from the cabinet on the assassination of Count Lamberg, and retired to Munich, but returned to his native country in 1851. During the period of the suspension of the Hungarian constitution he published his work on "The Influence of the Leading Ideas of the 19th Century on the State" (2 vols., 1851 and 1854, Hungarian and German by the author), and several political pamphlets. In 1856 he was elected vice president and in 1866 president of the Hungarian academy. In 1861 he became a member of the lower house of the Hungarian diet as representative of the city of Buda, from which time he actively coöperated with Deák for the restoration of the consti-

tution; and on the creation of the Andrassy cabinet in 1867 he entered it as minister of worship and education. This office he held till his death.

EZOZÖN (Gr. *ἥως*, dawn, and *ζῷον*, animal), a name given to certain forms found in the Laurentian rocks of Canada, Massachusetts, and other primordial regions, under the belief that they are the impressions of the earliest animal organisms which appeared on the earth. The serpentine rock in which they are found is far older than the lower Silurian, in the azoic series of authors; if these are of organic origin, they carry back the first appearance of animal life to a period much earlier than geologists have usually admitted. Dr. Carpenter, Dr. Dawson, and others regard the so-called *ezoön Canadense* as a protozoan, of the rhizopod or foraminiferous division, a jelly-like living mass, spreading over the bottom of the sea, secreting calcareous partitions, and thus forming small chambers or cells; the interior of which has been filled with serpentine deposited from the waters of the ocean. Dr. Dawson believes that it had several foraminiferal successors in these early periods. On the other hand, excellent microscopists and mineralogists deny its animal origin, and maintain that these are only imitative forms of inorganic material, the result of infiltration of waters and chemical agency. Specimens have been found in the limestone or serpentine of Newbury and Chelmsford, Mass., in semi-crystalline vein-like deposits in granitic gneiss, in isolated masses, and not in stratified deposits accessible to fossils. High authorities are enlisted on each side, but the evidence seems to preponderate on the side of its animal origin.—The term *eophyton* has in like manner been applied to what appear like the remains of a terrestrial flora found in Swedish rocks of eozoöual age; they seem like stems and long parallel-veined leaves of monocotyledonous plants allied to the present rushes; they apparently grew on the margin of shallow waters, where they were buried in sand or silt. The *E. Linnaeanum* of authors probably contains several species. This may also be a dendritic or imitative form, of inorganic material. It stands by the side of eozoön; the one being, in the present state of our knowledge, perhaps the earliest land plant, the other the earliest animal organism.

EPACT (Gr. *ἐπακτός*, added, inserted, excessive), a word formerly employed to denote the difference in time obtained by comparing any two periods, as the 11 days by which the solar exceeds the lunar year. Now it denotes generally the number of days between the last new moon and the first day of the next year. These epacts are counted in Roman figures from I. to XXVIII. When a new moon falls on the first of January, then the epact is 0, that of the next year XI., and that of the third XXII. But in continuing this calculation, 30 is subtracted from every number exceeding 30. The epact for the fourth year is therefore reduced

to III.; then for the following two years 11 is added again, and from the sum obtained for the 7th year, being greater than 30, that number is again subtracted. Every 19th year the epact is XVIII., after which the series is repeated. The epact does not give the exact age of the moon. In the Julian calendar the correction of the error in the lunar cycle is made at the end of 300 years; in the Gregorian calendar this error is assumed to amount to one day in $312\frac{1}{2}$ years. The epacts are used to determine Easter Sunday, on which the dates of all the other changeable feasts of the church depend.

EPAMINONDAS, a Theban statesman and general, born about 418 B. C., died on the battle field of Mantinea in 362. He was the son of Polymnis, a Theban who, though poor, was a member of one of the noble families. In his youth he was an earnest student of philosophy, and, while receiving an exceptional education in all respects, devoted himself especially to this study under the tutorship of the Pythagorean Lysis, to whose influence his contemporaries attributed many of his best characteristics. With Pelopidas, a man of congenial virtue, he was early connected by the ties of tried friendship, though the date of the battle in which he saved the life of his friend cannot be fixed. When the Spartans gained possession of the Theban citadel, the Cadmea, in 382, Epaminondas for a time refused to join in the plan for its recapture, through fear of useless bloodshed, to which the teachings of his philosophy made him particularly averse; but when the first decisive step had been taken, Archias and Leontiades, the Spartan tyrants, had been killed, and the affair had assumed the aspect of a revolution rather than a conspiracy, he at once came forward as a leader, and was among the foremost in the attack which induced the Spartan surrender (379). In 371 he acted as the ambassador for Thebes when the envoys from all parts of Greece came together at Sparta to negotiate treaties. Here he greatly distinguished himself by his eloquence in advocating against Agesilaus of Sparta the claim of Thebes to represent all Bœotia. This was disallowed by the assembled envoys. Thebes was excluded from the treaty altogether, and war between Thebes and Sparta was at once declared. Less than a month afterward the armies met at Leuctra, the Spartans being under the command of Cleombrotus. The Thebans, commanded by Epaminondas, assisted by Pelopidas, gave battle at once, by the advice of the former, and after a brief struggle won a complete victory. The triumph of the Thebans was clearly due to the new tactics invented by Epaminondas. The results of the victory were further secured by the union of Arcadia and the founding of Megalopolis; these measures, suggested by Lycomedes, but vigorously urged and in great part carried out by Epaminondas, at once opposed a strong obstacle to any further schemes of Spartan dominion.

This accomplished, Epaminondas and Pelopidas invaded the Peloponnesus (369), ravaged Laconia, freed Messenia from the Spartan yoke, founding a new capital for it on the site of the ancient Ithome, and appeared before Sparta, which escaped capture through the wise provisions of Agesilaus. To continue these conquests both Epaminondas and Pelopidas had retained their commands longer than the Theban law allowed; and on their return they were tried for this, but both were acquitted, with the enthusiastic approval of the people. In 368 Epaminondas again invaded the Peloponnesus, compelled Sicyon and Pellene to abandon their alliance with Sparta, and made an unsuccessful attack on Corinth. He returned home, it appears, without having pushed his advantage sufficiently to satisfy the Thebans; and this is given as the reason for his receiving no command in the expedition sent into Thessaly the same year to rescue Pelopidas from Alexander of Phæræ, into whose hands he had fallen. This undertaking failed, and the historians attribute the saving of the army from utter ruin to the efforts of Epaminondas. A year later he led a force organized for the same purpose, and this time achieved the delivery of his friend, without, it is said, engaging in a single battle. In 366 he again invaded the Peloponnesus, but without noteworthy military results. In the mean time the overbearing conduct of Thebes in all international matters, which Epaminondas had endeavored to restrain, produced a great defection among the Arcadians; this was increased by the cruel punishment of the revolted Orchomenus during the absence of Epaminondas in Thessaly, and by many acts of oppression toward the Bœotians and other allies and subject states. The long existing discontent and spirit of revolt was brought to a crisis by the arbitrary refusal of the Theban commander at Tegea to carry out his promised compliance in the ratification of a treaty between the Arcadians and Elis. When the Mantineans sent to Thebes a protest against some oppressive measures taken in connection with this act, Epaminondas defended the commander, and expressed himself in favor of the immediate war which he saw could alone preserve Theban supremacy. Acting against a formidable coalition of Grecian states, which both Athens and Sparta had joined, he for the fourth time invaded the Peloponnesus. The enemy concentrated his force at Mantinea. This was composed mainly of Achæans, Eleans, and Arcadians, while the old Agesilaus was approaching from Sparta, and the Athenian contingent was expected. Having vainly tried to provoke the allies to action before the arrival of the Spartans and Athenians, Epaminondas, aware of the circuitous route of Agesilaus, made a rapid night march from Tegea to surprise Sparta, which was saved by Agesilaus being apprised of the danger in time, and by the bravery of his son Archidamus and other

youths. Epaminondas now turned to surprise Mantinea while the enemy marched to the rescue of Sparta, but the arrival of the Athenians frustrated this attempt also. He finally determined on a pitched battle, which was fought on the plain between Mantinea and Tegea. The plan of the Theban general was similar to that adopted at Leuctra, and the issue would probably have been the same had not his advance been interrupted by a javelin wound. He fell with the point of the broken spear sticking in his breast. He was still alive, but the extraction of the spear head would have terminated his pain with his life. Having been assured that his shield was not lost and that the Thebans were victorious, he inquired for two of his generals, but was told that they were dead. "Then let Thebes make peace with the enemy," said he, and drew out the weapon with his own hand. In reply to his friends, who regretted that he died childless, he said: "I leave two fair daughters, Leuctra and Mantinea." He was buried on the field, and a column, bearing a shield with the device of a dragon, was erected on his grave.

EPANOMERIA, a remarkable town in the island of Santorin, the ancient Thera, in the Grecian archipelago, built on the face and edges of a tall cliff at the extremity of a promontory on the N. W. end of the island. The houses, many of which are excavated from the rock, are placed one above another, 15 or 20 deep, the lowest being 400 ft. above the water. They are approached by means of a winding road and staircases cut in the cliff, reaching from the base to the summit. Viewed from the sea, nothing can be more striking than the appearance of this town, with its dwellings high above the masts of the largest ships, or perched on the edges of frightful precipices. On the summit the scene is scarcely less singular, the road there in many places passing over habitations whose existence is denoted only by chimneys jutting up on each side.

ÉPÉE, Charles Michel, abbé de P, a French instructor of the deaf and dumb, born at Versailles, Nov. 25, 1712, died in Paris, Dec. 23, 1789. He studied theology, and gave in his adhesion to the doctrines of the Jansenists, on which account his bishop refused him ordination, unless he would sign a certain formula of doctrine. This he would not consent to, and though admitted to deacon's orders, he was told that he need not aspire to any higher ordination. He then studied law and was admitted to the bar; but at this juncture his old friend M. de Bossuet, a Jansenist, having become bishop of Troyes, offered him a canonry in his cathedral, and admitted him to priest's orders. Hardly was he established in what he hoped was his life work when his patron died, and was succeeded by an orthodox bishop, through whose influence he was suspended from the priesthood. Calling one day upon a neighbor, De l'Épée found that she had two daughters who were deaf and dumb, that a benevolent

priest had endeavored to convey some ideas to them by pictures, but that he was dead, and there was no one who could teach them. He resolved to undertake their instruction, but was not aware that any works had been written upon the subject. Some time after he accidentally obtained a copy of Bonet's *Reduccion de las letras*, &c., in Spanish, and learned that language in order to read it. But the idea of using the natural signs and gestures to communicate information to the deaf mute was unquestionably original with him. (See DEAF AND DUMB.) From 1755, the date of his first establishment of a school for deaf mutes, till his death in 1789, he supported the school entirely at his own expense. As it soon became large, and his patrimony was but small, he was compelled to exercise the most rigid economy. Even in his 76th year he deprived himself of fire in his own room in order to sustain his school, refusing to receive the children of those who were able to remunerate him, or to accept the gifts offered him by Catharine II. of Russia and Joseph II. of Austria. A bronze statue has been erected to the memory of De l'Épée at Versailles, and a bass-relief placed in the church of St. Sulpice by citizens of Sweden. In 1855 the centennial anniversary of the establishment of his school for deaf mutes was celebrated at Paris, and was largely attended by delegations from institutions for the deaf and dumb in other countries of Europe. De l'Épée wrote *Institution des sourds et muets* (2 vols., Paris, 1774), which was revised and republished in 1784 under the title *La véritable manière d'instruire les sourds et muets*.

ÉPERIES (Hun. *Eperjes*), a town of northern Hungary, on the Tarcza, capital of the county of Sáros, 142 m. N. E. of Pesth; pop. in 1869, 10,772, nearly all Germans and Slavs. It is one of the most ancient and interesting, and after Kaschau the handsomest of the towns of Upper Hungary. It is the seat of a bishop of the United Greek church, and has a Lutheran college embracing a theological institution and a gymnasium, and a Roman Catholic gymnasium. It carries on a brisk trade, chiefly in corn, linen, wine, and cattle, and has manufactures of earthenware and woollen goods.—In 1687 the imperial general Caraffa established here the famous bloody tribunal which caused the torturing and execution of a very large number of patriots, especially Protestants. The executions took place on the public square before the windows of the general, and death on the gallows was regarded as comparatively mild and merciful. In 1848 and 1849 Eperies was successively in the possession of the revolutionists, of the Austrians, and of the Russians.

ÉPERNAY, a town of Champagne, France, in the department of Marne, on the left bank of the river Marne and on the line of the Eastern railway, 20 m. W. N. W. of Châlons and 74 m. E. N. E. of Paris; pop. in 1866, 11,704. It is well built, and stands in the midst of a fertile and picturesque valley. In its suburbs are many

villas and large estates of much beauty, and the Marne, which is here crossed by a stone bridge of seven arches, is bordered by fine buildings and their grounds. Épernay is the leading entrepôt of the trade in Champagne wine, and immense vaults in which this is stored in great quantities are quarried in the chalk which underlies the neighborhood. The place has also a considerable trade in other products, and manufactures of hosiery, fine pottery, woollen thread, &c. It is the seat of a court of first resort, and has a communal college, a public library of 18,000 volumes, a parish church built in the Italian style and finished in 1832, a theatre, and a city hall of excellent architecture.—The town is very old, and during the reigns of the early Carolingian monarchs was the property of the church of Rheims. It was burned by Francis I. in 1544 to prevent its falling into the hands of Charles V., but the king afterward caused it to be rebuilt. It was a part of the dowry assigned to Mary Stuart, queen of Scots, and it was sold to pay her ransom in 1569. Henry of Navarre captured it in 1592, during the wars of the league; Marshal Biron fell in the attack. In 1642 it became subject to the duke de Bouillon, who gave in exchange for it the county of Sedan.

EPHAI, a measure in use among the Hebrews. As a liquid measure, it was the same as the bath or firkin, and contained about $7\frac{1}{2}$ gallons. As a dry or hollow measure, it was one tenth of the homer, and was equal to 10 omers or gomers. It held a little more than $1\frac{1}{2}$ bushel of our measure. But there was a difference between the measures, weights, &c., of the Hebrews before and after the captivity.

EPHEMERA (Gr. *ἐφήμερος*, that which lasts a day), the name given by Linnæus to a genus of insects of the order *neuroptera*, so named from their appearing in the winged state only for a day, though in the larva and nymph states they are said to live beneath the surface of the water for two or three years. Appearing above this, in the air, generally toward evening in fine summer weather, they provide for the continuation of their race and die. The body is long, slender, and soft, the wings of very unequal size, and the abdomen with long articulated appendages. They are usually called May flies. Though but frail and delicate insects, they have been found in certain districts in France covering the ground in such enormous numbers as to be collected by cart loads for manure. One species, the *ephemera albi pennis*, or white-winged, is sometimes seen in such quantities by the banks of rivers as to whiten the air and the ground like drifting snow.

EPHESIANS, Epistle to the, one of the canonical books of the New Testament. It consists of two parts, the first (ch. i. to iii. 21) being chiefly doctrinal, the second hortatory and practical. The epistle purports to have been written by the apostle Paul during his captivity. Its Pauline origin, generally recognized by the ancient church as well as by the

early heretical sects, was for the first time called into question by Usteri (*Entwicklung des Paulinischen Lehrbegriffs*, Zürich, 1824), Schleiermacher (*Einleitung in das N. T.*), and DeWette (*Einleitung in die kanonischen Bücher des N. T.*), chiefly an account of the style of the epistle, which in their opinion shows marked peculiarities. The Tübingen school, in particular Baur (*Paulus der Apostel*, 1845) and Schwegler (*Das nachapostolische Zeitalter*, 1845), disputes its Pauline origin, on the ground that the epistle contains doctrines which are entirely foreign to the genuine Pauline epistles. According to Schwegler, it contains the principles of the Montanists, while Baur believes it to be pervaded by Gnostic views. The majority, however, even of the theologians of the liberal schools (among them Reuss, Rückert, and Schenkel), defend its authenticity.—According to the opening words, the epistle was addressed “to the saints that are in Ephesus,” but the words “in Ephesus” are omitted in the most ancient manuscripts extant (Vatican and Sinaitic codices), and appear to have been unknown to the earliest church writers. Hence some theologians, as Grotius and Paley, have adopted the opinion of Marcion that it was addressed to the church of Laodicea, and that it really is the epistle to the Laodiceans mentioned in Coloss. iv. 16, and commonly supposed to be lost. Others, as Archbishop Usher, Bleek, and probably the majority of modern exegetical writers, maintain that it was a circular letter for the use of several churches. It was formerly the common belief that the epistle was written at Rome about A. D. 67; but the opinion, first advanced by David Schulz (*Studien und Kritiken*, 1829), that Cæsarea has better claims than Rome, has been adopted by a considerable number of prominent theologians, as Schneckenburger, Schott, Wiggers, Thiersch, Reuss, Meyer, and Schenkel, who generally assume that it was written about 60 or 61, simultaneously with the epistle to the Colossians and Philemon. Special commentaries on this epistle have been written by Matthiæ (1834) and Rückert (1834). See also Bleek, *Vorlesungen über die Briefe an die Kolosser, den Philemon und die Ephesier* (1865).

EPHESUS, one of the twelve Ionian cities of Asia Minor, on the S. side of the Cayster, near its mouth on the W. coast. It was said to have been founded by the Amazons, whose legend is connected with Artemis or Diana, the deity of Ephesus. Strabo says that it was settled by the Carians and Leleges, who were driven out by the Ionians. It was besieged by Cræsus, and passed successively under the power of Persia, Macedonia, and Rome. The Romans made it the capital of the proconsular province of western Asia, and the centre of a great commerce.—Its rich territory, central situation, and the energy of its Greek population gave Ephesus great prosperity. It was

the native place of Parrhasius, Heraclitus, Hermodorus, and Hipponax, the inventor of parody, and claimed to be the birthplace of Homer. But its chief glory was its magnificent temple of Diana, and the city did not fall into decay until the Goths destroyed the temple. The Ionian colonists found the worship of Diana established and the foundations of the temple laid. It was enlarged and seven times restored at the expense of all Asia. During the night on which Alexander the Great was born, in 356 B. C., this magnificent structure was burned to the ground by the caprice of a certain Eros-tratus, who avowed that he had no other object than to immortalize his name. While it was rebuilding Alexander offered to pay all the expense if he might be allowed to place his name upon it; but the Ephesians refused, and the temple was built by the people generally, the work extending over 220 years. It was

John also lived in Ephesus, and addressed to the church there one of the messages in the Apocalypse. It was the resort of sorcerers and magicians, and the "Ephesian letters" were celebrated magical charms, even to the 6th century. Several Christian councils were held here; the most important of which were the assembly of the bishops of Asia convoked in 196 to fix the day for the celebration of Easter, the third oecumenical council in 431, and the famous "robber synod" in 449. (See CYRIL OF ALEXANDRIA, and EUTYCHES.) About A. D. 260 the city was sacked by the Goths, who burnt the temple; but the final destruction of the latter is supposed to have taken place in the following century. During the Byzantine period Ephesus was the see of an archbishop, but it dwindled in population, its port became choked, and its plains, from want of drainage and cultivation, unhealthy. In

the 11th century it was attacked by Turkish pirates, who were, however, driven out. In the 13th century it was alternately in the hands of the Mussulmans and their foes, but in 1308 fell finally under the Turkish power, and was held by one or another Turkish sultan. The ancient city almost entirely disappeared before the modern era, even the site of the temple being lost, the ruins having been in great part carried away for the construction of later buildings, while the rapid formation of alluvial soil buried

Remains of an ancient Amphitheatre.

425 ft. long and 220 ft. wide, being the largest of the Greek temples, and four times as large as the Parthenon at Athens. It was magnificently decorated with sculptures by Praxiteles and a great painting by Apelles. The statue of Diana was of ivory, furnished with exquisitely wrought golden ornaments. The temple had the right of asylum, which extended to the land around it, and caused the city to be overrun with criminals until the limits were narrowed by Augustus. The medals of Ephesus under the emperors bore a representation of the temple, which was counted one of the seven wonders of the world. It was still the most notable thing about the city when St. Paul preached there in the year 54. The commerce of the place attracted many Jews in apostolic times, and this led the apostle Paul to found there a Christian church, and to remain there over two years. The apostle

many beneath the surface. Several small Turkish villages occupy the ground, the most important of which is Ayasalook, 48 m. S. of Smyrna by the railway to Aidin.—In 1864 an Englishman, Mr. J. T. Wood, found in the ruins of the Odeum four letters from Antoninus Pius to the Ephesians (A. D. 145–151), and in the great theatre one from the emperor Hadrian to the Ephesians, dated Sept. 27, 120; besides an inscription containing particulars as to the endowment and ritual of the temple of Diana. A clause in this inscription ordered that certain processions should go through the Magnesian gate to the great theatre, and thence through the Coressian gate back to the temple; this gave the first clue to the site of the temple. The great theatre appears to have been large enough to contain 50,000 persons. After clearing this out Mr. Wood discovered a gate which he supposed to be the Magnesian gate;

and outside of this, at a depth of 11 ft., was a road leading N. W., and on its side a row of bases of square piers such as might have supported a stoa or covered portico. This he supposed to be the stoa built by Damianus in the 2d century from the Magnesian gate to the temple, to shelter processions in bad weather. He discovered also another similar road from another gate, and standing at the point where these two roads would converge, he found in 1869 the angle of an enclosing wall, with an inscription to the effect that Augustus had built the wall around the temple of Diana out of the revenues of the goddess. This wall he traced for 1,200 ft. until it turned westward, and within this enclosure he found by sinking pits extensive Roman foundations, a mosaic representing a Triton, many inscriptions, a pavement of Greek character, and fragments of statuary, besides several drums of Ionic columns of white marble. In 1871 the wall of the cella on the south and remains of piers came in sight; and on the west were found the lower drum of a column nearly entire weighing $7\frac{1}{4}$ tons, with figures in high relief, portions of other drums, and the sculptured base of a column and an Ionic capital, according with Pliny's description of the 36 sculptured columns of the temple. Many of the fragments and inscriptions discovered have been sent to the British museum. S. E. of Mount Prion, near the city, is the grotto of the seven sleepers, who are said to have taken refuge here from the persecutions during the reign of Diocletian, and falling asleep to have waked 200 years after and come into the city. The tradition was received by Mohammed and embodied in the Koran, and the cave is a place of pilgrimage with Moslems and Christians. The names of the seven sleepers, and also of the dog Ketmehr which slept with them, are revered throughout the East as of talismanic power. Not far from here tradition places the grave of St. John the apostle.

EPHOD, one of the articles of the official dress worn by Hebrew priests, consisting of two parts, one covering the breast and the other the back, united upon the shoulders, and sometimes described as thrown over the shoulders, crossed upon the breast, and then carried round the waist to serve as a girdle for the robe. It was of two kinds: one of plain linen, for the priests; and the other, for the high priest, "of gold, and blue, and purple, and scarlet, and fine twined linen," richly embroidered. On the shoulders of the high priest's ephod were two onyx stones, set in gold, having engraved on them the names of the 12 tribes, 6 on each stone; and where it crossed the breast was a square ornament, called the pectoral or breast plate, in which were set 12 precious stones, each bearing the name of one of the 12 tribes engraved on it. The ephod was worn by others besides priests.

EPHORS (Gr. *ἐφόροι*, from *ἐφορᾶν*, to oversee), popular magistrates at Sparta. The origin of

the office seems to have been too ancient for its institution to be historically traced. The authority of the ephors was designed as a counterpoise to that of the kings and council. They were five in number, and chosen from and by the people without any qualification of age or property. The mode of their election is not known. Aristotle calls it puerile, and it is supposed to have been by lot. They held their office for one year, entering upon it at the autumnal solstice, the beginning of the Lacedæmonian year. They met daily and took their meals together, in the building in which foreigners and ambassadors were entertained. They had judicial authority in civil cases, and the power to scrutinize the conduct of all magistrates. In early times the privileges of the office were very great, and they were gradually increased, until even the kings were called before its tribunal, and the assemblies of the people were convened only by its authority. During the Peloponnesian war the ephors received foreign ambassadors, subscribed treaties of peace, and sent out armies; and even on the battle field the king was attended by two ephors as councillors of war. The ephorality is thought by Müller to have been the cause of the instability and final dissolution of the Spartan state. The kings were obliged to court popular favor in order to uphold their power, and thus, contrary to the spirit of the Spartan constitution, the government became a democracy. The ephors became at length associated with all opposition to the extension of popular privileges, and the office was abolished by Cleomenes III. (about 225 B. C.), but restored by the Romans.

EPHRAEM SYRUS, the most prominent instructor of the old Syrian church, and one of the most prolific theological writers of the early Christian church in general, died probably in 378. He was born at Nisibis or Edessa, and was educated by Jacob of Nisibis, who took him to the council of Nice. He entered on a monastic life, and carried on his philosophical studies, only coming out to preach and teach. His reputation for learning and piety was so great that he was elected bishop, but declined the office. He spent the greater part of his life in writing and preaching on devotional and moral subjects, and against the heresies of his time, especially Arianism. When Edessa was suffering from famine, he called on the rich to assist the poor, and saw that the latter received what was intended for them. He was called by his countrymen the cithara of the Holy Ghost, and, because he transplanted Greek learning into the Syrian church, the prophet of the Syrians. His commentaries extended over the whole Bible. Hymns and prayers which are ascribed to him are still in use in the Chaldean, Syrian, and Maronite churches. Some of his numerous works are extant in the original Syriac, many others exist in Greek, Latin, and Armenian translations, and many are lost. The most complete edition is that of Rome (6 vols., 3 con-

taining the works in Syriac and Latin and 3 the Greek texts, 1732-46). A good German translation of a large portion of his works was published by Pius Zingerle, at Innsbruck (1830-38). A tasteful English translation of several hymns, songs, and homilies was made by Henry Burgess ("Select Metrical Hymns and Homilies of Ephraem Syrus," 2 vols., London, 1853). Bickell has edited *Ephraemi Syri Carmina Nisibena, additis Prolegomenis et Supplemento Lexicorum Syriacorum* (2 vols., Leipsic, 1866).

EPHRAIM, second son of Joseph, the founder of the tribe of Ephraim. The tribe occupied one of the finest and most fruitful territories of Palestine, in the very centre of the land. It included most of the province afterward called Samaria, and contained many of the most distinguished places of Palestine between the Jordan and the Mediterranean, having the tribes of Dan and Benjamin on the south and of Manasseh on the north. It was crossed by the mountain range bearing its name. The tribe of Ephraim often appears as the representative of the ten tribes, or the northern Hebrew state, both in historical and prophetic passages of the Scriptures. It held for a long time the ark and the tabernacle at Shiloh. Next to Judah it was the most warlike of the tribes, and gave to Israel several celebrated leaders and kings.

EPICHRMUS, a Greek dramatic poet, born on the island of Cos about 540 B. C., died in 450, or according to Lucian in 443. He went to Syracuse about 483, and there passed the remainder of his life. He conceived the idea of transforming the loosely constructed farces of which the Sicilian comedy consisted into pieces as regular and correct as the Athenian tragedies. He effected as great a reform in comedy as Æschylus in tragedy, diminishing the number of the actors, and introducing a more elegant and poetic language and a more elaborate plot. He was the author of 52, or according to some of 35 comedies, of which only the titles remain. His works were especially esteemed by Plato, who makes many quotations from them.

EPICETETUS, a Roman Stoic philosopher, born in Hierapolis, Phrygia, in the 1st century of our era, died in the first half of the 2d century. In his youth he was a slave of Epaphroditus, one of the guards of Nero. Epaphroditus having struck him heavily on the leg, he said to him, "You will break my leg." The prediction was speedily fulfilled, when the philosophic slave said again calmly, "Did not I tell you you would break it?" This extreme insensibility to pain was a fundamental principle in the philosophy of Epictetus. He became a freedman, though neither the cause nor the time of his emancipation is known. He was involved in the proscription by which Domitian banished all philosophers from Rome, and retired to Nicopolis in Epirus, where he opened a school of Stoic philosophy, and held those conversations which have been preserved

in the "Manual" and "Philosophical Lectures" compiled from his discourses by his pupil Arrian. Like the other Stoic philosophers, he taught by his example. He esteemed philosophy to be neither profound speculation nor eloquent discourse, but the love and practice of virtue. His teachings are summed up in the formula, "Bear and forbear." Recognizing only will and reason, his highest conception of life was to be passionless under whatever circumstances. "Man," he said, "is but a pilot; observe the star, hold the rudder, and be not distracted on thy way." Epictetus himself is supposed to have committed nothing to writing. The best edition of all the remaining works of Arrian is that of Schweighäuser, in the collection entitled *Epictetæ Philosophiæ Monumenta* (5 vols. 8vo, Leipsic, 1799-1800). They were translated into English by Elizabeth Carter (London, 1758). A new translation by T. W. Higginson, with a sketch of Epictetus, appeared in Boston in 1865.

EPICURUS, a Greek philosopher, born in the island of Samos in 342 B. C., died in 270. When 18 years of age he went to Athens, where he became a pupil of Pamphilus, and an admirer of the doctrines of Democritus. He travelled for several years, and in his 36th year established a school of philosophy at Athens, to which his fame soon attracted a great number of pupils. With them he constituted a community which has always been considered as a model of its kind. He enjoyed the respect and love of his followers to such a degree that his sayings had almost the value of oracles. No other ancient school of philosophy has evinced a cohesive power equal to that of Epicurus. Epicureanism has become almost a synonyme of sensualism, or at least a refined voluptuousness, but nothing was further from the meaning of his doctrines. It is true that he taught *εὐδαιμονία* to be the highest end and purpose of human life, but this word was intended to designate a state of supreme mental bliss, to be attained only by temperance, chastity, and a healthy intellectual development. That bliss, consisting in a perfect repose of mind, in an equilibrium of all mental faculties and passions, is perhaps not very different from the state of mind which the Stoics considered the acme of human perfection, although they were the most unrelenting adversaries of Epicureanism. Epicurus was a man of unsullied morality. Diogenes Laërtius estimates the number of his works at 300 or more. He boasted of having never used any quotations in order to swell his volumes. Few of his writings have been preserved, but a full analysis of his doctrines is to be found in Diogenes Laërtius, and this, taken in connection with numerous passages in the writings of Lucretius, Cicero, Pliny, and others, gives us a full insight into his philosophical system. Within the present century a fragment of his book on nature has been recovered from the ruins of Herculaneum, and published by Orelli

(Leipsic, 1818). Philosophy, according to Epicurus, is the exertion to obtain happiness by reasoning. The supreme bliss (*eudaimonia*) is enjoyment and perfect freedom from pain. Enjoyment is either passive, when a perfect repose of mind is its principal condition, or active. The former is preferable to the latter. It is the state of absolute freedom from pain. Sensations, whether agreeable or disagreeable, are of the same nature; it is only the consequences which constitute their difference. Hence it is the province of reason to discern them according to the ultimate effect they produce. Virtue in itself, irrespective of its consequences, has no value. It is merely the result of wisdom and sagacity, which prove to man that happiness is only to be attained by charity, peacefulness, temperance, patience, self-command. Human or natural rights are merely restraints of individual action, imposed by the necessities of social life. It is self-interest which enjoins us to do right. The repose of mind which constitutes human happiness being continuously disturbed by the uncertainty of the relations of man to the universe and divinity, Epicurus proposed to dispel that uncertainty by a reconstruction of the atomistic theories of Democritus in the following manner: Nothing comes from nothing. That which exists can never be annihilated. All matter consists of atoms, and these are unchangeable and indivisible, although filling a certain space. Besides shape, volume, gravity, and motion, they have no properties. Their number is infinite, their shape infinitely varied. The universe is infinite, and, considered as a unit, unchangeable; for the aggregate quantity of matter remains always the same, however its component parts may combine. The universe cannot be the product of divine action, or else the existence of evil could not be accounted for. The atoms, blindly drifting through infinite space, and declining somewhat from their course (through an accidental cause, whose nature Epicurus fails to explain), are mingled together, shove and push one another (the chaos), until the homogeneous ones associate. The light round atoms (the atoms of fire) are pushed upward, where they form the celestial bodies; those which are somewhat heavier form the air, while the heaviest are precipitated as water and earth. In a similar way the different objects on earth are formed. But the whole process is merely an accidental aggregation of atoms; higher ends and divine laws are mere inventions of the human mind. The psychology of Epicurus flows directly from his natural philosophy. The human soul, according to him, is a delicate and extremely mobile substance, consisting of the minutest round atoms. Its elements are warmth, air, breath, and another nameless substance on which sensibility depends. While the three first named are distributed through the whole body, the fourth has its seat principally in the pectoral cavity, and is, as it were,

the soul of the soul. The soul is not immortal; nevertheless death is by no means to be considered as an evil, since after death no consciousness of annihilation remains. Of all objects filling space infinitely delicate images are secreted. These images, coming into contact with the organs of sense, create perceptions. The conceptions of imagination are arbitrary combinations of such delicate images of real objects. By frequent perceptions the human mind attains to general abstractions, which are merely collective conceptions of the features common to a larger or smaller number of individual perceptions. Since the senses are the receivers of mechanical secretions of objects (images), the knowledge obtained through them is real and objective, the only correct standard of truth; but the workings of imagination, being likewise the result of sensitive perception, although an indirect one, point also to existing realities. Hence it follows that the universality of the belief in the existence of a Supreme Being is proof conclusive of such existence. The gods are living beings, of human shape but colossal proportions. They also consist of atoms. They are immortal, although their bodies are similar to the human body. This contradiction is explained by a certain equilibrium of contrasts in the universe. The gods are living in eternal bliss, that is to say, in absolute inactivity, in the quiet enjoyment of sublime wisdom and virtue. The spaces between the different celestial bodies (*intermundia*) are the seats of the gods.

EPIDAMNUS. See DYRRHACHIUM.

EPIDAUROS (now *Epidavro*), an ancient city of Greece, on the eastern shore of the Peloponnesus, on the Saronic gulf, nearly opposite the harbors of Athens, from which it was distant only a six hours' sail, in the district called Argolis after the decline of Grecian power. Throughout the period of the country's greatness the city and its adjacent territory formed a small independent state. According to Strabo, it was founded by a Carian colony, and originally named Epicarus. It subsequently received an Argive colony, and became a part of the Doric league, of which Argos was the head. It severed its connection with Argos, however, and during the Peloponnesian war was an ally of Sparta. It had an aristocratic constitution, was an important commercial city, and colonized Ægina; but it rapidly declined in the 6th century B. C., its commerce passing into the hands of the Æginetans. It was chiefly distinguished for its splendid temple of Æsculapius, bearing the inscription, "Let only pure souls enter here," which stood five miles west of the city on the road to Argos, between two mountains, in a thickly wooded grove, in which it was unlawful for any one to be born or to die. The temple was near the centre of this sacred grove, and contained a gold and ivory statue of the god. Near the temple were the Tholus, a circular structure containing medicines for all diseases, a theatre, the bath of Æsculapius,

and temples dedicated to other divinities. Pilgrimages were made to this temple by the sick, and every four years a festival was celebrated here. It was plundered by the Romans. Some of its foundations are still traced, and the theatre is one of the best preserved of all the old Greek edifices. The modern Epidavro is a small village, noted as the place of assembly of the first Greek congress in 1821, which promulgated the constitution called after the place.

EPIDEMIC DISEASES (Gr. *ἐπί*, upon, and *δῆμος*, people) are those which attack at the same time a great number of persons in a given locality, depending on some temporary, accidental, and generally inappreciable cause; differing in this respect from endemic diseases, or those developed under the influence of some constant or periodic cause. Many diseases, ordinarily sporadic, may become epidemic under certain ill-understood conditions; or some new disease, introduced by contagion or other favorable circumstances, may spread epidemically. Having ascertained the cause, or the epidemic tendency of the season, the treatment must depend on the nature of the disease and the constitution of the patient; even when remedial measures seem powerless, the physician can do much to check an epidemic by inspiring confidence and moral courage, and by withdrawing the attention of a community from the continual consideration of any supposed causes. The human constitution may become acclimated to epidemic diseases in malarious climates, as is shown by the greater mortality among new comers. In the white races there is no acclimation against endemics of intermittent and bilious fevers and other marsh diseases, as the experience of our southern states and the Pontine marshes of Italy fully proves. Negroes to a certain extent become insusceptible to the effluvia of the rice fields, but not so much so to the causes of disease on the cotton plantation; they suffer more than whites from cholera, typhoid diseases, plague, and smallpox, but are much less liable to intermittents, and the smallest admixture of negro blood is a great protection against yellow fever. (See **ACCLIMATION**.)

EPIDERMIS, or *Cuticle*, the thin semi-transparent pellicle which covers the surface of the dermis or true skin. It is composed of layers of tessellated or pavement epithelium cells, of a flattened oval or polygonal shape, and about $\frac{1}{1000}$ of an inch in diameter; each cell contains a nucleus with several distinct paler granules. The cells are developed from germs supplied by the basement membrane, nourished by the subjacent vessels, and cast off externally from time to time, to be succeeded by others; when first formed they are spherical, gradually becoming dry and flattened; the deeper layers are more distinctly cellular, while the outer ones are scale-like. The epidermis has no vessels nor nerves, but is pierced by the ducts of the sebaceous and sweat glands, and by the shafts of

the hair or feathers. The rete mucosum seems to be composed of the same microscopic elements as the overlying epidermis, being the principal seat of the pigment cells which give the color to the skin. The epidermis covers the whole exterior of the body, even the front of the eye, and is continuous with the epithelium of the internal mucous membrane; it is thickest in those parts most subjected to friction, as on the heel and the palms of the hands, where it becomes almost as hard as horn. Its use is to protect the sensitive true skin from mechanical injury or the contact of air; in the living body, when abraded, it is speedily replaced; but when it is removed after death, the cutis underneath soon becomes brown and dry. The chemical composition of the thick epidermis of the heel has been found to be very nearly the same as that of the corneous matter of nails, hoofs, horns, and hair. The epidermis is familiarly seen in the occurrence of blisters, constituting the raised portion under which the fluid is effused. The epidermis prevents not only evaporation from the dermis, but also absorption of fluids from without; it is well known to the physician that in introducing medicinal agents into the system by the endermic method, the process is rendered very much more rapid and effectual by previously removing the epidermis by a blister.

EPIGONI (Gr. *ἐπίγονοι*, descendants), the seven sons of the seven Argive heroes who, under command of Adrastus, made an unsuccessful expedition against Thebes, in which all but the leader lost their lives. At the suggestion of Adrastus, the sons made war on Thebes ten years later, to avenge the death of their fathers. Their names are not the same in all the accounts, but as usually given they are Alcæmon, Ægialeus, Diomedes, Promachus, Sthenelus, Thersander, and Enryalus. Under command of Alcæmon, the Argive forces attacked and defeated the Thebans, who lost their leader, Laodamas; while of the Epigoni, Ægialeus, the son of Adrastus, was slain. The Thebans then abandoned their city and sued for peace, but the Argives razed it to the ground. This war of the Epigoni was celebrated in verse, and statues of the seven heroes were erected at Delphi.

EPILEPSY (Gr. *ἐπιληψία*, from *ἐπιλαμβάνειν*, to seize upon), a disease characterized by sudden and temporary seizures of unconsciousness, accompanied by convulsions. This is one of the most horrible diseases that afflict mankind, and it is not surprising that in ignorant ages, in Rome, in Egypt, and elsewhere, epileptics were considered as having excited the anger of the gods, or were worshipped as possessing supernatural powers. This was due to the violence and extraordinary force developed by the muscles in epileptic convulsions; the screaming, the changes in color, the contortions of the face, and the biting of the tongue, followed by a comatose state and afterward by a degree of mental alienation. There are so

many varieties of epilepsy that it is impossible to give a definition of the disease that will apply to them all. In most cases it is characterized by convulsions and loss of consciousness, occurring at longer or shorter intervals, during which the patient is almost in good health. The absence of fever in epileptics serves to distinguish their affection from meningitis and other inflammations accompanied by convulsions. The complete loss of consciousness also distinguishes epilepsy from hysteria. As in most nervous diseases, a hereditary tendency is among the most frequent predisposing causes of epilepsy. Epilepsy often appears in the offspring of persons who have had various other nervous complaints. Bouchet and Cazauviehl say that out of 130 epileptics 30 were descendants of persons who had been either epileptic, insane, paralytic, apoplectic, or hysteric. There is no doubt that women are much more frequently attacked by epilepsy than men. We find by a comparison of the statistics given by several English and French authorities, that the most frequent periods at which epilepsy begins are early infancy and the age of puberty. It often appears also in very old age; Delasiauve remarked that out of 285 epileptics the disease began in 10 when they were from 60 to 80 years old. In fact, no age escapes. As regards climate, nothing very positive has been established, but it seems probable that the disease is more frequent in hot and in very cold than in temperate climates. Herpin and others say that epilepsy is more common in persons of low stature; but even if this be true, Herpin is wrong in considering shortness of stature a predisposing cause of the disease, as in many of the cases on which he grounds his view it is partly the influence of epilepsy that has prevented the development of the body. Various malformations of the body, and especially of the cranium, are certainly among the most frequent predisposing causes. Weak constitutions, as proved by Esquirol and Dr. C. B. Radcliffe, are favorable to the production of epilepsy. Among other predisposing causes are dentition, the first appearance and the cessation of menstruation, onanism, and the abuse of alcoholic drinks. Almost all kinds of diseases may produce epilepsy, but among the principal we must place those affections in which the blood becomes altered or diminished, and organic affections of the membranes of the cerebro-spinal axis and of certain parts of this nervous centre. Another very powerful cause, the influence of which has been demonstrated by Marshall Hall, Kussmaul, Jenner, and Brown-Séquard, is excessive loss of blood. Pregnancy, parturition, and menstruation frequently cause epilepsy. A tumor on a nerve, or any cause of irritation on the trunk of the terminal part of any sensitive nerve, and especially in the skin or mucous membrane, very often produces it. A wound, a burn, worms in the bowels or elsewhere, stone in the bladder or in other places, a foreign

body in the ear, &c., are known to have caused epilepsy. It is quite certain that great mental excitement has originated it in many cases, but it seems probable that the disease was not introduced by those causes, but was only brought by them to manifest itself.—When a complete fit is about to take place, it is usually preceded by some sensation or some change in the mind of the patient. If a sensation precedes the fit, it comes most frequently from some part of the skin, and especially from that of the fingers or toes. This sensation is well known under the name of *aura epileptica*. There is as much variation in the kind and the intensity of the sensation as in its point of starting. Most frequently the aura is a sensation of cold, of burning, or that kind of sensation produced by a draft of cold air on a limited part of the body. Sometimes the aura starts from the eye or the ear, and then a flash of light or some other sensation comes from the retina, or peculiar sounds are heard. Some epileptics become gay, others mournful, when they are about to have a fit; in others the attack is announced by some change in the digestive functions. A complete attack usually begins with an extreme paleness of the face, and at the same time or nearly so there are contractions of several muscles of the face, the eye, and the neck. Observers do not agree as regards the first manifestation of a fit, probably because the seizure does not always begin with the same phenomenon. Not only have we known the first symptom not to be the same in different epileptics, but in the same one we have seen differences in three different attacks. Many physicians think the scream is the first symptom. It often is, but the paleness of the face usually precedes it. Some epileptics do not scream. As soon as these symptoms have appeared, a rigid tetanic or at least tonic spasm takes place in the limbs, and the patient falls. Respiration is suspended, and the face becomes quite injected with black blood, and assumes a hideous aspect both from the spasms of its muscles and the blackish or bluish hue. Sometimes a momentary relaxation is then observed in the limbs; but almost at once clonic convulsions occur everywhere in the trunk, the limbs, the face, and often in the various internal organs, as the bladder, the bowels, and even in the uterus. The mouth then ejects a frothy saliva, often reddened with blood from the bitten tongue. The respiratory muscles, after the first spasms which produce the scream and suffocation, causing a gurgling or hissing sound, become relaxed, and then those employed in inspiration contract, and almost as soon as air has reached the lungs the convulsions cease or notably diminish. Ordinarily the fit is over in a few minutes; but it is not unfrequently the case that after a general relaxation another seizure comes on, and sometimes many occur with very short intermissions. During the whole time the fit lasts the patient is deprived of consciousness, and

when he recovers he remembers nothing that has taken place in the mean time. In some cases the seizure is followed by a prolonged coma, ending sometimes in death. When the patient recovers from a fit, even if it has not been very severe, he usually feels fatigued and suffers from headache. Fortunately he soon falls asleep, and ordinarily is almost as well as usual when he wakes, except that the headache and the fatigue still exist, though much diminished. When many fits have taken place, even at somewhat long intervals, such as several weeks, mental derangement often supervenes, and in this way epilepsy leads to insanity. In some cases the fits recur at regular periods; in others they return with every return of the circumstances which seem to have caused the first, such as menstruation, pregnancy, the influence of certain seasons, &c. There is seldom perfect regularity in the length of the intervals between the fits, and they come every day, every week, every month, &c., at irregular hours. Many patients have very different intervals between their successive fits. Some have many fits a day, others one every six months, or every year. Delasiauve mentions a case in which the number of fits was 2,500 in a month. But the greater the number of fits, the less violent they generally are.—In a complete fit of epilepsy there are two distinct features: 1, the loss of consciousness; 2, the muscular convulsions. Each of these may exist alone. In the case of a seizure consisting only in the loss of consciousness without convulsions, we have the so-called epileptic vertigo, which is a form of epilepsy that frequently exists alone, and also coexists often with the form of the disease in which the attack is complete. In this last case the patient sometimes has a complete seizure, sometimes only an attack of vertigo. Whether vertigo exists alone or coexists with complete attacks, it is very dangerous, not for the life of the patient, but because fits of simple vertigo lead more frequently to insanity than complete fits of epilepsy. The cases of epileptiform convulsions without loss of consciousness are not so frequent as the cases of simple vertigo. They are particularly produced by injuries to the nerves or to the spinal cord.—The nature of epilepsy, the material and dynamical conditions of the parts which are affected in the animal organism, have been greatly illustrated by the researches of modern physiologists and practitioners. Dr. Marshall Hall thought its seat to be chiefly in the medulla oblongata, and that its nature consisted in an increased reflex power, at least in the beginning of the disease, and also that the convulsions were the results of the asphyxia caused by the closure of the larynx (*laryngismus*). This theory is in opposition to several facts. In the first place, although laryngismus almost always exists and certainly concurs in the production of asphyxia, and in so doing generates convulsions, it cannot be considered the cause

of convulsions, as it does not always exist, and as there is one kind of convulsions (the tonic) which precedes the asphyxia. Besides, there are more powerful causes of asphyxia in the condition of the circulation in the brain and the spasm of the muscles of the chest. Then, as regards the increased reflex power, Dr. Hall acknowledges that this power is diminished in persons who have been epileptic for some time. We cannot admit therefore that the disease consists in the increase of this power. Another theory has been proposed by Dr. Brown-Séquard. Guided by experiments on animals, in which he produces epilepsy, he has found that the reflex power is composed of two distinct powers, one of which he calls the reflex force and the other the reflex excitability. He has found that the reflex force may be very much diminished while the reflex excitability is very much increased. This last power is the power of impressibility of the cerebro-spinal axis; in epileptics this impressibility is very much augmented. The slightest excitations may produce reflex actions in them. In the beginning of epilepsy, usually the other reflex power, which is the force manifested in the reflex actions of the cerebro-spinal axis, is increased; but after a time this force diminishes, and in most cases it becomes less, and even much less, than in healthy people. The nature of epilepsy seems to consist in an increase of the impressibility, or in other words of the reflex excitability of certain parts of the cerebro-spinal axis. In most cases of epilepsy these parts are the medulla oblongata and the neighboring parts of the encephalon and of the spinal cord. But the seat is not constant, and may be sometimes limited to the oblong medulla or extended to other parts of the cerebro-spinal axis. Dr. Brown-Séquard has tried to explain the mysterious phenomenon of loss of consciousness. It seemed very strange that at the same time that certain parts of the encephalon were acting with great energy, another part should be completely deprived of action. This, according to him, is very simple. The blood vessels of that part of the brain which is the seat of consciousness and of the mental faculties receive nerves from the medulla oblongata and the spinal cord; these blood vessels when they are excited contract and expel the blood they normally contain, and it is known that all the functions of that part of the brain cease when they do not receive blood. When the excitation that exists in the beginning of a fit acts upon the medulla oblongata and its neighborhood, it produces at the same time the contraction of the blood vessels of that part of the brain which we have mentioned, and a convulsive contraction of the muscles of the face, the eye, the neck, the larynx, &c., all parts receiving nerves from the same source as these blood vessels. In this way the loss of consciousness is explained. The following table from Dr. Brown-Séquard's work on epilepsy shows how the principal phenomena are generated:

CAUSES.

1. Starting of an excitation from a sensitive or an excitable part of the nervous system.
2. Contraction of the blood vessels of the brain proper.
3. Accumulation of blood at the base of the encephalon, due to its expulsion from the brain proper, &c.
4. Spasm of larynx and of expiratory muscles.
5. Asphyxia.
6. Exhaustion of nervous power, except of the part of the nervous centres employed in respiration.
7. Return of respiration.

EFFECTS.

1. Contraction of the blood vessels of the brain proper, and contraction of some muscles, by a reflex action from the central seat of the disease.
2. Loss of consciousness.
3. Spasm of the larynx and of the muscles employed in expiration.
4. Cry and asphyxia.
5. General clonic convulsions.
6. Cessation of the convulsions and return of respiration.
7. Return of consciousness.

—The first thing to be done for an epileptic is to find out the cause of the disease, and to try to get rid of that cause if it still exists. Very often epilepsy depends upon some external cause of irritation which may easily be removed; it is of the greatest importance to discover if there is anywhere such an irritation, and as the patient may not be aware of its existence, it is necessary to look for it everywhere. Of the various modes of treatment, the most powerful are those means of exciting the skin which most readily produce a change in the nutrition of the encephalon and spinal cord. All physicians know what these means are. One of the most efficacious remedies is belladonna. Patients and their families should remember that the rules of hygiene must be followed by epileptics much more closely than by those afflicted with almost any other disease.

EPIMENIDES, a poet and hero of Cnossus, in the island of Crete, flourished in the 7th century B. C. He was a contemporary of the seven wise men of Greece, among whom he is sometimes counted in place of Periander. He was principally occupied with politics and legislation, but of his treatises on these subjects nothing remains. He also wrote a poem on the Argonautic expedition, which is lost. There are many fabulous accounts of his life. He is said to have passed 57 years in profound sleep in a cavern, and to have possessed the marvellous power of separating himself from his body. The Athenians suffering from a plague invoked his aid, and he removed the scourge. His life was prolonged, according to some, to the age of 154, 157, or even 299 years.

ÉPINAL, a town of Lorraine, France, capital of the department of Vosges, 195 m. E. S. E. of Paris; pop. in 1866, 11,870. It lies at the foot of the Vosges mountains, on the railway from Nancy to Belfort, and on the river Moselle, which is here separated by an island into two channels, dividing the town into three parts, connected by bridges. The fortifications built in the 13th century have been destroyed, but the ruins of an old castle remain. The town is well built, and has a Gothic church of the 14th century, a theatre, hospital, communal

college, museum, and public library of 20,000 volumes, tanneries, and manufactories of cutlery, copper, china ware, paper, and oil. It was occupied by the Germans Oct. 11, 1870. Marble of various colors and freestone are quarried in the vicinity.

ÉPINAY, Louise Florence Pétronille de la Live d', a French authoress, born in 1725, died April 17, 1783. She was unhappily married, and while yet young became the mistress of Jean Jacques Rousseau, for whom she built in 1755 his celebrated "Hermitage," and with whom she lived till he became jealous of Grimm, introduced to her by himself. He was also jealous of her friends Diderot and D'Holbach. She lived in seclusion for the last 25 years, but maintained intimate relations with Grimm, and during his absence from France continued, under the guidance of Diderot, his literary correspondence with the sovereigns of Europe. She wrote an educational work entitled *Conversations d'Émilie*, to which a prize was awarded by the French academy in 1783. Her *Memoires et correspondance* (3 vols., Paris, 1818) contains many letters of Rousseau, Diderot, and Grimm, and abounds with information on French society and character in the 18th century.

EPIORNIS, one of the gigantic ostrich-like birds of which the *dinornis* is the type. It was a native of Madagascar, and became extinct probably since the historic period, or at any rate since the appearance of man. The *E. maximus*, judging from the bones of the leg, must have been at least 12 ft. high. The egg measured 13½ in. in length, being as large as 6 ostrich eggs or 144 hen's eggs. This bird, though wingless, may have given rise to the fabled roc; and it must have been seen by primitive man, whose traditions have handed down to eastern nations an exaggerated account of its size.

EPIPHANIUS, Saint, a father of the church, born near Eleutheropolis in Palestine about 310, died at sea in 402 or 403. He was of Jewish parentage, but having become a Christian retired to an Egyptian monastery, where he mastered the Hebrew, Coptic, Syriac, Greek, and Latin languages. At the age of 20 he returned to Palestine, founded a monastery which he governed for 30 years, and wrote several books for the instruction of his monks. In 367 he was made bishop of Salamis in Cyprus, as a reward for the zeal with which he had combated the heresy of Arius and the errors attributed to Origen. After the persecution of Valens he made a journey to Antioch to convert the Apollinarian patriarch Vitalis; thence went to Rome, where he met St. Jerome; and some time afterward proceeded to Jerusalem to warn its bishop against the poison of Origenism. Not succeeding in this, he withdrew to the solitude of Bethlehem, and conferred the order of priesthood on Paulinian, brother of St. Jerome, a violation of the canons which drew on him the censure of the diocesan

bishop. Theophilus of Alexandria, at one time a violent partisan of the Origenist doctrines, had openly accused Epiphanius of heresy; but since the elevation of Chrysostom to the see of Constantinople Theophilus had become a violent opponent of Origen, and involved Epiphanius in his hostility to Chrysostom. By his persuasion a council was assembled in Cyprus, at which the writings of Origen were condemned; and when Theophilus was cited by the emperor to appear in the capital and answer for the burning of the Egyptian monasteries and the murder of the Origenist monks, he sent Epiphanius before him to plead his cause. Epiphanius not only refused to communicate with Chrysostom, but conferred holy orders in one of the city churches, assembled a council of bishops, asked of them to subscribe the decrees of the council of Salamis, and pronounced in the church of the Apostles a sentence of excommunication against the adherents of Origen. Reproved for this by Chrysostom, and unable to obtain the approbation of the emperor, he assumed a milder tone toward his opponent, departed for Cyprus, and died during the voyage. His most important work is his *Panarion*, directed against heresies. His style is uncouth, and his matter thrown together without order or connection. A standard edition of his works is that of Petavius (2 vols. fol., Paris, 1622); his works are also published in Migne's *Patrologia Græca* (Paris, 1856-'61).

EPIPHANY (Gr. ἐπιφάνεια, manifestation; in the Greek liturgy, τὰ ἑσπὰ ἐπιφάνια), the feast of the manifestation of Christ to the gentiles. That this feast was called Epiphany and celebrated in January is attested by Ammianus Marcellinus (xxi. 2), who says Julian kept it at Vienne in Gaul. That it was kept on Jan. 6 is seen in the constitutions of Valens, Theodosius, and Arcadius. Jan. 6 was held to be the day on which the miraculous star led the wise men to Bethlehem, and that on which Christ was baptized in the Jordan, as well as that on which he performed his first public miracle in Cana. St. Paulinus affirms that these three anniversaries were solemnized on this same day in the 4th century. Some African churches commemorated a fourth event, the multiplication of the five loaves by Christ. From the time of the council of Nice (325) this day was set apart throughout the East for the solemn administration of baptism. It was also the custom there, at midnight on the feast of the Epiphany, to fetch water from the springs, which was believed to keep fresh and pure the whole ensuing year. St. Epiphanius says this was done in memory of the water changed into wine at Cana. It was on the Epiphany, in fine, that patriarchs and metropolitans yearly published the "paschal letters" announcing the precise time for the celebration of Easter and Pentecost. Several of them are extant.

EPIPHYTES (Gr. ἐπὶ, upon, and φέρειν, to grow), vegetable parasites found upon man and other animals. Those which grow within

the cavities of the same are called entophytes. As no definite line can be drawn between the two, and as some species belong to both classes, they will be considered together in the present article. It is only of late, and since much attention has been given to the study of cryptogamic botany, that the full nature and importance of the diseases created by many of these growths have been recognized, and the belief in their spontaneous generation been given up. They all belong to the fungi and algæ, but we are not yet sufficiently advanced in our knowledge of cryptogamiæ to attempt any minute classification, or to distinguish between these two orders. Robin and Küchenmeister divide them according to their supposed place in the vegetable kingdom, while Virchow and his followers classify them into those really pathognomonic of disease, and those accidentally occurring in it. For this last arrangement the two following conditions are necessary, viz.: the constant occurrence of the parasite in the disease, and the positive result of inoculation. There are some who say that even this is not enough, and that the fungus may carry the matter of contagion attached to itself, and that this propagates the disease. Schönlein throws out such a hint with regard to animal parasites when he advises our cleaning the itch insect with brush and bath before proceeding to inoculate; and Clemens of Frankfurt asks: "If we were to find constantly in the vaccine matter one and the same fungus, by the transportation of which new variola existed, which should we call the true inoculating matter, the fungus attached to the lymph, or the lymph attached to the spores?" The dwelling places of the cryptogamiæ seem as universal as their growth is simple. Deep under the sea are beds of algæ; within the bowels of the earth they may be found; the air we breathe contains them, and the winds waft them from pole to pole. They form the chief means of resolving dead matter into its original elements, and are present and are gone with a rapidity inconceivable. No wonder that men believed in the spontaneous development of these forms, for their appearance in certain situations seems otherwise inexplicable. The animal parasites live mostly on the living tissues of man or other animals; with the vegetable the reverse is generally the case, and it is those parts already decomposed or diseased which form their chief support. They usually attack, or better succeed in establishing themselves upon, parts not intimately connected with the system and superficial, and therefore less able to resist their influence; or else they attend upon long disease, when the strength of the body is already wasted. This cannot be said however of every species. The character of the soil exercises an important influence over their growth, and may in fact change it entirely. Indeed, we can hardly give any general rules; for some affect an acid nutriment, others alkaline; some

grow upon the outside, where there can be no warmth, others within the heated cavities of the body; some thrive best in light and pure air, others in darkness and carbonic acid; some live in fluid, while others are always found dry. It will be seen then that all these points must be taken into consideration before we attempt to destroy them, and a universal parasite killer is an impossibility, for what is death to one species may be the food of another. The effect of their presence on man is as various as that of the animal parasites, though less dangerous. When the plant has found its favorite and essential elements for reproduction, it grows at once, be it on the outer surface or within the body. At first the growth may be merely superficial; but soon the vegetative structure, the mycelium, begins to seek nourishment in deeper soil, and its filaments penetrate all tissues, wherever the minutest opening is left for its entrance. The spores or mycelium, by acting as a foreign body, may produce absorption in adjacent parts, and thus make way for their progress inward indefinitely. When once the spores gain admission we may see the same result as when we plant the seeds of larger vegetables in the soil. They send forth their sprouts upward and downward, pushing before them whatever resists their progress. But if in addition to the sprouts we should have our seed increasing by self-division, and to an immense extent, what would follow? What wonder then if this process, carried on beneath the less yielding skin, should lead to inflammation and destruction of the parts? The *oidium albicans* may become dangerous in an infant by obstructing the œsophagus or glottis. Impaired vision may be caused by the growth of a fungus within the eye. Atrophy and deformity may result from their presence in the hair and nails. Erosions of the skin, and the inflammation they create, may bring on swelling of glands. Parasites may also prove injurious by irritating the

Pityriasis versicolor.

nervous system, as in *pityriasis versicolor*, or chemically. The vinous fermentation is brought about by the action of a fungus on sugar, by which it is resolved into carbonic acid and alcohol. So too the *sarcina ventriculi* and the *oidium albicans* may cause the acetous and lactic acid fermentations respectively. The very decay of vegetable

parasites may produce putridity in their masses. We see then that vegetable parasites are able to work a multitude of evils upon mankind, but the extent thereof must be in proportion to the condition and size of the organ affected. Although they may in some instances be as troublesome, as dangerous to life even, as their animal relatives, still we are not so much shocked to have our head covered with the spores of the *favus* plant

as with pediculi, though both are marks of uncleanliness, or to know that our stomach is filled with *sarcina*, as to suspect that a frightful *strongylus* lies coiled up in our kidney.—Fungi consist of organs of fructification and a nutritive apparatus. This last is called mycelium, and is made up of threadlike, more or less compacted, elongated cells, which interlace and have no intimate connection. It has such an indefinite form, and differs so little in various species, that from it alone we cannot distinguish them. It varies greatly also according to the condition in which it grows, and whether it be viewed damp or dry. It may exist without bearing fruit, as a tree may remain barren in uncongenial soil; but no species can exist without it, though it may be reduced to a very low development when compared with the fruit-bearing system. Subtile forms of mycelium have the power of penetrating to remote parts, and lying dormant for a long time. The reproductive system consists of spores, which are very small, and in some species are enclosed in receptacles. Their number is literally incalculable, and they increase with immense rapidity. They float freely in water, and their walls are very strong, so that they are well calculated to travel far from their birthplace. Their diminutive size enables them to gain admission into the smallest crevices of the skin or elsewhere, and they are capable of withstanding great extremes of temperature, so that after being kept in a dry state for a long time they are found to possess their entire pristine vitality. The whole plan of their development is still little known, and there is good reason to believe that many of them are imperfectly developed states of other plants, which, if they attained their proper sphere, might present a more complex structure; and when we consider the vast number of forms into which a single germ may develop itself according to the soil in which it happens to grow, their real number may be regarded as comparatively small, and this view is adopted by some eminent dermatologists. Some prey directly upon living tissues, while others destroy them first and induce decomposition, before the proper conditions for their development are attained. The fact of possible inoculation on healthy subjects proves that the presence of some forms at least is the essential cause of the disease connected with them. The fact that mycelium may exist for a long time dormant, till proper conditions are provided for its further development, will explain the sudden appearance of a fungus in various peculiar situations. In the potato disease, for instance, the *botrytis infestans* may show itself in a few hours on the freshly cut surface of a tuber, and on microscopic examination we find mycelium traversing the cells in all directions. They grow within nuts and egg shells, in the cavities of tomatoes when no lesion of the walls exists, and are developed within the brains of birds, in the eye and bladder of man, and on globules of milk within the

udders of cows. Let any room remain undisturbed for any length of time, and then examine the dust which has collected, and multitudes of vegetable spores will be found. We know not but in each breath of air we inhale, each draught we raise to our lips, are lurking germs which, if they find a proper nidus, may make of us a dwelling place.—Among the most important of the vegetable parasites of man is

Oidium albicans.

the *oidium albicans*, which belongs to the same genus as the fungus which has proved such a destructive pest to the vineyards of southern Europe and Madeira, viz., the *oidium Tuckeri*. It forms the disease called aphthæ, which shows itself on the mucous membrane, generally on the tongue of infants, as a soft, white, pasty, slightly elevated patch. On the lips, where it becomes dry, it forms dark brown crusts. Its seat is first the upper surface of the epithelial cells, but soon its filaments penetrate deeply between them, and can no longer be removed by art. It is found also in the nose, windpipe, stomach, and intestine. It may occur in persons of every age, but especially occurs in young children and the old, owing to the liquid form of their food, which allows any accumulation in the mouth to remain undisturbed, and to the long sleep necessary to these ages. It is of frequent occurrence also in the last stages of many diseases, when the mucous membrane is covered with nitrogenous, decomposable matter. According to Küchenmeister, its appearance is due to catarrh of the mucous membrane, which is very common in old age and infancy, and this is without doubt the most frequent predisposing cause. Robin accounts for its presence on the nipples of nurses by the supposed lactic acid reaction produced there, but it is more probable that the disease is transferred thither with the mucus from the child's mouth, and becomes attached by the extension of the mycelium into the epithelium. *Oidium* has

also been found in the nails and on the surface of ulcers. On diptheria this parasite is found to be a constant attendant. Whether its presence causes the inflammation of the throat, or is merely the result of a proper nidus offered it by this specific disease, is not easy to determine. In other cases it seems to give little trouble as a general rule, though in very young children it may produce difficulty of breathing and swallowing. The ulceration which is sometimes found is probably caused by the accompanying catarrh. That it is contagious is shown by its rapid spread in large foundling asylums, and by direct experiment. Its general transference from one mouth to another in such localities is easily understood when we consider their customs—the nipple taken from one child and given to another, feeding various children with the same spoon, and so on. How it appears in sporadic cases also is not difficult to explain, believing as we do that it is an ordinary form, which may grow on many substances, and be transported in the form of its spores in all directions by the air.

—The diseases caused by these parasites may be divided into three groups: those of the alimentary canal, of the scalp, and of the skin. In the first we place the *oidium albicans* already described, and here too belongs the *torula cerevisia*, or yeast plant, its near relative, which is met with occasionally in all the fluid excretions of the body. It forms the ordinary cholera fungus in the vomitus and intestinal discharges of this disease, and is often found in the stomach and attached to the walls of the intestine after death. Its usual presence in fermenting fluids has led to the belief that it was the cause of such change, and we know that when added as yeast it acts as a true ferment; but we do not know but that the peculiar chemical change may offer merely the conditions for its sudden

Merismopadia ventriculi.

appearance and rapid growth. It is another form of the *penicillium glaucum*. Another plant, found most commonly in the fluid of the stomach, is the *merismopadia* (or *sarcina*) *ventriculi*, which has been usually placed among the algæ. It has been found also in the urine, in the intestinal canal, and in the lungs. Its presence in the stomach of man probably causes no symptoms whatever; it has been cultivated

in the stomach of rabbits, and no trouble caused by its presence. It is supposed to be present most frequently in patients suffering from some gastric disease, organic or otherwise; but this is to be accounted for by the fact that such only vomit, and afford material or stimulus for investigation. If we remove from our teeth the yellowish white deposit which collects after the neglect of the tooth brush for several hours, we shall find by microscopic examination, in addition to the

Leptothrix buccalis.

detritus of food, a cryptogamic plant called *leptothrix buccalis*. It is to be found in all persons, however cleanly they may be, and forms a large part of the tartar which collects about the teeth. It grows with great rapidity after eating sugar, and has been seen in the stomach. Of the parasites of the scalp, the *achorion Schaeleinii* is most of all to be dreaded, on account of the deformity and disagreeable odor it gives rise to. It produces the disease known as *favus*, *porri-go favosa*, or *tinea lupinosa*. The spores first settle upon the epidermis of the head, and send forth the mycelium, which penetrates the hair follicles and finally the whole course of the hair itself. The hair becomes pale and lustreless, breaks easily, and is surrounded at its base by concentrically marked yellow and roundish crusts, which smell vilely, and consist of spores and mycelium. From one point this fungus may spread over the whole scalp, producing baldness and scars. Fortunately it is of rare occurrence,

Achorion Schaeleinii.

for a cure is almost impossible. The *trichophyton tonsurans* and *T. sporuloides* also cause baldness when they attack the hair, and the former produces the disease called ringworm, which is so prevalent in asylums for children. The *microsporon Audouini* likewise attacks the hair, and the *M. mentagrophytes* the beard. The only vegetable parasite which is found upon the skin alone is the *M. furfur*, which is the cause of the eruption known as *pityriasis versicolor*. Several of the above mentioned species may take root upon the skin as well as the scalp, but they never form a well marked disease like the latter. Various kinds of cryptogamiae have been observed within the ear, eye, lungs, and nails, but the descriptions of them are very defective, and we hardly know where they belong. It is probable that they are species of fungi which have accidentally found a favorable place for development.—Man is not the only animal infested by the vegetable parasites. Upon the mammalia it is true that few have been observed, but this remains an almost unexplored field. Many birds bear them in their respiratory apparatus, especially the owls, which inhabit damp and shady retreats, frequented by fungi. More curious is it to find within the close-shut cavity of an egg mycelium spreading throughout the contents, and changing them by a peculiar chemical action. This rare phenomenon is produced by the admission of spores within the oviduct before the egg shell is formed. Fish are often taken covered with vegetable growths, which impede their motion through the water as the barnacles act upon ships. A great many species have also been described which are found only upon their gills and in the cellular tissue. In an aquarium, whenever an injury happens to any of its inhabitants, the wounded surface is seen at once to be covered with fungoid growths, which often attain a large size. But it is the insect tribe which suffers most from this cause; for their diminutive size is little able to cope with the parasite, which when once fastened increases at their expense, till it exceeds them in size and destroys them. Flies may be seen at certain seasons struggling through the air with long stems attached, the mycelium of which spreading inward stops their breathing tubes. Certain species of *sphaeria* grow within the larvæ of insects in China and Australia, and completely mummify them, so that they resemble twigs of wood, from which sprout forth branches. The most

Trichophyton tonsurans.

important of all, in an economic point of view, is the *botrytis Bassiana*, which is so destructive to the silkworm. This disease is called muscardine. The spores enter the air tubes of this worm, sending their mycelium through its tissues, and always cause its death. After this the plant pushes its fruit-bearing stems into the outer world, and converts its victim into a mass of mould, from which fresh spores are sent off to spread the disease. Although it only attacks the larvæ, it may by inoculation be cultivated upon the chrysalis and moth. The intestines of insects and worms which live in decayed wood are often found filled with most curious forms of vegetative life, as Dr. Leidy has shown in the case of the *ulmus terrestris*, and the very entozoa which dwell within their intestines are covered with similar growths.—Those who would pursue this subject still further will find much to interest them in the following works: Robin, *Histoire naturelle des végétaux parasites* (2 vols. 8vo, Paris, 1853); Küchenmeister, "Manual of Parasites," translated for the Sydenham society (2 vols. 8vo, London, 1857); Berkeley, "Introduction to Cryptogamic Botany;" and Leidy, "Flora and Fauna within Living Animals," in the "Smithsonian Contributions to Knowledge," vols. v. and vi. (Washington, 1853 and 1854).—The term epiphytes is also applied by botanists to plants which grow upon other vegetables, but which do not derive their nourishment from them. (See AIR PLANTS.)

EPIRUS, next to Thessaly the largest province of ancient Greece, in the S. part of modern Albania, bounded N. by the territory of the Græco-Illyrian tribes, E. by Thessaly, S. by Ætolia, Acarnania, and the Ambracian gulf (now gulf of Arta), and W. by the Ionian sea. The Cerannian mountains separated it from Grecian Illyria; the Pindus, famous in mythology, from Thessaly. Its climate was mild, and its soil less fertile than that of other parts of Greece. The river Acheron received the waters of the Coeytus within its limits, and flowed into the Ionian sea. Epirus was divided into the districts of Chaonia, Molossis, and Thesprotia, named after the most numerous and powerful of its ancient tribes. Its most remarkable places were: Dodona, with the ancient oracle of Jupiter; Canope and Butthrotum, with harbors, chiefly communicating with the port of Brundisium in southern Italy; Ambracia, the capital of King Pyrrhus and his descendants, on the gulf of the same name; and Nicopolis (city of victory), on the same gulf, founded by Octavianus Augustus, in commemoration of the battle of Actium, near the opposite shore. The Epirotes had their share in Grecian fame and history, though the other Greeks did not consider them as belonging to the Hellenic race. Pyrrhus or Neoptolemus, the son of Achilles, is mentioned as king of Epirus after the Trojan war. Olympias, the mother of Alexander the Great, was a princess of this country. But their most dis-

tinguished man was King Pyrrhus (295–272 B. C.), who, in spite of the remonstrances of his chief minister Cineas, destroyed his armies and ruined the state in brilliant campaigns against the Romans and others. Oppressed by Macedonia, the Epirotes were delivered by their ancient enemies the Romans, but proved faithless to their deliverers, supporting against them both Antiochus the Great of Syria and Perseus of Macedonia. They were subdued by Paulus Æmilius (168 B. C.), and cruelly chastised, numerous cities being destroyed, and 150,000 of the inhabitants sold into slavery. Epirus was now a province of Rome, and shared the fate of its eastern dependencies. In 1432 it was conquered by the Turks, from whom it was wrested in 1443 by the famous Scanderbeg, prince of Albania. On his death in 1467 it was reconquered by Mohammed II., and has since been ruled by Turkish pashas, among whom, in the early part of the present century, Ali of Janina distinguished himself by his crimes, talents, and revolts against the authority of the sultan. The insurrection of the Suliotes, in southern Epirus, ended in their own ruin. As volunteers they promoted the independence of Greece without achieving their own. The modern inhabitants are mostly Arnauts.

EPISCOPAL CHURCH, Protestant, an ecclesiastical body in the United States which derives its origin from the church of England. Previous to the American revolution members of the church of England were constantly settling in all parts of the colonies. In Maryland especially they were very numerous, and in 1692 they seem to have constituted a majority of the population sufficiently large to establish their religion as the religion of the colony. In accordance with the prevailing views in the mother church, they held to the necessity of the episcopal office in order to give validity to their ecclesiastical functions. But no bishop was provided for them until after the peace of 1783. Up to that time the Episcopal church in this country was under the oversight of the bishop of London, and American candidates for the ministry were under the necessity of crossing the Atlantic to obtain orders. Efforts had indeed been several times made in the old country to secure an episcopate in the colonies; but these efforts were always defeated by a two-fold influence, one growing out of political complications and animosities, and another a jealousy of episcopacy as associated with lordly titles and vast incomes. It is also affirmed that, especially in New England, a fear that if the colonial dependence of our country on the crown of England should be much longer perpetuated, the establishment of an episcopate like that in England would be inevitable, contributed much to the zeal which characterized the struggle for American independence. In this state of things, as was natural, when the war had actually broken out, some of the church of England people, and more especially those of the northern states, were opposed to

it, and became what were called tories; while others, and particularly those in the southern states, heartily espoused the cause. Washington himself was a church of England man before the revolution, and after the treaty of peace he remained and died in the communion of the Protestant Episcopal church. Mr. Duché, the first chaplain to congress, was a church of England clergyman; and Bishop White of Pennsylvania, the first presiding bishop, was from the start an ardent friend of American independence. As early as August, 1782, a plan had been proposed for a union and organization of "the church of England people" into an independent branch of the church of Christ. No organization, however, was completed till September, 1785; but before this the Episcopalians of Connecticut elected the Rev. Samuel Seabury, D. D., to be their bishop. Dr. Seabury, in consequence of some political obstacle to his getting ordination in England, was consecrated at Aberdeen, Nov. 14, 1784, by three Scottish bishops, Robert Kilgour, Arthur Petrie, and John Skinner. The general convention which met in 1785 made application to the English church for the consecration of bishops for the American church, in order to perpetuate the succession in the Anglican line. For this office Dr. William White of Pennsylvania and Dr. Samuel Provoost of New York had been designated and elected, each respectively by the parishes in the states to which they belonged. They were consecrated in the Lambeth palace chapel, Feb. 4, 1787; and on Sept. 19, 1790, James Madison of Virginia was in like manner consecrated for the American church in Virginia. In 1789 the general convention met, consisting of the then bishops and clerical and lay delegates from each of the states in which any diocesan organization had been effected. At this meeting a constitution and canons for the organization and government of the church as a branch of the catholic church of Christ were adopted. The English prayer book, as revised and adapted to the altered political circumstances of the country, was set forth to be used in all the congregations after Oct. 1, 1790, and it remains unchanged to the present day. In the alterations thus made in the English formularies, it is declared that "this church is far from intending to depart from the church of England in any essential point of doctrine, discipline, or worship, or further than local circumstances require." And it has been held by some, though by no means a majority, that in consequence of this declaration in the preface to the American prayer book, as well as on general principles, the Protestant Episcopal church in the United States retains all the common and canon law of the English church, except in so far as "it may have been deemed inapplicable by its local circumstances," referred to in the preface, or modified or repealed by express legislation. The Protestant Episcopal church in the United States retains from the church of England the Apostles' and

Nicene creeds, the XXXIX. articles, with a slight modification in reference to the connection of the civil government with the church, the catechism, the baptismal offices, and the ordinal. But for the communion office it has rather followed the Scotch than the English church in placing a prayer of consecration and invocation of the Holy Ghost upon the consecrated elements before the administration of them to the communicants, and has even added to the Scottish service a few words making still more unambiguous the eucharistical character of the sacrament. The American church has also stricken out from its form for visiting the sick the formula for private absolution; and in the exhortation preceding the administration of the holy communion, it has omitted the direct reference to and advice in favor of private confession to the priest, and absolution from him. In this revision of the offices Bishops Seabury and White were chiefly instrumental, and Bishop White has left his testimony to the harmony and agreement of views and feelings with which they cooperated in the performance of this task. In regard to the ministry, the theory usually held in the Protestant Episcopal church, like that in the English church, is, that in order to be a valid branch of the church of Christ it must have the Holy Scriptures and the ancient catholic creeds, and the ministry in an unbroken line of succession from the apostles, and in the exercise of lawful jurisdiction; that the Christians of any nation with these conditions constitute a national branch of the church of Christ, totally independent of the jurisdiction and authority of any foreign church or bishop, subject only under Christ to the authority of the universal church in general council assembled; and that as such they have jurisdiction over all their members, and authority in matters of faith to interpret and decide, and in matters of worship and discipline to legislate and ordain such rites and ceremonies as may seem most conducive to edification and godliness, provided they be not contrary to the Holy Scriptures. The Scriptures and the two ancient creeds, as already said, the Protestant Episcopal church has; the ministry also it has obtained, as shown above, from the English church, and preserves in accordance with the ecclesiastical canons and usages which have prevailed from the days of the apostles. Its right to lawful jurisdiction must stand on circumstances and facts peculiarly its own, and found in its history and condition. In the first place it was planted by members of the English church, and in what was then, and continued to be until the American colonies became an independent national sovereignty, a part of the English dominions. The settlers of Jamestown came, in the language of their charter, to "discover and to prosecute effectually the full possession of all such heathen lands as were not actually possessed by any Christian prince or people," and "to establish there both the do-

minion of the British crown and the jurisdiction of the English church, provided always that the statutes devised should be, as near as conveniently might, agreeable to the laws and policy of England, and not against the true Christian faith, as professed in the church of England." They remained a part of the English church so long as the colonies remained a part of the English dominions and dependencies. Holding with the English church that episcopal ordination is necessary to valid jurisdiction and the due administration of the sacraments, the Protestant Episcopal church has been compelled to decline communion with the various Protestant denominations in the country, as none of them have what she regards as a valid episcopate. She does, however, acknowledge the validity of the orders conferred in the Roman Catholic church, but disregards the claim set up by that church to jurisdiction within the United States. This would follow from the fact of her first institution in this country, being planted here not only before the Roman Catholics had made a permanent settlement, but by the English church, and in territory which it is claimed at that time belonged to its jurisdiction. In this state of facts the Protestant Episcopal church consistently regards the Roman Catholic clergy as schismatics, according to the ancient canons, just as is the case in England, where the pope has intruded bishops and priests within the lawful jurisdiction of the established church of the land.—The dioceses of the Protestant Episcopal church formerly corresponded in number and extent with the states. The division of the state dioceses began in 1835, when western New York was made a separate diocese. Since then the dioceses of Pittsburgh (1865), Albany (1868), Central New York (1868), Easton, Md. (1868), Long Island (1868), and Central Pennsylvania (1871) have been established; so that in 1873 the state of New York numbered five, Pennsylvania three, and Maryland two dioceses. The institution of provincial synods has been created for the common interests of the dioceses of one state. The church has missions in Africa, China, Japan, Greece, and Hayti. In 1873 it had 49 organized dioceses, two of which, western Africa and China and Japan, were outside of the United States, and five were missionary dioceses in the territories. In each diocese there is an organized convention, consisting of bishop, clergy, and lay delegates chosen by the people. These conventions meet annually, and provide for all the details of local and specific legislation. The dioceses are organized into a general convention, which meets once in three years. It consists of all the bishops in the actual exercise of episcopal jurisdiction, and of clerical and lay delegates, four of each order chosen from each diocese by its convention. They sit in two houses, and not only is the concurrence of both houses necessary for the passage of any canon or law of the church, but

also a concurrence in case it is asked of each of the three orders, bishops, priests, and laity, in order that any measure may become a law. The number of priests and deacons in 1873 was 2,938; parishes, 2,700; communicants, about 248,000. The income of the principal religious societies during the year 1872 was as follows: domestic committee of missions, \$168,252; foreign committee, \$110,732; American church missionary society, \$53,938; evangelical education society, \$40,008; Protestant Episcopal society for the promotion of evangelical knowledge, \$43,088; the society for the increase of the ministry, \$28,923. The contributions in money for church objects, over and above what was expended in erecting and repairing church edifices and in the support of the parochial clergy, amounted in 1872 to \$6,187,250 89. This sum was devoted mainly to the support of the poor, and in sustaining missions, diocesan, domestic, and foreign. In consequence of its total disconnection from the state and political complications, the Protestant Episcopal church has had a degree of unity, harmony, and peace unknown to the mother church in England; and its increase by a comparison of statistics shows a gain in numbers of 20 or 30 per cent. above the increase in the population of the country since the time of its organization.

EPISCOPIUS, Simon, a Dutch theologian, whose original name was Bischoep, born in Amsterdam in January, 1583, died there, April 4, 1643. He was educated at Leyden, receiving theological instructions from Gomar and Arminius; and his attachment to the Arminian system exposed him to the enmity of the then dominant Calvinistic party. In 1610 he became pastor in Bleiswick near Rotterdam, and in 1611 he was chosen one of six ministers who were to defend Arminianism in a conference appointed by the states general. In 1612 he was invited to fill the chair of theology at Leyden, which Gomar had just quitted. He now became the object of unceasing attacks, was accused of being a Socinian, and of having combined with the Catholics to ruin Protestantism; and the popular animosity, so easily excited in religious causes at that era, became directed against him and his family. In 1618 Episcopus with some of his friends presented himself before the synod of Dort, but they were not allowed to take part in it. The Arminian or Remonstrant clergymen were deposed, and as they refused to renounce for the future the performance of pastoral duties, they were banished by the aid of the government. Episcopus then retired to Antwerp, where he wrote his *Responsio ad duas Patris Waddingii Jesuita Epistolas*, and his celebrated *Confessio Fidei Remonstrantium*. On the renewal of the war between Spain and the Netherlands Episcopus took refuge in France, and resided chiefly at Paris, where he published several works. On the death of Prince Maurice in 1625, when more tolerant principles

ples prevailed in Holland, he returned, preached at Rotterdam, and after 1634 taught theology in the new college established by his friends in Amsterdam. To Arminius belongs the distinction of having founded the sect, but Episcopius was the theologian who first skillfully developed its ideas. Besides his many controversial pieces, the most important of his writings is the *Institutiones Theologiae*. A collection of his works was published by Courcelles (2 vols. fol., Amsterdam, 1650).

EPISTOLÆ OBSCURORUM VIRORUM ("Letters of Obscure Men," the word *obscuri* being intended to mean at the same time ignorant and illiberal persons), a collection of satirical letters in dog Latin, published anonymously in 1515 and 1517, the first part at Hagenau, by the learned publisher Angst, the second at Basel by Froben, though Venice is named on the title page as the place of publication. These letters are conspicuous in the history of the reformation in Germany. At that time John Pfefferkorn, a converted Jew, and Jacob Hoogstraaten were foremost among those in Cologne who endeavored to keep down the light of independent thought developed by the study of the classics. A violent literary feud between them and the liberal thinkers, Reuchlin especially, caused the publication of the *Epistolæ*, a keen and caustic satire on the ignorance and perversity of the clergy. There was much uncertainty in regard to their authorship. Reuchlin, Erasmus, and Ulrich von Hutten were severally supposed to have been the authors. But careful investigation has shown that there was a large number of contributors, including Ulrich von Hutten, Hermann von dem Busche, E. Hess, Peter Eberbach, Rhegius, Sommerfeld, Cæsarius, Pirkheimer, Wolfgang Angst, and Jakob Fuchs, for the first volume; and besides them, Hermann von Nuenar and F. Fischer for the second. The *Epistolæ* were prohibited by the pope in 1517, in consequence of which their popularity increased. The book has been frequently republished. The best editions are those of Frankfurt (1643), London in 12mo (no year given), that edited by Maittaire at London (1710), a new edition by Rotermund (Hamburg, 1827), another by Münch (Leipsic, 1827), and the latest by G. Böcking (Leipsic, 1858), which includes also a third volume, published for the first time in 1689. The satirical form of the *Epistolæ* has on several occasions been imitated by more modern authors. One of these imitations is the *Epistolæ Novæ Obscuro-rum Virorum*, which was published by Prof. Schwetschke (Halle, 1849) as a satire on the German parliament.

EPITHELIUM (Gr. ἐπί, upon, and θηλή, a nipple), the layer of cells lining the internal free surfaces of the body, continuous with the epidermis which covers the external surface of the skin. It arises from cells like the epidermis, which are developed and thrown off in the same manner in both structures; the epi-

thelium, however, serves for totally distinct purposes in the animal economy, as from the soft and moist surfaces covered by its cells are elaborated the various secretions of the body. A continuous layer of its cells may be traced the whole length of the alimentary canal, along the other mucous membranes into the glands and follicles, on the serous and synovial membranes, and the coats of the blood vessels and absorbents. The two principal among the numerous forms of epithelial cells are the tessellated or pavement epithelium, and the columnar epithelium. The tessellated epithelium lines the serous and synovial membranes, the blood vessels, the follicles of most of the cutaneous and mucous glands, and many parts of the mucous membranes; the cells are generally flattened and polygonal, forming by their contact a kind of pavement, and the number of layers is usually small. The columnar epithelium covers the mucous membrane of the alimentary canal, the larger ducts of the glands, the vas deferens, and the urethra; its cells are cylinders, arranged side by side, one end rest-

Cells of
Pavement Epithelium.

Ciliated
Columnar Epithelium.

ing on the basement membrane, the other forming the free surface. These two kinds pass into each other at various points, giving rise to various transition forms, and both are often fringed with delicate filaments or cilia, varying in length from $\frac{1}{100000}$ to $\frac{1}{50000}$ of an inch. (See CILIA.) Ciliated epithelium is found in the cerebral cavities, the ramifications of the bronchi, the air passages, with their nasal, frontal, maxillary, and lachrymal appendages, the posterior fauces, and Eustachian tube; their function seems to be to expel the secretions of these various membranes. The epithelial like the epidermic cells are in a state of continual separation and renewal, more rapid according to the activity of the connected function; the introduction of nutrient matters, the separation of effete substances, the various products of secretion, and the development of the reproductive particles, are effected by the agency of epithelium cells.

EPIZOA (Gr. ἐπί, upon, and ζῷον, an animal), a term used by Owen to signify only a singular class of humbly organized articulate animals, which infest the skin, gills, and eyes of marine animals, but now applied to the most

important of the external parasites of the animal kingdom. They all belong to the branch *articulata*, and to the classes *crustacea*, *arachnida*, and true *insecta*. Beginning with the first of these, we shall find that, like the entozoa, many of them possess limited powers of locomotion, and consequently must pass the whole term of their existence upon the animals they infest; but that as we ascend in the scale of organization, and come to the arachnida, and especially the insecta, there is no longer this dependence upon a fixed position for sustenance and habitation, and that, more independent of the will of others, they only make use of their hosts for accidental nourishment, or compel them to take charge of their young. We shall consider the most important of them in the order of this classification, referring for their anatomy and general description to the articles respectively devoted to these classes.

I. *Crustacea*. The parasitic representatives of this class are confined to the pœcilopodous entomostraca, and are found only upon marine animals, being in fact the substitutes for insects, which cannot live beneath the water. These are subdivided into the *lerneæ* and the *siphonostoma*, which together formed Owen's class of epizoa. The former of these have for a long time puzzled the naturalist on account of their peculiar appearance. Aristotle and Pliny described them; Linnæus placed them among the mollusca; Lamarck removed them to the annelides; and Cuvier arranged them among his intestinal worms. Their forms are very various and fantastic, but they are mostly elongated, with tubular necks of a horny consistency, at the end of which is the mouth armed with sharp implements, by which they attach themselves to the eyes, gills, and flesh of fishes, and suck their blood. The females have long plumose appendages attached posteriorly, which are the ovaries. The males are imperfectly known. The young when first hatched are oval, and possess natatory limbs, by aid of which they seek their proper host, and which, when this object is accomplished, are either transformed by metamorphosis into grasping organs, or are lost. They are often found in great numbers attached to the same fish, and some are even 6 or 8 in. long. They occasionally excite even the largest sword or sun fish to such a state of desperation by the torments they inflict, that it dashes itself upon the beach. They inhabit both fresh and salt water. The *siphonostoma* are of a higher order. They have an oval, flattened body, which is partially protected by a hard shield or carapace, and are provided with three or four pairs of feet armed with sharp claws, by means of which, and sucking disks, they fix themselves to the skin of fishes, and soft parts of crustacea and other aquatic animals. Particular species generally infest particular fishes; and scarcely any fish is free from them. They move with considerable rapidity over the body of the fish, and may leave it for

another host. The *caligi*, of which as many as 40 have been removed from a single codfish, are generally found on weak or diseased fishes on the parietes of the mouth and bronchial cavities, but are unable to suck their blood. Fishermen call them fish lice. The *cyamus* is sometimes found in such numbers upon the whales of the southern ocean as to entirely strip them of their epidermis, and to produce a white color recognized at a considerable distance. None of the crustaceous parasites are ever found on terrestrial animals.

II. *Arachnida*. In this class, nearly allied to the insects, we find a body divided into two principal parts, viz., cephalothorax and abdomen, and provided with four pairs of legs. The abdomen may be subdivided into several segments. The only parasites belonging to it are included in the order *acarina* or mites. These are minute animals, in which the head, thorax, and abdomen are blended in one oval mass. In their immature state they have three pairs of legs; the fourth they acquire later. Before taking up the true mites, we will describe briefly two genera which are found on man, viz.: *linguacula* and *demodex*. The first, sometimes called *pentastomum*, has an elongated, cylindrical body, made up of alternate rings and constrictions, and is about half an inch long. Its head is armed with two large hooks resembling the thorn of a rose bush. It is found enclosed in cartilaginous or calcareous cysts on the surface of the liver in negroes. Another species (*L. ferox*) is now and then met with in *post mortem* examinations encysted on the surface of the liver of whites, but is oftener found in the frontal sinuses of herbivora and dogs. The *demodex folliculorum* bears also the generic names *acarus* and *steazoon*, and is the pimple mite or dweller in the follicles of the human nose. As long ago as the middle of the 17th century it was known that an animal inhabited the comedon, a hard inflamed tubercle which appears on the forehead and skin, especially of young men; but not until 1842 was the subject investigated, by Henle and Simon at the same time. The head of this microscopic parasite is separated from its body by a half-moon-shaped constriction, and is furnished with a double-jointed papilla armed with sharp hooks or saws. The four pairs of legs are short, and consist of three joints which move with difficulty, and are tipped according to some au-

Skin Mite (*Demodex folliculorum*).

thorities with three claws, to others with but one. Several forms are met with owing to difference of age and sex. First we see one whose lizard-like tail is three times the length of the body; the contents of this extremity are dark and granular, consisting of fat globules. In an-

other form the shape is nearly the same, but the whole animal is smaller, and has but three pairs of legs; this is undoubtedly immature. Still a third presents itself with a body like that first described, but with a hinder extremity no longer than the body, and of a conical form, displaying transverse chitinous rings. It seems much more plausible to consider this the male, than to suppose that the tails of the former varieties drop off or shorten. No definite internal structure has yet been made out. Wedl and some other observers think they have made out within the body of the female, and in the field, immature forms without extremities; and if this be true, they are viviparous. They are found generally in the hair follicles of the nose of thick and fat-skinned persons, but may yet be met with on the breast or back, or wherever comedones occur, of which, when present in numbers, they may be the cause, although generally they occasion no trouble. They are usually found with their hinder extremity next the surface, and either close to the hair, or in the canals of the fat glands, upon the secretions of which they live. Their occurrence is very general, and to find them, we have only to squeeze the follicles on the sides of the nose between the finger nails, and to add to their contents beneath the microscope a drop of oil, by which the sebaceous matter is rendered clear. In the dead body they will be found much more deeply seated, as if they had sought warmth by penetrating toward the interior as the surface became cold. The *acar-us* or *sarcoptes scabiei*, or itch insect, will be fully considered in the article ITCH. Still other forms of acari or sarcoptes are sometimes met with on man, transferred to him from the beasts on which they live. Their occurrence is purely accidental, and they are never known to reproduce in such situations. The eruption they cause may be of long continuance, but only because fresh infection takes place by continued contact with the animals affected. The sarcoptes of the various domestic quadrupeds produce upon them the disease known as mange, and are specifically different. The mite of the cat and lion, however, resembles and is probably identical with that of man; so that it is a question whether these creatures got their itch first from man or *vice versa*. The parasite of the horse is large enough to be visible to the naked eye, and its mode of burrowing and of reproduction is nearly the same as that of the *sarcoptes hominis*. It produces a dry scaly appearance of the skin, which is sometimes called "scratches." The cheese and dried-fruit mites may likewise live for a short time on the skin, but cause nothing more than a passing irritation. The family of *ixodes*, or ticks, is also a great plague to man and beast. They live on moss and dry foliage, on sunny hillsides, and in groves and thickets, and never fail to attack grazing cattle and passers by. They bore into the skin with their sharp proboscis armed with horny barbs, and remain

hanging till the body, at first minute and flat, becomes swollen with blood, even to the size of a bean. To tear them away is impossible on account of their recurved barbs, and great caution and patience are necessary; for if violence is used, the head remains behind, and causes inflammation, which may last for months. Generally long and gentle rubbing with some essential oil will make them quit their hold voluntarily. They lay a vast number of eggs, and their multiplication upon oxen and horses is sometimes so great that the animals die of exhaustion. The *gamasida*, beetle lice, are other mites parasitic on birds, reptiles, and insects, and both land and water beetles are often found covered with them.

Bird Mite (*Dermanyssus avium*).

The *dermanyssus avium* abounds in great quantities in bird cages and hen houses, and lives upon the blood of their inhabitants. Numerous cases are on record of their presence in great numbers on persons who frequent such localities, penetrating and living beneath the epidermis. They produce the disease occasionally met with among the wretched and filthy sick of the poor, called *acariasis*. Colonies of mice are often infested with similar parasites. Another mite similar to the *ixodes* is the *leptus autumnalis* of Europe, which, living in grass or grain or upon fruit bushes, gets upon the reapers and passers by, and causes pustules and sores. It is red, whence the name of the disease, *rouget*. A similar parasite is the *bête rouge* of Martinique, which often renders necessary amputation of the sufferer's limbs.

III. *Insecta*. In this division we shall consider the parasitic insects of animals in order commencing with those of the mam-

Red Mite (*Leptus autumnalis*).

malia. The human body serves as a residence for several of these, the best known and most numerous of which are the *pediculidæ*, or lice, which belong to the apterous *ametabola*, or wingless insects without metamorphosis. Four are peculiar to man: *Pediculus capitis*, *P. vestimenti*, *P. tabescentium*, and *phthirius pubis* or *inguinalis*. The head louse is grayish white, and it is supposed to adapt itself to the color of the hair of its host. The males are smaller and less numerous than the

females. The eggs, which are bean-shaped, cling to the hair as soon as laid, probably by means of some glutinous matter secreted by the female. After remaining as nits for 6 days, the young emerge, and at the end of 18 days more are capable of reproducing. Each

Head Louse
(*Pediculus capitis*).

female can deposit 50 eggs in all. The presence of lice is easily detected, for we may see them with the naked eye, and their eggs attached to the ends of the hair cannot escape detection. Even when the old are at work beneath the disgusting disease they create, the females creep forth to deposit the nits upon the fine ends of the hair, perhaps because

too great heat is prejudicial. A mere itching is the first symptom of lice, which leads in simple cases to scratching and slight excoriations of the scalp. Let heads so infested remain for months uncombed and uncared for, and such cases will result as are often seen in European hospitals. A specimen is brought in with hair all matted together in flakes, and looking as if sand and molasses had been poured upon it and dried. The stench is loathsome and sickening. On raising the hair a frightful mass of filth, pus, scabs, and lice is visible. The scalp is found covered with crusts of blood, with open ulcerating sores, and with thick and elevated scabs, from beneath which on pressure pus flows freely. The ears, too, may be converted into a suppurating surface. The *P. vestimenti*, or body louse, is much larger than the preceding species. The head is longer, and its color dirty white. This animal is seldom if ever found on the body, but inhabits the seams and folds of clothing next the skin, where it deposits its eggs. Its bite causes the same itching as that of the *P. capitis*, but the results are different. The scratching brings on papules, which become excoriated, and eczema appears. The clothes adhere to the skin, which brings on exudation, and lastly pustules appear. In some cases constant scratching produces such a hyperæmia that a deposition of pigment follows sufficient to color the whole skin like that of the negro. The *P. tabescentium* of writers has longer antennæ and a larger and more distinctly separated thorax than the two preceding species, and an indistinctly ringed abdomen. It inhabits the skin itself, living in its fold beneath the epidermis, and produces the disease called *phthiriasis*. Leenwenhoeck cultivated a colony on his own leg for a considerable time, and estimated that in eight weeks one female might become the grandmother of 5,000. But some of the best authorities deny the existence of any such

species. The *phthirius pubis* is considerably broader, and has a shorter posterior extremity, than its relatives. Its legs are long, and the hindermost two are armed with immense claws. It is very slow in its motion, and has no eyes. This species, as its name implies, is found most

Phthirius pubis.

frequently on the pubes, but occasionally on the beard, eyebrows, and hair of the breast and axillæ, where it bites deeply into the skin, and lives upon the blood of its host. When present in numbers, these parasites cause an intolerable itching, and may be seen sticking firmly to the surface of the body like black specks of coal. Küchenmeister has found on the heads of an Egyptian mummy and a New Zealand savage nits whose claws differ somewhat in size from those of the ordinary species. Lice are a world-wide pest, and no nation seems free from them. According to Aristotle, they must have been a great plague among the ancients, and Aleman, Sulla, and Philip II. are reported to have died of them. But it is probable that some other parasite, as the mites, was confounded with them.—Rising a step higher among the insects, we come to the *hemimetabola*, or those with an incomplete metamorphosis. In the order *hemiptera* we find the

cimex lectularius or *acanthia lectularia*. The bedbug has a small head, from which project two long three-jointed antennæ. Behind the compound eyes are two small transparent flaps covered with bristles, which are the rudiments of wings. The thorax is

Bedbug (*Cimex lectularius*).

broad and short, the abdominal segment very large, broad, and flat. The eggs are long and cylindrical, and are furnished with a stem, by which in the spring the female fixes them upon objects. It is of a reddish brown, and has a very disagreeable odor, which arises from two

glands that contain a red and granular matter. This pest inhabits the crevices of beds, walls, and furniture, or wherever it can find a convenient place to conceal itself by day. It will lodge in garments also, but always emerges at night to prey upon the blood of man. Its predatory excursions are not wholly confined to the night, for when present in the clothing it bites as well by day. The skin of some individuals seems quite insensible to their bite, while upon others it causes great local irritation. The black point seen in the centre of the blood left in the wound. Sometimes a person is literally almost devoured by these creatures, and the whole body may be covered with the eruption they produce. They are found generally wherever man exists.—The flea (*pulex irritans*) belongs to the holometabolous *aphaniptera*, or hopping *diptera*, which undergo a complete metamorphosis. Its head is short and rounded. The eye is simple. The mouth is provided with two four-jointed palpi, with a long tongue protected above by a short double upper jaw, and a sort of upper double lip or taster, and below by a projecting under jaw. The thorax is provided with two pairs of stigmata, and with three pairs of legs, the first of which are seemingly on the head. The two hindmost are composed of many tarsal joints, which are very long, and furnish the means by which its enormous leaps are taken. They are provided also with long double claws. The posterior segment is covered with ten plates or rings lapping over each other, like shingles on a roof. The color of this parasite is a reddish brown. The male is smaller than the female, and its abdomen is flatter and broader. The eggs are oval, white, and covered with a glutinous matter. In six days after their deposition, either in dust or beneath the nails, small, worm-like, jointed larvæ without feet creep forth from them. In 11 days more they envelope themselves in a thin cocoon, from which at the expiration of 11 days they emerge perfect animals. It is a disputed point whether the males are parasitic; Küchenmeister argues from the structure of their head that they are not. Little need be said here about the habits of this insect, which in some countries, as Italy, Turkey, and Germany, is such an intolerable nuisance. It bites all the time, day and night, and is never satisfied. Its bite, though productive of more itching, does not cause the great irritation the *acanthia* produces. Their horny covering or mail protects them from being crushed except by a wonderful degree of pressure, and their alert senses enable them to avoid the hunter's hand, unless it be skilful and experienced. The *pulex penetrans*, or chigo, jigger, or sand flea, as it is variously

Flea (*Pulex irritans*).

called, is smaller than its relative, and has a proboscis longer than its body. (See CHIRO.) —The larvæ of several forms of insects are occasionally found either in or on some part of man; but as they are an accidental occurrence, they need only be alluded to here. The larvæ of some unknown *æstrus* are sometimes met with beneath the skin. They form pimples from which flows a moisture, while around them the skin is red and painful. Humboldt in his South American travels met Indians with large parts of their exposed bodies thus affected. In the intestinal canal the larvæ of *anthomyia scalaris* and *canicularis* are sometimes found. The *musca vomitoria*, or blue-bottle, sometimes deposits its larvæ in open cavities of the body, as the ear, eye, or wherever else moisture and heat are found. The common flesh fly, *M. carnaria*, and the *M. domestica*, also deposit their eggs at times in hot weather either on open wounds or moist places of the body, and cause the appearance known as "live sores." The larvæ are sometimes deposited in a highly developed condition, so that they become maggots even in a few hours. Quadrupeds also are infested by lice, almost without exception each by one peculiar to itself, though sometimes one species is known to live upon several animals of the same genus. They increase with great rapidity upon such beasts as are kept in dirty stables, seldom cleaned, and poorly cared for, and most frequently are seen upon old horses. They cause irritation, roughness of skin, and loss of hair, in consequence of the disposition of their hosts to bite and rub the affected parts. Fleas abound upon several animals, and are nearly always distinct species. The most frequent and troublesome pests of the herbivora are various *æstri* (*gasterophil*) or breeze flies. The *æstrus* peculiar to the horse, for instance, produces the well known disease called bots. (See BOTS.) Another species, *Æ. ovis*, deposits its eggs in the nostrils of sheep, usually about half a dozen in each individual. The larvæ are soon hatched, and creep by means of their two anterior hooks upward into the frontal and maxillary sinuses. There they remain until ready to undergo metamorphosis, when they fall out, gain their wings, and repeat the process. The larvæ are composed of 12 segments besides the head. Sheep fear these flies greatly, and often huddle together with their heads close to the ground to avoid them. The symptoms of their presence are sneezing and a discharge of glairy mucus from the nostrils, but they seldom do serious injury. The *Æ. bovis* lays its eggs on the backs and sides of oxen and cows. The larvæ, hatched by the heat, penetrate the skin, and by increase of size form tumors as large as pigeon's eggs. They live upon the pus their presence produces. After a time they make a larger aperture, and, creeping out, seek a proper place in which to become chrysalids. The fly when discovered creates a great panic among cattle, and often

drives them frantic to the nearest pool. Birds, too, are nearly all infested by lice, each species generally supporting its own species of parasite, and sometimes more, which lives upon

1. *Cæstrus Bovis*. 2. Larva. 3. Chrysalis.

the feathers and blood of its host.—Insects also, fortunately, are made a dwelling place by other insects, and thus their rapid growth and the consequent destruction of vegetation held in check. *Ichneumon* is the name given to these unnatural parasites. They are small flies with slender bodies, and there are many species known, probably as many as of caterpillars and moths. The female deposits her eggs in the larvæ, pupæ, or eggs of other insects and spiders. When she has found her proper host, a caterpillar for instance, she seizes it, and deposits her egg in the skin behind the head. The larva, soon emerging from the egg, eats its way along within the caterpillar, avoiding those parts essential to life, and by the time the latter has become a chrysalis the former is nearly mature. It lies quiet for a time to undergo metamorphosis, and awaking once again a perfect animal, bores its way out from the cocoon of its murdered host, and flies forth in quest of fresh victims. Thus it is that nature keeps in check its most destructive creatures by means so insignificant and unseen.—See Baird, "British Entomostora" (Ray society, London, 1850); Brant and Katzeburg, *Medicinische Zoologie* (1833); Burmeister, "Manual of Entomology," translated by Shuckard (London, 1836), and *Genera Insectorum* (Berlin, 1833-'46); Newman, "History of Insects" (London, 1839); Westwood on "Insects" (2 vols., London, 1839), and bibliography therein contained; Denny, *Monographia Anoplurorum Britannie* (London, 1842); Siebold, "Anatomy of Invertebrata," translated by Burnett (Boston, 1854); Wedl's *Grundzüge der pathologischen Anatomie* (Vienna, 1854); and Küchenmeister, "Manual of Parasites," translated for the Sydenham society (London, 1857).

EPSOM (Sax. *Ebbsham*), a market town of Surrey, England, on the margin of Banstead downs, 13 m. S. W. of London; pop. in 1871, 6,276. At one time it promised to become a prominent watering place, in consequence of the discovery of medicinal springs impregnated with sulphate of magnesia, from which the celebrated Epsom salt was manufactured. The

springs are no longer visited, but the town has gained another attraction in the great annual races held during the week preceding Whitsuntide on the neighboring downs. They are attended by nearly 100,000 persons of every class of society, and the grand stand on the race course, erected in 1829-'30, will hold 7,500 persons. The chief excitement centres in the race for the Derby stakes, instituted in 1780, which takes place on Wednesday.

EPSOM SALT, the name given in pharmacy to the hydrated sulphate of magnesia, which was obtained as far back as the year 1675 by evaporating the waters of some mineral springs at Epsom, England. Sea water was afterward found to contain it, the brine remaining after the separation of the common salt consisting of the sulphate of magnesia and the chlorides of magnesium and calcium. It was readily obtained by collecting the first crystals which formed, and washing them with a strong solution of the same salt. An excellent quality is manufactured at Baltimore and Philadelphia, from the mineral magnesite, a silicious hydrate of magnesia, which is found in the serpentine of that region. The mineral, reduced to powder, is dissolved in sulphuric acid. The product after drying is calcined in order to decompose the sulphate of iron, and convert it into the peroxide of iron. It is then dissolved in water, and any iron present is precipitated by sulphuret of lime. The crystals of sulphate of magnesia are separated and dissolved again to complete their purification. This salt, and calcined magnesia also, have been prepared from the dolomite or magnesian carbonate of lime, by the process of Mr. William Henry of Manchester. The mineral was calcined, and the lime and magnesia were then converted into hydrates by sprinkling with water; the former was dissolved out by a minimum quantity of hydrochloric acid, and the latter was converted into a sulphate by sulphuric acid.—Epsom salt is also found as a mineral substance, incrusting the walls of caves, in the form of an efflorescence, and also in silky fibres. In the Mammoth cave, Kentucky, loose masses of it adhere to the roof like snow balls, and in many other caves of the western states it is found upon the walls or mixed with the earth upon the floor. It occurs in some of the gypsum quarries near Paris, and in other parts of France; and wherever water becomes charged with gypsum or sulphate of lime, and flows over rocks containing carbonate of magnesia, the sulphate of magnesia is likely to appear from the result of mutual decomposition of the two salts. Hydrated sulphate of magnesia consists of 1 equivalent of magnesia, 20; 1 of sulphuric acid, 40; and 7 of water, 63=123; or magnesia 16.26 per cent., acid 32.52, and water 51.22. It crystallizes in four-sided prisms with reversed dihedral summits, or four-sided pyramids, of hardness 2.25, and specific gravity 1.75. The crystals effloresce slightly in the air, and if

they contain any chloride of magnesium this is shown in their deliquescing. They dissolve in their own weight of water at 60°, and in three fourths their weight of boiling water. Sulphate of soda is sometimes fraudulently mixed with Epsom salt. Its presence may be detected by dissolving 100 grains in water, and precipitating with a boiling solution of carbonate of potash. Unless this precipitate of carbonate of magnesia amounts when dried to 34 grains, sulphate of soda is no doubt present.

—The salt is much used as a cathartic, and, being mild and cooling, is particularly adapted to the treatment of fevers and inflammatory affections. The medium dose is an ounce, and this is said to be deprived of its bitter taste, and rendered quite palatable, by being dissolved in about a pint of water, and boiled a few minutes with 1½ grain of tannic acid or 2 or 3 drams of roasted coffee, strained, and sweetened with sugar. If given in small doses and frequently repeated, its action may be directed to the kidneys rather than to the bowels; and the same happens if for any cause, as for instance intestinal obstruction, it fails to be excreted in the usual manner. The value and activity of many of the celebrated mineral waters of this country and Europe depend upon the Epsom salts or Glauber salts which they contain. The laxative action of sulphate of magnesia is increased by freely diluting it with water. An ounce dissolved in a quart of water will act upon the bowels much more decidedly than the same quantity dissolved in half a pint. This fact serves to explain partly the action of certain natural laxative waters.

EQUATOR (Lat. *æquare*, to make equal), an imaginary circle drawn around any symmetrical solid of revolution (for example, a sphere or an ellipsoid) so that all its points are equally distant from the extremities of the axis of revolution. These extremities are called poles. Thus the earth is an ellipsoid revolving about an axis the extremities of which are called the north and south poles; a circle conceived to be drawn around the earth so that all its points are equally distant from the poles is called a terrestrial equator.—The celestial equator, or as it is often called by astronomers the equinoctial, is a great circle of the celestial sphere, situated in the indefinite extension of the plane of the terrestrial equator. All its points are equally distant from the poles of the celestial sphere. The name takes its origin from the fact that when the sun in his annual course passes through the plane of the celestial equator the days and nights are equal in all parts of the world. This occurs about the 21st of March and the 23d of September in each year, which periods are hence called respectively the vernal and the autumnal equinox; and the points where the plane in which the sun moves intersects the celestial equator are called the equinoctial points. The celestial meridian which passes through these points is called the equinoctial colure.

EQUINOX. See EQUATOR.

EQUITES (plural of the Lat. *equēs*, horseman), or knights, an order of the people in ancient Rome, which in some respects may be compared with the English gentry. Their origin is attributed by Roman historians to the institution of Romulus, who is said to have selected the first 300 out of the three chief divisions of the patricians, and to have divided them into three centuries, named Ramnenses, Titienses, and Luceres, corresponding to similar names of the three patrician tribes. Tarquin the Elder added three new patrician centuries, and Servius Tullus 12 new ones from among the richest plebeians. They formed a regular military body, being obliged to serve on horseback in time of war, and were divided into *turnæ* of 30 men each, subdivided into tens. They were also called *celerēs*, and their chiefs *tribuni celerum*. Politically they seem to have represented an aristocracy of wealth in opposition to the aristocracy of birth, particularly after they became a distinct body of the people by the institutions of Servius Tullius. Under the republic the knights were enrolled by the censors and consuls for a service of five years, being supplied by the state with a large sum for the purchase, equipment, and maintenance of a horse, but with no personal pay. Every dictator, immediately after his appointment by the senate, had to select a commander of the horse, called *magister equitum*. During service they had no votes in the assemblies of the centuries. At the time of the siege of Veii, when the want of cavalry was much felt by the Romans, a new body was added to the ancient knighthood, consisting of a large number of young volunteers who offered to enter the ranks at their own expense. The new knights received regular pay, but had no vote, and no share in many distinctions enjoyed by the old order. Gradually they coalesced into a numerous and wealthy middle class, placed politically and socially between the patricians and plebeians, and were so recognized by a law of Caius Gracchus (123 B. C.). Of the privileges as jurymen which the same laws bestowed upon them, they were deprived by Sulla. At that period they were generally the farmers of the public revenues, under the name of *publicani*, and as such seem to have been despised by the Roman people. Under the empire, owing to the heterogeneous elements of which their increased body was composed, they gradually sank, and in spite of efforts to restore their influence they disappeared from political life under the later emperors. In general the history of the Roman knighthood, as a political institution, is involved in great obscurity.

EQUITY, in a general sense, natural right, but as used in jurisprudence an administration of law with reference to the particular circumstances of a case, in contradistinction to the ordinary method of adjudicating by a rule of general application. This is a theoretical rather than a practical view, for equity as dis-

tinguished from strict law is necessarily administered by uniform rules. A judgment founded upon the particular circumstances of a case, without any reference to principles applying in common to such case and to others, would hardly deserve the name of a judicial decision, but rather would be an arbitrary opinion unregulated by legal analogy. This has never been the nature of equity as administered in any country where laws have been prescribed for the regulation of society. At an early period, it is true, many cases would occur which were not provided for by legislation. In these a discretion must be exercised; but every case when decided becomes a precedent, and thus in time the equitable or exceptional law acquires a systematic form and obligation. Another class of cases is where a positive law is productive of some individual hardship not contemplated in the enacting of the law. Relief may then be afforded by the intervention of an equitable power, whose office is not to abrogate or interfere with the operation of the law according to its real intent, but to afford exemption in cases which were probably not foreseen, and therefore could not have been intended. Again, there may be an omission in a law, whether it be statutory or derived from custom, to provide for cases of non-compliance by reason of casualty or some cause not involving serious fault. Thus where forfeitures or penalties are consequent upon the failure of strict performance of an agreement, there is an obvious distinction between intentional neglect and accidental failure, especially if in the latter case it was by inevitable misfortune. There is here room for equitable relief in the one case without impairing the operation of the law in the other, to which alone it justly applies. It is indeed difficult to distinguish with exact precision the line that divides culpable negligence from excusable omission, or to determine how far actual disability should be a ground of relief from legal obligation. Where no fraud is involved, the obligation of contracts cannot as a general rule be abrogated by a court of equity. Hardship will sometimes occur, and there is a natural impulse to give relief in the individual case; but such leniency often repeated is found to be productive of counterbalancing consequences not at first anticipated, and the necessity of a general rule becomes apparent. The discretionary power of the Roman prætor was at first unrestricted, but it was early brought under certain rules from which he was not allowed to depart. It is true that annually when each prætor went into office he made a formal publication of the rules by which he would be governed in his administration of the laws during his term of office, which might allow the inference that he had an arbitrary liberty to disregard former precedents; but practically it was but the adoption of the edict of his predecessors, with occasional modifications suggested by enlarging experience.—The English equity system was early

dissevered from the ordinary administration of law, and has ever since remained separate. Yet the equitable principles maintained in the court of chancery could have been applied by the common-law courts, and to some extent the latter have been compelled to admit modifications into their practice by analogy to equitable proceedings. Thus the penalty of a bond was formerly held to be the debt, and to be recoverable; yet after the court of chancery gave relief upon the payment of the real debt, which was usually specified in the condition of the bond, the common-law courts gave the same relief at any time before judgment; though if payment of the amount really due was not prior to that time tendered, judgment could be entered for the penalty and enforced by execution for the whole amount. A similar change has also taken place with regard to mortgages. (See MORTGAGE.) Again, the conveyance of lands to uses became a peculiar subject of equity jurisdiction; the use not being recognized at law, but being enforced in chancery. The statute of uses (27 Henry VIII.) was intended to make the use cognizable as the real title in courts of common law, but this effect was defeated by the over-nice scruple of the judges, whereby a limitation of a second use (as when a conveyance was made to A for the use of B, in trust for C) was held not to be within the statute; and the court of chancery again intervened to enforce such second use under the name of a trust, and has ever since retained exclusive jurisdiction of that class of cases in England. Another peculiarity of the English equity system was formerly the right of calling upon the defendant in the action to testify, first by a sworn answer to the complaint, and then by examination upon accounting, and in various other cases, at the election of the complainant. But this distinction has been superseded by the recent statutory provisions in England and most of the United States, by which parties are made competent witnesses in all the courts. (See EVIDENCE, and also CHANCERY.)

EQUITY OF REDEMPTION. See MORTGAGE.

EQUIVALENT, Chemical. When an element enters into chemical combination with another element, it does so in a fixed proportion which may be expressed in numbers. This ratio is termed the combining equivalent, combining proportion, equivalent weight, or simply the equivalent of the element. The term atomic weight is also used synonymously by those who accept the atomic theory. The numbers in the annexed table of equivalents (64) were prepared in 1872 for the use of the students of the school of mines of Columbia college, by Prof. Charles F. Chandler. For convenience of reference both the old and the new equivalents are given. (See ATOMIC THEORY.) The perissads are printed in Italics, and the artiads in Roman. To convert formulas of the old system into the new, double the atoms of the perissads, or halve the atoms of the ar-

tiads, and *vice versa*. Hydrogen is adopted as the unit:

Each element has its own special combining equivalent, and is incapable of uniting with other elements except in this proportion or some multiple of it. The equivalents of compound bodies are represented by the sums of the equivalent numbers of all the elements which enter into their composition. The weights of the equivalents of the elements are ascertained by determining experimentally how much of each is required to replace the others in their combinations with some well known element, the weight of the equivalent of which has been assumed. Thus, the quan-

tity by weight of each element which unites with one equivalent of oxygen to form a protoxide, analogous to water, is usually considered to represent its equivalent. A knowledge of the exact weights of the equivalents is of the first importance to chemists; all calculations regarding the composition of bodies, as in analysis, or of the quantities of materials to be employed in the manufacture of compounds, being based upon them. As the equivalent numbers express nothing but the relative weights in which the elements unite with each other, it is evident that the weight of any one equivalent may be arbitrarily chosen as a standard to which all the others shall be referred; it is essential only that the relation be strictly observed. Tables of equivalents are thus constructed, in which the equivalent weight of each of the elements is attached to its name. Several standards have been selected, but only two have ever been generally used. The equivalent weight of hydrogen, being smaller than that of any other element, was regarded as unity by Dalton, who referred all the other equivalents to it. This system has been generally adopted by the chemists of Great Britain and the United States. It possesses the very great advantage that in it the equivalents are represented by small numbers, many of them without fractions, which are convenient in calculations, and can be easily retained by the memory. Another table, in which the equivalent weight of oxygen is assumed to be 100, has been much used on the continent of Europe. It was proposed by Berzelius, mainly it would seem for the purpose of discountenancing a theory advanced by Prout, that all the equivalent numbers are simple multiples of that of hydrogen; superiority was claimed for it on the ground that as oxygen is the most abundant of all the elements, and as the greater number of bodies studied by chemists are compounds of it, calculations would be simplified if its equivalents were regarded as equal to 100; in which case it is only necessary to add 100, 200, 300, &c., to the equivalent weight of the element with which oxygen is combined, in order to ascertain the equivalent weights of its several oxides. The equivalent of sulphur, a very common element, would also have a simple expression, being equal to 200. But these instances do not at all compensate for the high numbers by which the other equivalents must be represented; numbers which cannot be remembered without great difficulty, and which render even the most common calculations extremely laborious unless logarithms are resorted to. Berzelius, who believed that the equivalent numbers should be regarded as entirely accidental and unconnected with each other, desiring to give them the most accurate expression possible, introduced the custom of attaching to them large decimal fractions; indeed, the power to do this which is afforded by the high numbers of his system has always been claimed as one of its advantages. The

accuracy of thus employing several decimals, in cases where the process by which the result has been obtained is liable to errors of considerable magnitude, was long since pointed out by Erdmann, who called attention to the fact that no greater or lesser number of decimals ought to be given than the experiment justifies. All tables of equivalents heretofore published are more or less defective from neglect of this truth. The equivalent numbers have been thoroughly investigated and revised by Dumas, who has again brought forward and upheld Prout's theory, which, owing to the vigorous opposition of Berzelius, had found but few supporters of late years. Most of the equivalents thus far studied by Dumas are simple multiples of that of hydrogen. To this rule there are, however, several exceptions; among which some are multiples of one half, while others are multiples of one quarter of an equivalent of hydrogen. It is still a subject of discussion whether the equivalents of several of the elements should not be regarded as twice, or that of others as one half of those ordinarily admitted. This change would greatly simplify certain portions of chemical science, and many chemists habitually employ equivalents thus modified.

ÉRARD, Sébastien, a French manufacturer of musical instruments, born in Strasburg, April 5, 1752, died in Passy near Paris, Aug. 3, 1831. He went to Paris at the age of 16, and apprenticed himself to a maker of harpsichords. He soon acquired great reputation for skill, was dismissed by his master from jealousy, had a workshop fitted up for him in the hotel of the duchess de Villeroi, and here in 1780 constructed his first pianoforte, an instrument which, though invented a number of years previously, and in use in Germany and England, was then almost unknown in France. In connection with his brother Jean Baptiste, he soon after established a manufactory of pianofortes in Paris, which gradually became the first in Europe. During the revolutionary period the brothers Érad went to England, and established a manufactory of pianos and harps in London; but in 1796 Sébastien returned to Paris. He constructed the first grand pianos with single action ever made in Paris; in 1808 he much improved the mechanism of the instrument, and in 1823 completed his inventions in this department by the production of his grand piano with repeating movement. Among his many other inventions was his celebrated double-action harp. The celebrity which his instruments gained remains undiminished, and Érad pianos are still unsurpassed for roundness, fulness, and beauty of tone.—He was succeeded in the firm by his nephew JEAN BAPTISTE ORPUE PIERRE, born in Paris in 1794, died in Passy, Aug. 3, 1855. He possessed much of the inventive skill of his uncle; published in 1849 *Notice sur les pianos d'Érad en Espagne, en Italie, en Suisse, en Russie, &c.*; and rebuilt in 1850 the organ constructed by Sébastien

Érad in the Tuileries, which had been destroyed during the revolution of 1830. His death is said to have been caused by grief at the injury done to his estate at Passy by the construction of a railway.

ERASMUS, Desiderius, a Dutch theological and classical scholar and writer, born in Rotterdam, Oct. 28, 1467, died in Basel, July 12, 1536. He was the natural son of Gerard Praet and Margaret, the daughter of a physician of Sevenbergen. He himself received the name of Gerard, but afterward assumed its Latin synonyme Desiderius, the Greek translation of which (Ἑράσμιος) furnished his surname. He was sent first to the school of Gouda, and afterward to the cathedral at Utrecht to become one of the choir boys. At the age of nine he was transferred to the monastic school at Deventer, where he studied the classics. In 1480 both his parents died, and his tutors sent him to the school of Romboldus at Bois-le-Duc, that he might fit himself for the priesthood. For some years he resisted their wishes, and neglected the studies which they arranged for him; but in 1486 he was persuaded by a friend who had just come back from Italy to embrace a life so free from excitement and so favorable to study, and entered the convent of Stein near Gouda. The discipline was not strict. Erasmus was allowed to study other than theological treatises, and his reputation as a classical scholar was soon widely spread. In 1492 he was selected as a companion by the bishop of Cambrai, and was ordained to the priesthood. Erasmus remained with his patron at Cambrai five years, when he went to study at the college of Montaigu in Paris, where he supported himself by taking pupils. His studies were interrupted by serious sickness, which left in him the seeds of a malady from which he suffered all the rest of his life. Among his numerous pupils was a young English nobleman, William Blount, Lord Montjoy, by whom he was promised a pension of 100 crowns if he would take up his residence in England. His two years' stay in that country was made pleasant by the attentions of the nobility and the friendship of the most eminent English scholars. He was presented at court, studied at Cambridge and Oxford, became the associate of More and Colet, and acquired a thorough knowledge of Greek. For several years after his return from England he led an unsettled life, teaching in various cities of France and Holland, translating the ancient classics, investigating the text of the Scriptures, and increasing his acquaintance with the scholars of Europe. In 1505 he again visited England, and received from Cambridge the degree of bachelor in theology. The presents received in England made it possible for him to visit Italy, where his stay lasted nearly three years. At Turin the degree of doctor of theology was conferred upon him. In Venice he resided with the famous printer Aldus Manutius while his collection of "Adages" was in press. In Rome

he was treated with great regard by Pope Julius II., who gave him a dispensation from his monastic vows. Shortly after the accession of Henry VIII. he returned to England. On the journey thither he composed his *Moriæ Encomium*, "Praise of Folly," in many respects his most remarkable work. On his arrival he was received by his friend More, was presented with a living by the archbishop of Canterbury, which he resigned for a pension of £20, and accepted professorships of theology and Greek at Cambridge. In 1514 he returned to the continent at the invitation of the archduke Charles, afterward Charles V., from whom he received the appointment of councillor, with a small salary. This sinecure allowed him to reside where he chose, and he afterward employed his time almost wholly with literary pursuits, correspondence, theological, polemical, and satirical writing, and with editions and translations of many of the less known Greek and Roman classics. With Reuchlin, his only rival as a linguist, he carried on a spirited controversy concerning Greek pronunciation; and the theory which he maintained has until the present century been generally received in the schools of Europe. With Luther his dispute was still sharper. The monk of Wittenberg was at first a warm friend and admirer of the great scholar; but finding that Erasmus was not ready to adopt the extreme tenets of the reformers, he at first expostulated with, then ridiculed, and then denounced his former friend as a time-server, a coward, and a foe to true religion. Erasmus was equally unfriendly to the monastic habits and to the subtleties of the scholastic divinity, and exercised his wit on both of these; but he had no love for theological quarrels, and no wish to draw upon himself unpopularity or persecution. He welcomed the reformation as a movement of free thought, but deprecated its excesses. He disliked all dogmatism, as well as all extravagance in religious rhetoric, and would have the reformers confine themselves to the open vices of the monks and clergy, leaving aside the possible errors in doctrine. His middle course in regard to the reformation brought upon him the censure of zealots in both parties. In 1521 he had taken up his residence in Basel, where he was presently called on to mediate between the Catholic magistrates and the rising Protestant party. His moderate counsels satisfied neither side. The insurrection of February, 1529, completed the overthrow of the authorities; the Roman Catholic religion was definitely prohibited in the city, and all who had opposed the new doctrine were compelled to depart. Though Erasmus had already been condemned as a heretic by the college of the Sorbonne, he could not endure the society of the men in power, and went to Freiburg, where he remained from 1529 to 1535. In vain did the Catholic party try to win him back to full communion, and in vain did the reformers attack him by jest and sar-

casm. He answered the libels of Goldenhauer by pungent rejoinders, he evaded the summons to the diet at Augsburg, and his "Retractions," though promised, were never published. He declined more than one tempting offer, and, while he was not unwilling to accept additions to his scanty income, did not care to obscure his literary fame by the more imposing dignity of a place in the sacred college. In 1535 he returned to Basel, where an attack of gout compelled him to remain, and where he died in the arms of his friends. His last days were cheered by the friendly visits and messages of distinguished men both of the Protestant and of the Catholic party. His death was lamented as a public calamity; a long procession of magistrates and students followed his funeral; and the bequest of his whole property to the aged, the poor, and the orphan seemed to justify the monument which was erected to him in the cathedral at Basel, and which still remains the chief object of interest in that edifice.—Erasmus was small in stature, with light hair and light blue eyes. His portrait by Holbein represents his look as sickly and his face as thin and wrinkled. He was fond of luxurious living, but unable from physical weakness to gratify his appetites. His timidity was excessive. He dreaded to stay in the neighborhood of any contagious disease, and, in spite of his rationalistic tendencies, was frequently haunted by superstitious fears. He had a fine native humor, a keen enjoyment of witty discourse, and an accurate eye for every form of beauty. His taste was as refined as his knowledge was prodigious. He was versed in all the studies of his age; in most of them he excelled. His reading was various, but not desultory. His treatises were finished productions, and their style is always clear, flowing, and eloquent. Erasmus aided the reformation rather as a scholar and critic than as a thinker or reasoner. He exposed the abuses of the convents and the inconsistencies of the scholastic theology, but he produced no new creed and argued in favor of no heretical doctrine. His defence of the right of reason against authority was weak and evasive. But he promoted the study of the Scriptures in their original tongues, affirmed the superior value of early Christian testimonies, and gave an impulse to Biblical and patristic investigations. He was the most gifted and industrious pioneer of modern scholarship.—Erasmus published in 1516 the first printed edition of the Greek Testament from manuscripts, which has been regarded as his greatest work. His complete works, with a biography, were published after his death by Beatus Rhenanus (9 vols. fol., Basel, 1540-'41). Another more complete edition was published at Leyden by Le Clerc (10 vols. fol., 1703-'6). Of the *Colloquia*, his most famous work, a great number of editions have been published; the best is that of Amsterdam (1650). The *Moriæ Encomium* also passed through a great number of editions; it was

translated into German and illustrated by Holbein; the latest edition is that of Havre (1839). His other most important works are the *Copia Verborum*; the *Adagiorum Collectanea*; the treatise *De Libero Arbitrio*, which was answered by Luther; the *Paraclesis*, an exhortation to the study of Christian philosophy; the volume of *Epigrammata*; the *Antibarbarorum Liber*; *Lingua*, a satirical work; an explanation of the Apostles' creed; *Ecclesiastæ, sive de Ratione Concinnandi*, in 4 books; and the immense collection of "Epistles," which show the character of the man. Of his purely classical works, there are editions of Seneca, Suetonius, Aurelius Victor, Ammianus Marcellinus, Eutropius, Quintus Curtius, Cicero *De Officiis*, the "Tusculan Questions," Pliny the Elder, Livy, and Terence, who was his favorite among the Latins, as Plutarch and Lucian were among the Greeks. He also published translations from Xenophon, Isocrates, Euripides, and Libanius, and issued editions of Ptolemy, Demosthenes, and Aristotle. Among his works are also many controversial apologies, Scriptural expositions, and liturgical treatises. The life of Erasmus has been written by Beatus Rhenanus, Melchior Adam, Merula, Scrivenerius, and Gaye, in Latin; by Henke and Müller in German; by Lésèque de Burigny, Bayle, Bullart, and Nisard, in French; and by Jortin, Knight, Charles Butler, and R. B. Drummond (2 vols., London, 1873), in English. See also *Érasme, prédécesseur et initiateur de l'esprit moderne*, by Durand de Laur (2 vols., Paris, 1872).

ERASTUS, Thomas, a Swiss physician and theological polemic, who exchanged his original name of Lieber for its Greek equivalent, born in Baden, Sept. 7, 1524, died in Basel, Dec. 31, 1583. He studied theology and literature in Basel and medicine in Bologna, practised his profession with success, and after being for many years professor of physic at Heidelberg, obtained in 1580 the chair of ethics at Basel. A skilful practitioner, relying on induction from experience rather than on dogmas and theories, he was a formidable opponent of the fancies of Paracelsus and his disciples. His principal theological controversies were in the conferences of Lutheran and reformed divines at Heidelberg and Maulbronn on the Lord's supper, in which he maintained that the reference to the body and blood is figurative. He also had a controversy with Dathenus and Beza concerning the doctrine of excommunication. He held that ecclesiastical censures should extend only to divergences in theological opinion, and not at all to vices and immorality, which were civil offences, and properly punishable only by temporal magistrates. In some of his writings he seems to favor the principle that all ecclesiastical authority is subordinate to the civil power, which is the doctrine commonly recognized as Erastianism. His treatise *De Cæna Domini* (1565) was translated by Shute (London, 1578); his theses on excommunication, written in 1568, were first published in

1589 by Castelvetro, who married his widow. An English translation of his theses was published in 1669, and was reëdited by the Rev. Robert Lee (London, 1845).

ERATH, a N. E. central county of Texas, watered by affluents of the Brazos river; area, 1,000 sq. m.; pop. in 1870, 1,801, of whom 89 were colored. The surface is generally undulating, with some eminences on the S. and N. E. borders. The soil in the valleys is excellent; the uplands are less fertile, but afford good pasturage. Timber of various kinds covers about one third of the surface. The chief productions in 1870 were 9,931 bushels of wheat, 78,109 of Indian corn, 6,533 of oats, and 167 bales of cotton. There were 1,703 horses, 57,609 cattle, 2,312 sheep, and 7,935 swine. Capital, Stephenville.

ERATO (Gr. *Ἐρατώ*, the lovely), one of the nine muses, daughters of Jupiter and Mnemosyne. In the theogony of Hesiod she holds the sixth place among them. She was the protectress of nuptial ceremonies, and the muse of erotic poetry. She disputed with Mercury the honor of having invented the lyre.

ERATOSTHENES, a Greek astronomer, geometer, geographer, poet, and philosopher, born in Cyrene about 276 B. C., died about 196. He was variously named by his contemporaries the "cosmographer," the "measurer of the universe," the "second Plato," and the "pentathlete" or victor in five contests. He had for masters Ariston the philosopher, Lysanias the grammarian, and Callimachus the poet, and he completed his education in Athens. Ptolemy III. invited him to Alexandria and intrusted to his care the renowned library of that city. He is said to have died of voluntary starvation, to which he was led by regret for the loss of his sight. His most important work, the *Γεωγραφικά*, treated of the nature and form of the earth, which he supposed to be a motionless globe, of its magnitude, and of its countries, towns, lakes, rivers, and mountains. He was the founder of geodesy, and was the first to compute the magnitude of the earth by the astronomical method still in use. He is supposed to have suggested the construction of the large *armilla*, or fixed circular instruments, which were long in use in Alexandria. He devised a method for discovering the prime numbers, and resolved the problem of the duplication of the cube. Among his works was one of universal chronology, the fragments of which form the basis of the system adopted by Bunsen in his work on Egypt. He also wrote verses on numerous scientific subjects, a commentary on the astronomical poem of Aratus, and treatises on comedy and on the Homeric poems. A number of other works are attributed to him upon doubtful grounds. Only a few brief fragments of his writings remain; but Strabo and other later writers made great use of his geographical works.

ERBIUM, a metal supposed by Mosander to exist, together with terbium and yttrium, in

the mineral gadolinite of Ytterby in Sweden. Mosander in 1843, while examining the crude yttria obtained from gadolinite according to the method of Berzelius, came to the conclusion that there was a mixture of three earths of different basic power; these he named, in the order of their bases, erbia, terbia, and yttria. Subsequent investigations of different chemists have thrown considerable doubt on the existence of terbium. Bahr and Bunsen separate erbia and yttria by precipitating with oxalic acid, treating with potassium sulphate, converting into nitrates, dissolving, and repeatedly crystallizing; nitrate of erbium is ultimately obtained, containing no appreciable quantity of yttrium. Erbium oxide, prepared by ignition of the nitrate or oxalate, is a faint rose-red powder, and glows with an intense green light at high temperatures, which in the spectroscopic exhibits a continuous spectrum intersected by a number of bright bands. Solutions of erbium salts give an absorption spectrum exhibiting dark bands. The salts of erbium have a rose-red color, and closely resemble in taste and reactions the compounds of yttrium. The atomic weight of erbium is 112.6. The metal has never been isolated.

ERCILLA Y ZUÑIGA, Alonso de, a Spanish poet, born in Madrid, Aug. 7, 1533, died about 1594. He was a scion of an ancient Biscayan family, and after the death of his father, Fortunio Garcia, who was a member of the council of Charles V., he resided at the imperial court, where he was educated as one of the pages of the prince of Asturias, afterward Philip II. He accompanied him on his travels abroad, and went with him to England in 1554, when Philip married Queen Mary. About this time the Araucanians in Chili, whose territory had been invaded by the Spaniards in 1537, rose against them, and many Spanish knights then at the English court volunteered to serve in the war. Ercilla joined this expedition, distinguished himself, and in an interval of the war was involved in a duel during a tournament which was held in Imperial, a city of Araucania, in honor of the accession of Philip II. to the throne. The combatants were both sentenced to death, and it was not without difficulty that Ercilla's sentence was commuted to imprisonment. In 1562 he returned to Spain, in 1570 married María de Bazan, and was employed on different missions by Philip II. His literary fame rests upon *La Araucana*, the most celebrated of Spanish epics. It is in 37 cantos, and celebrates the war with the Araucanians, in which the poet himself was engaged. Ercilla wrote the first and best part of this poem on the battle field, but left it unfinished. The first 15 cantos were published in Madrid in 1569, the second part of the poem in 1578, and the third part in 1590. A continuation of the poem in 33 cantos, written by Osorio, appeared in 1597. The best editions of the *Araucana* are those of Madrid, 1776 and 1828.

ERCKMANN-CHATRIAN, the joint name of two French novelists, who have been collaborators for many years. **ÉMILE ERCKMANN** was born in Pfalzburg, then in the department of Meurthe, Lorraine, May 20, 1822; **ALEXANDRE CHATRIAN**, in Soldatenthal, a forest hamlet near Abreschviller, in the same department, Dec. 18, 1826. The father of the former was a bookseller, that of the latter a glass founder, the descendant of one of the Italian families brought into France by Colbert to introduce the glass manufacture. Erckmann was placed as a boarder in the communal college of Pfalzburg, whence he went in 1842 to Paris to study law. Chatrian, destined by his parents for the business of his ancestors, was sent in 1844 into Belgium, where he soon obtained a good position in the glass works; but, unable to overcome his taste for letters, he returned to Pfalzburg against the wishes of his family, and took the position of an usher in the communal college, where he also had studied for a short time. In 1847 he made the acquaintance of Erckmann, who had been obliged to return to Pfalzburg by illness. From this time their history is common. Erckmann had published previously an *Essai sur le remplacement militaire* (8vo, Paris, 1844), but Chatrian had not yet appeared as a writer. In 1848, after the revolution of February, they went to Paris, Erckmann to continue his legal studies, Chatrian to take a situation in the office of the Eastern railway. In the same year they made their first joint literary venture, furnishing to the *Démocrate du Rhin* a number of short stories, *Le sacrifice d'Abraham*, *Le bourgeois en bouteille*, &c., most of which have since been collected and published in book form. They wrote also for the *Ambigu Comique* a drama entitled *Le chasseur des ruines*, which was accepted on condition of certain changes, which they refused to make. Another play, *L'Alsace* in 1814, was brought out at the Strasburg theatre, but was suppressed by the prefect on its second representation. During the following years they contributed numerous novelettes and serial stories to different publications, exhibiting in their work such a unity of conception and of style that the public remained ignorant of its double origin; but they failed to make any remarkable impression and almost despaired of success. Erckmann continued his studies in a desultory way, giving most of his attention to literature, and did not pass his last legal examination till 1858, Chatrian meanwhile remaining in the railway office. In 1859 the publication of *L'illustre docteur Mathéus* made a change in their fortunes, and their joint names became familiar to the world. Thenceforward they devoted themselves to literature, and many novels, published at regular intervals, exhibit an assiduous and successful collaboration almost unparalleled. Their works strongly reflect the manners and customs of their native region, giving patient and minute photographs of Lotharingian and Alsatian peasant life, and

picturesque descriptions of the scenes familiar to them. The pleasures of Parisian life have never weaned them from the love of their country, and they are said to have built up in the heart of Paris a little Pfalzburg, where they cherish the customs and foster the traditions of their native home. They are strong republicans, and their later writings breathe a spirit which has done much to disabuse the French people of their love for imperialism. Their principal works, besides those already mentioned, are: *Contes fantastiques* (1860); *Contes de la montagne* (1860); *Maître Daniel Rock* (1861); *Contes des bords du Rhin* (1862); *L'invasion, ou le fou Yégo* (1862); *Le joueur de clarinette*, &c. (1863); *Madame Thérèse* (1863); *L'ami Fritz* (1864); *Histoire d'un conserit* de 1813 (1864); *Waterloo* (1865); *Histoire d'un homme du peuple* (1865); *La maison forestière* (1866); *La guerre* (1866); *Le blocus* (1867); *Histoire d'un paysan* (1868); *Le Juif polonais*, a play successfully brought out at the theatre of Cluny (1869); *Le plébiscite* (1872); and *Les deux frères* (1873). Many of these stories have been translated in England and the United States. *Le plébiscite* appeared in England in 1872 under the title "The Story of the Plébiscite, related by one of the 7,500,000 who voted 'Yes,'" and in this country as "A Miller's Story of the War" (1872).

ERDMANN, Johann Eduard, a German philosopher, born at Molmar, Livonia, June 13, 1805. He studied theology at the university of Dorpat, afterward attended the lectures of Schleiermacher and Hegel at Berlin for two years, and returning in 1828 to his native place, became pastor and first preacher there. In 1832 he again went to Berlin, and in 1836 was appointed professor of philosophy at Halle. He has published numerous works on psychology, logic, and metaphysics, dreams, the history of philosophy, &c. The most important is *Versuch einer wissenschaftlichen Darstellung der Geschichte der neuern Philosophie* (3 vols., Leipsic, 1834-'51).

ERDMANN, Otto Linné, a German chemist, born in Dresden, April 11, 1804, died in Leipsic, Oct. 9, 1869. He was professor at the university of Leipsic from 1830 till his death. He was particularly famous as the founder of Erdmann's *Journal für praktische Chemie* (1834), to which he contributed numerous valuable articles. The laboratory established by him in Leipsic was in its day one of the best in Germany, and he was one of the most successful and popular teachers in Europe. He published several books, including *Lehrbuch der Chemie* and *Grundriss der Waarenkunde*, which passed through many editions. He devoted much time to the chemical analysis of indigo and other dyestuffs, and his writings embodying the results of his investigations are not only useful to men of science, but also to merchants.

EREBUS, one of the oldest gods of the Greeks and Romans, son of Chaos and Night. He was changed into a river, into which he had been

precipitated for having assisted the Titans. The term Erebus was frequently applied to a portion of the pagan inferno, a dark and gloomy space beneath the earth, through which the souls of the just passed on their way to enjoy the eternal and delightful life of Elysium.

ERECHTHEUS, or *Erichthonius*, a fabulous hero of Attica, or according to some later writers the name of two persons, one the grandson of the other. Homer describes Erechtheus as an autochthon and king of Athens, and the son of Gæa (Earth); he was educated by Minerva. The one whom Apollodorus mentions under this name was the son of Vulcan and Atthis. Minerva, who reared him secretly, gave him in a chest to Pandrosos and her sisters, who, opening it from curiosity, saw in it a serpent, were seized with madness, and threw themselves down the Acropolis or into the sea. Having expelled Amphictyon, he became king of Attica, established the festival of the Panathenæa, and founded on the Acropolis the temple which after him was called the Erechtheum. By his wife Pasithea he was the father of Pandion. He is said to have decided the dispute between Minerva and Neptune for the possession of Attica in favor of the goddess, and to have introduced the use of chariots with four horses, for which he was set among the stars as Auriga. The myths connected with the life of the second Erechtheus, the son of Pandion by Zenippe, are the Eleusinian war, the sacrifice of one of his daughters, and the suicide of the three others in consequence of a response of the oracle, and his being killed by Jupiter with a flash of lightning at the request of Neptune. The Erechtheus of Diodorus came from Egypt to Athens with grain in time of famine, was made king, and established the Eleusinian festivals. Another Erechtheus, the son of Dardanus and father of Tros in Ilium, is fabled as the richest of mortals, in whose fields grazed 3,000 beautiful mares.

EREGLI, or *Erekli* (anc. *Heraclea*), a seaport town of Asia Minor, in the vilayet of Kastamuni, on the Black sea, 128 m. E. by N. of Constantinople; pop. about 5,000. It has a good harbor, and exports timber, silk, wax, linen, and coal, in exchange for colonial produce, tobacco, and iron. Ship building is carried on to some extent. A few traces are found here of the ancient Heraclea, which was one of the principal towns of Bithynia. Near by is a coal field extending for about 80 m. E. and W. along the shore of the Black sea, and 5 or 6 m. inland. The coal mines are worked under the direction of English engineers, yielding large supplies for steamers and gas works at Constantinople.—There are two other towns of the same name: one in the vilayet and 90 m. E. S. E. of the city of Konieh, in Asiatic, and the other in the vilayet of Edirneh (Adrianople), 55 m. W. of Constantinople, in European Turkey. The latter has a harbor on the sea of Marmora, and is the see of a Greek bishop.

EREMACAUSIS (Gr. *ἐρῆμος*, gentle, and *καῖσις*, combustion), a term applied by Liebig to the gradual oxidation or slow combustion of organic compounds, vegetable and animal, which takes place in the presence of atmospheric oxygen and water. It is allied to fermentation and putrefaction, and is convertible into the latter by limiting the access of air. Eremacausis is accompanied by the evolution of heat, which is generally only slightly manifested in consequence of the slowness of chemical action. When, however, large masses are undergoing decay, sufficient heat may be developed to create active combustion. The temperature most conducive to eremacausis is about 60° F., and never below 32°. Moisture is a necessary condition, perfect dryness always completely arresting the process. Light is often produced by eremacausis in the form of phosphorescence, a phenomenon observed in decaying stumps and trunks of trees, and in animal flesh under favorable conditions. The explanation of this is still a matter of doubt, although modern science offers a solution in the fact that molecular vibrations may be created which are capable of communicating undulations of light unaccompanied by those of heat. The chemistry of eremacausis was carefully studied by Liebig several years ago, and although some of his views have been somewhat modified, they form with the investigations of De Saussure the basis of most of the knowledge we have upon the subject. The decay of wood is the most familiar example of the process, in which the hydrogen of the wood becomes more rapidly oxidized than its carbon, causing the formation of a brown powder called humus or ulmine, a substance which contains a much greater proportion of carbon than woody fibre. The action of oxygen on organic bodies at common temperatures and with free access of air is somewhat analogous to that which obtains when the temperature is raised with limited access of air. It is well known that in the latter case the oxygen unites with other elements than the carbon; also that the oxygen, hydrogen, and whatever nitrogen may be contained in the organic body, separate to a certain extent from the carbon and form new compounds, leaving a portion or nearly the whole of it in a free state, as in the manufacture of charcoal, and the production of coke in the retorts of gas works. In eremacausis, however, there is a union of carbon and oxygen, forming carbonic acid, and also of hydrogen and oxygen, forming water; but the latter process being much more rapid, the remaining portion of the decomposing body becomes richer in carbon, and gradually converted into humus, which substance continues to oxidize, becoming at last completely converted into carbonic acid and water. The nitrogen of the organic body passes into ammonia and into nitrous and nitric acids, and it is supposed that there is also a portion of atmospheric nitrogen absorbed and converted into the same substances. When

nitric acid is formed it combines with the alkaline and earthy constituents of the vegetable juices, forming nitrates. According to Kühlmann, ammonia may also be transformed into nitric acid when the access of air is small; and in this way the nitre in the caves of Zeilan and in the grottoes on the banks of the Seine, and also in cellars, has been accounted for. Fungi are plentifully developed during slow decay, appropriating considerable nitrogen, often more than is contained in the decaying body, but whether directly from the air or through the intervention of other chemical processes, which is probable, is uncertain. Whatever combination takes place between the carbon of the decaying body and the oxygen of the air is also probably not direct, the gas being first absorbed by moisture, and then delivered to the elective affinity of the constituents of the woody fibre. Eremacausis is retarded or completely arrested by all those substances which prevent fermentation or putrefaction, such as creosote, carbolic acid, the mineral acids, and salts of mercury, copper, and other metals. Pasteur, who contends that fermentation and putrefaction are processes carried on by living organisms, adduces a number of experiments which he regards as proving that eremacausis also never takes place except by the influence of certain lower organisms.

ERETRIA, an ancient city of the island of Eubœa, situated a few miles S. E. of Chalcis, whose rival it was in commerce. It was founded prior to the Trojan war, and became rich, powerful, and one of the chief maritime states of Greece. It was early engaged in disputes with the Chalcians, and for having given assistance to the Ionic cities of Asia in their revolt from Persia it was razed to the ground by the Persians in 490 B. C. It was soon rebuilt S. of the old site, and took part in the Peloponnesian war. The philosopher Menedemus, a disciple of Plato, here established a celebrated school of philosophy. The ruins of the city are still visible.

ERFURT, a city of Prussia, in the province of Saxony, capital of an administrative district of the same name, midway between Gotha and Weimar, 145 m. S. W. of Berlin; pop. in 1871, 43,616. It was formerly a city of considerable importance, having at the end of the 16th century nearly 60,000 inhabitants. It is a fortress of the second class, and derives great strategic importance from its situation on the military high road of central Europe. Erfurt contains nine Lutheran and eight Roman Catholic churches, a synagogue, a deaf and dumb asylum, and several schools. The cathedral, a fine Gothic structure, which had suffered much from war, has been well restored within the present century. It contains one of the most massive bells of Germany, weighing 275 cwt. and dated 1447, called Maria Gloriosa, and in popular parlance Grosse Susanna, this having been the name of the bell melted during the fire in 1251. The finest modern churches are the Barfüsserkirche and the Augustinerkirche.

The most interesting religious building of Erfurt is the Augustinian convent, in which Luther lived for several years. It is now called the Martinusstift, and is used as an asylum for orphans and for other charitable purposes. The university, opened in 1392, once the fourth

Cathedral of Erfurt.

in Germany, was suppressed in 1816. The royal academy of popular sciences is remarkable for its extensive library.—Erfurt was ceded to Prussia by the peace of Lunéville in 1801; was taken by the French in 1806; was annexed to Westphalia in 1807; and was transferred by Napoleon to the duke of Saxe-Weimar in 1808. The congress of Erfurt (Sept. 27 to Oct. 14, 1808) was attended by Napoleon, Alexander of Russia, and the kings of Bavaria, Saxony, Württemberg, and Westphalia. In 1813 the town was taken by the Prussians, after a destructive bombardment. From Nov. 24, 1848, to Aug. 4, 1849, it was placed in a state of siege; and in March and April, 1850, the *Unionsparlament* of North Germany, convened by Frederick William IV., was held there in the church of St. Augustine.

ERGOT (Fr. a spur, as of a cock), a protuberance which grows out in a curved form resembling a cock's spur from among the grains of the plants of the *graminaceæ*, or grass tribe, as wheat, barley, and especially rye. As it is most commonly met with in the last, the substance has been known by the name of spurred rye (*secale cornutum*). Some have thought it to be the seed altered by a diseased

growth, caused by the attack of an insect, or by unfavorable circumstances of moisture, heat, &c. De Candolle thought it a fungus occupying the place of the seed, and called it *sclerotium clavus*. But the evidences are now generally regarded as conclusive of its being the grain itself, diseased and deformed by the influence of a parasitic fungus, attached to it from its earliest development. This fungus, distinguishable by the microscope, has been detected in other parts of the plant; and the white dust or *sporidia* on the surface of the ergot will engender the disease in other plants if scattered in the soil at their roots or applied to the grains.—Ergot as collected for medicinal purposes is in solid grains from $\frac{1}{2}$ to $1\frac{1}{2}$ in. long, of cellular structure, the cells containing oily particles. Its aqueous infusion is claret-colored, has an acid reaction, and possesses the peculiar properties of the substance. Ergot contains a volatile alkaloid, secalia, supposed to be identical with propylamia obtained from herring pickle. The fixed oil, which at one time was supposed to partially represent the active principles of ergot, probably owed its properties to an incomplete separation from the other constituents. The so-called ergotine is not a definite chemical principle, but an extract. Ergot is used in medicine to promote the contractions of the uterus either during and after labor, or when independently of pregnancy it is desired to expel any morbid contents. The frequent or routine use of ergot to hasten labor or to expel the placenta is much to be deprecated as productive of danger, in the latter case to the mother, in the former to

1. Ear of Rye with Ergot (Spurred Rye). 2. The Ergot. 3. Diseased Grains of Rye.

both mother and child. Although promoting uterine action, ergot cannot be relied upon for this purpose at all times. Its action has been shown to extend to other organs possessing smooth muscular fibres similar to those of the uterus, and it has accordingly been used to

produce contraction of the blood vessels, as in hæmoptysis, hæmatemesis, aneurism, varix, and congestion of the spinal cord and brain. It is probably by this action upon the blood vessels that the epidemics of ergotism, from the use of diseased grains as food, have occurred in different parts of Europe. Ergotism assumes two forms, spasmodic and gangrenous, and probably requires for its production not only the poisonous action of ergot, but the additional depressing influences of cold, moisture, and insufficient food; a combination which is likely to take place in seasons favorable to the growth of the fungus.—Ergot may be administered in substance, infusion, decoction, fluid extract, or tincture. The dose for a woman in labor is about 20 grains of the substance repeated every 20 minutes till its physiological action is obtained; for other purposes, the dose is from 3 to 10 grains, according to the result sought for. It is apt to deteriorate by keeping, and therefore should be freshly prepared when used. A drop of the fluid extract is intended to represent a grain of the substance. The tincture is a little weaker.

ERIC IX. (according to some historians, VIII.), king of Sweden, called after his death St. Eric, the son of "a good and wealthy yeoman" (in the words of an old Swedish chronicle) named Jedward, died May 18, 1160. His mother was Cecilia, sister of a former king. His wife was Christina, also of royal blood. He was elected to the throne of the Upper Swedes, or as it was called the "royal chair of Upsal," in 1150. With a view to the spread of Christianity he undertook in 1157 a crusade against the heathen of Finland, and by transplanting Swedish colonists thither laid the foundation of the conquest of that country. On his return to Upsal he was attacked by a Danish prince, Magnus Henrikson, and in the battle that followed, at East Aras (modern Upsal), he fell covered with wounds. His virtues and the austerity of his life procured him the reputation of a saint; but he was never canonized. His rule, which at first extended only over Sweden proper (or Upper Sweden), after the death of King Swerker in 1155 also embraced Gothland (Lower Sweden). The effigy of St. Eric is preserved upon the arms of the city of Stockholm; and his remains are in the cathedral of Upsal.

ERIC XIV., king of Sweden, the son and successor of Gustavus Vasa, born Dec. 13, 1533, died Feb. 26, 1577. In youth he was distinguished for his handsome person, his intelligence, and numerous accomplishments; but his passionate and suspicious disposition and immoderate indulgence in pleasure early awakened the apprehensions of his father. Toward his brothers, John, Magnus, and Charles, who had been created dukes of Finland, East Gothland, and Södermanland, he was always jealous and hostile. He succeeded to the throne in 1560, inheriting the good will of his people, a full treasury, and a prosperous

and happy kingdom, and inaugurated his reign by expending what seemed to the Swedes incredible sums on the festivals and pageants attending his coronation. Gustavus shortly before his death had made overtures of marriage to Elizabeth of England in behalf of his son, who, besides keeping alive these negotiations, opened similar ones with Mary queen of Scots, the princess Renée of Lorraine, and the princess of Hesse. But he married Katrina Mansdotter, the daughter of a corporal of his guards, whose beauty attracted his notice as she was selling fruits in the market place of Stockholm. Katrina seems to have been sincerely attached to Eric, and remained true to him amid all his misfortunes. In the beginning of his reign he displayed considerable executive ability, and made several judicious reforms in the civil and ecclesiastical government of the kingdom. He was a patron of science and art, and was the first to introduce the titles of baron and count into Sweden. During nearly his whole reign he was engaged in wars with Denmark and Poland, in the course of which the Swedes acquired from the latter country the Baltic provinces of Livonia and Revel, although at great cost of men and money, whole provinces having been depopulated to supply the army. The animosity of the king toward his brothers increased with years, and finally led to violent measures. John, who had married Catharine, daughter of Sigismund I., king of Poland, without Eric's consent, was besieged in his castle at Abo, and condemned to an imprisonment of four years, and the others were in constant fear of their lives. Assassination became frequent, and under the influence of the royal favorite, Göran Pehrsson, some of the oldest nobility, including the Sture family, were put to death. In the midst of these excesses Eric was attacked by madness, the effect of remorse, and for several days wandered alone in the forest. His brothers John and Charles at length rose in rebellion, and besieged Eric in Stockholm, who after some resistance capitulated, Sept. 30, 1568. He was deposed by the Swedish diet, and after languishing more than eight years in prison was poisoned by order of his brother John, who had succeeded to the throne.

ERICSSON, John, a Swedish engineer and physicist, born in the province of Wermeland in 1803. In 1814 he was appointed a cadet in the engineers, and in 1816 was employed as a leveller on the grand ship canal between the Baltic and the North sea. In 1820 he entered the Swedish army as an ensign, was soon promoted to a lieutenantcy, and was employed in surveys in northern Sweden, attaining the rank of captain. In 1826 he visited England, with the view of introducing his invention of a flame engine; but with mineral fuel it proved a failure. Soon afterward he resigned his commission and devoted himself to mechanical pursuits. Numerous inventions followed, among others the steam boiler on the principle of artificial draft, which was extensively adopt-

ed in London for manufacturing purposes, effecting a great saving of fuel, and dispensing with the huge smoke stacks; and it was adapted to railway locomotion on the Liverpool and Manchester railway in the fall of 1829. The directors had offered a prize for the best locomotive engine, and the lightest and fastest engine exhibited on this occasion was the *Novelty*, which, guided by its inventor Ericsson, started off at the rate of 50 miles an hour. The principle of artificial draft is still retained in all locomotive engines; but a different mode of producing it was accidentally discovered so soon after the display of the *Novelty*, that the original inventor derived no advantage from it. The lightness and compactness of this boiler led to many new applications of steam, and among others to Ericsson's construction of a steam fire engine, which was entirely successful. He constructed a similar engine of greater power for the king of Prussia. For this invention he received the prize medal of the mechanics' institute of New York. In 1833 he reduced to practice his long cherished project of a caloric engine, and submitted the result to the scientific world in London. The invention excited very general interest, lectures were delivered in explanation and illustration of its principle by Dr. Lardner and by Professor Faraday, and it was highly approved by Dr. Andrew Ure and Sir James Phillips. In 1836 he successfully applied the propeller to purposes of navigation; but failing to impress the British admiralty with the value of his invention, in 1839 he came to New York. In 1841 he was employed in the construction of the ship of war *Princeton*, which was the first steamship ever built with the propelling machinery under the water line and out of the reach of shot. The *Princeton* was distinguished for numerous mechanical novelties besides the propeller; among which were a direct-acting steam engine of great simplicity, the sliding telescope chimney, and gun carriages with machinery for checking the recoil of the gun. In the United States division of the London industrial exhibition in 1851, Ericsson exhibited the distance instrument, for measuring distances at sea; the hydrostatic gage for measuring the volume of fluids under pressure; the reciprocating fluid meter for measuring the quantity of water which passes through pipes during definite periods; the alarm barometer; the pyrometer, intended as a standard measure of temperature from the freezing point of water up to the melting point of iron; a rotary fluid meter, the principle of which is the measurement of fluids by the velocity with which they pass through apertures of definite dimensions; and a sea lead, contrived for taking soundings at sea without rounding the vessel to the wind, and independently of the length of the lead line. For these he received the prize medal of the exhibition. In 1852 he brought out a new form of caloric engine in the ship *Ericsson*. It propelled this ship of 2,000 tons from

New York to Alexandria on the Potomac, in very rough weather, in the latter part of February, 1853. On this trip the engines were in operation for 73 hours without being stopped for a moment, and without requiring the slightest adjustment, the consumption of fuel being only five tons in 24 hours; but her speed was not great enough, and the caloric engines were subsequently replaced by steam engines. For several years Ericsson devoted himself to the improvement and perfection of the caloric engine and its application to pumping, printing, hoisting, grinding, sawing, turning light machinery of various kinds, working telegraphic instruments and sewing machines, and propelling boats. (See *CALORIC ENGINE*.) At the commencement of the civil war he entered into contract with the government for the construction of iron war vessels with revolving turrets for the guns, the first practical application of the principle. The first one, the *Monitor*, was completed in 100 days, reached Hampton Roads on the evening of March 8, 1862, and on the following day defeated and blockaded the confederate iron-clad *Merrimack*. Considerable improvements were made by him in the vessels (called monitors from the name of the first one) subsequently built. He has since devoted much attention to the construction of solar engines.—His brother NILS, born Jan. 31, 1802, served in the Swedish army, and from 1858 to 1863 in the navy. He was director of Swedish railways, constructed the canal between the Saima and the gulf of Finland, the docks of Stockholm, and other public works, and was ennobled. He died in Stockholm Sept. 8, 1870.

ERIDANUS, the Greek name of a large northern river which Æschylus confounded with the Rhodanus (Rhône), but which later writers made identical with the Roman Padus, or modern Po, the chief river of North Italy. According to Hesiod and the tragic poets, Phæthon, in a futile attempt to guide the chariot of his father Helios, was struck with a thunderbolt by Jupiter, and fell into this river. His sisters, the Heliadæ, were changed into poplar trees, and their tears into amber, for which this river was chiefly famous. The name was also given to a river of Attica, which flowed into the Ilissus near Athens.

ERIE. I. A W. county of New York, bordering on Lake Erie, bounded N. by the Tonawanda and S. by the Cattaraugus creek; area, about 950 sq. m.; pop. in 1870, 178,699. It is drained and supplied with water power by Buffalo creek and several other small streams. In the N. part the surface is undulating, and the soil well adapted to grain; in the S. it is hilly, and here the land is more suitable for grazing. Iron ore, limestone, brick clay, and water cement are found in considerable quantities. The county is traversed by several railroads, and by the Erie canal, which connects with Niagara river at Black Rock, and has its terminus at Buffalo. The chief produc-

tions in 1870 were 436,193 bushels of wheat, 58,283 of rye, 346,128 of Indian corn, 1,125,339 of oats, 246,551 of barley, 21,804 of buckwheat, 643,932 of potatoes, 143,683 tons of hay, 503,073 lbs. of cheese, 2,149,358 of butter, 158,353 of wool, and 83,015 of hops. There were 16,154 horses, 40,323 milch cows, 17,016 other cattle, 33,324 sheep, and 17,043 swine. There were 1,429 manufactories; capital employed, \$13,043,790; value of products, \$27,446,683. The most important of these were 13 of agricultural implements, 8 of boats, 18 of boots and shoes, 70 of wagons, 87 of clothing, 45 of furniture, 1 of gas, 38 of iron and products of iron, 9 of dressed skins, 23 of machinery, 16 of malt, 8 of soap and candles, 55 of tin, copper, and sheet-iron ware, 19 planing mills, 63 saw mills, 4 distilleries, 42 breweries, 23 tanneries, 14 currying establishments, and 36 flour mills. Capital, Buffalo. **II.** A county of Pennsylvania, forming the N. W. extremity of the state, bordering on New York, Ohio, and Lake Erie; area, 740 sq. m.; pop. in 1870, 65,973. With the exception of a high ridge, several miles from the lake, and running nearly parallel with its shore, the surface is generally rolling and well watered. The soil is clayey, and in the N. part produces good crops of grain. The S. portions are mainly occupied by pasture lands. It is traversed by the Erie and Pittsburgh, the Lake Shore, the Philadelphia and Erie, the Oil Creek and Alleghany River, the Atlantic and Great Western, and the Buffalo, Corry, and Pittsburgh railroads; also by the Beaver and Erie canal. The chief productions in 1870 were 308,315 bushels of wheat, 531,584 of Indian corn, 743,106 of oats, 100,014 of barley, 27,464 of buckwheat, 415,989 of potatoes, 90,551 tons of hay, 165,739 lbs. of cheese, 1,896,701 of butter, and 170,825 of wool. There were 11,117 horses, 20,140 milch cows, 16,781 other cattle, 40,746 sheep, and 11,364 swine. There were 928 manufactories, with an aggregate capital of \$5,717,993. The principal establishments were 19 flour mills, 15 iron works, 20 tanneries, 9 currying establishments, 14 breweries, 14 planing mills, 56 saw mills, 9 manufactories of agricultural implements, 6 of boots and shoes, 15 of bricks, 45 of carriages and wagons, 1 of cars, 5 of rectified coal oil, 20 of barrels and casks, 9 of machinery, 9 of pumps, 12 of sashes, doors, and blinds, 29 of tin, copper, and sheet-iron ware, 3 of wooden ware, 1 of wood work, and 8 of woollen goods. Capital, Erie. **III.** A N. county of Ohio, bordering on Lake Erie and Sandusky bay; area, 250 sq. m.; pop. in 1870, 28,188. It is drained by Huron and Vermilion rivers. Near Huron river are several ancient mounds and enclosures, and at Sandusky are extensive quarries of valuable limestone. The surface is generally level, the soil alluvial and exceedingly fertile. It is traversed by the Cincinnati, Sandusky, and Cleveland, the Sandusky, Mansfield, and Newark, and its Huron branch, and the Lake Shore and Michi-

gan Southern railroads. The chief productions in 1870 were 239,874 bushels of wheat, 550,026 of Indian corn, 307,089 of oats, 22,865 of barley, 259,960 of potatoes, 19,523 tons of hay, 339,958 lbs. of butter, 169,905 of wool, and 54,701 gallons of wine. There were 4,813 horses, 4,700 milch cows, 3,527 other cattle, 39,751 sheep, and 7,863 swine; 2 manufactories of cars, 20 of barrels and casks, 2 of cutlery and edge tools, 13 of cured fish, 2 of hubs and wagon material, 2 of iron castings, 5 of machinery, 1 of printing paper, 3 of sashes, doors, and blinds, 10 of tin ware, 7 of cigars, 4 establishments for turning and carving wood, 15 for ship building, 2 for pork packing, 7 saw mills, 6 flour mills, 4 breweries, and 33 manufactories of wine. Capital, Sandusky.

ERIE, a city, port of entry, and the seat of justice of Erie co., Pennsylvania, situated on Lake Erie, nearly midway between Buffalo and Cleveland, 117 m. N. of Pittsburgh; pop. in 1840, 3,412; in 1850, 5,858; in 1860, 9,419; in 1870, 19,646, of whom 6,928 were foreigners. It stands upon an elevated bluff commanding a fine view of the lake. The streets are broad, and laid out at right angles with each other. State street is the principal business thoroughfare. The city contains several parks. Among the public buildings are the post office, the custom house, and the opera house, recently constructed. The union depot, of brick, in the Romanesque style, is 480 ft. long, 88 ft. wide, and two stories high, and is surmounted by a cupola 40 ft. high. The Erie cemetery, occupying a plot of 75 acres on Chestnut street, near the city limits, is beautifully laid out with drives and walks, and is adorned with trees, flowers, and shrubbery. The Erie Extension canal (abandoned) connected the city with the Ohio river, and the Lake Shore and Michigan Southern, the Philadelphia and Erie, and the Erie and Pittsburgh railroads afford communication with Buffalo, Philadelphia, Pittsburgh, and the west. The harbor, which has been artificially improved, is $3\frac{1}{2}$ m. long, over 1 m. wide, and from 9 to 25 ft. deep, and is protected by Presque Isle, formerly a peninsula, lying in front of the city. At the entrance are two lighthouses. There are several large docks, some of which are furnished with railroad tracks, so that the transfer of merchandise takes place directly between the vessels and the cars. For the year ending June 30, 1872, there were entered in the coastwise trade 429 steamers of 370,231 tons, and 796 sailing vessels of 267,466 tons; cleared, 427 steamers of 363,105 tons, and 867 sailing vessels of 286,960 tons; entered from Canadian ports, 59 American vessels of 16,137 tons, and 52 Canadian vessels of 8,604 tons; cleared for Canadian ports, 16 American vessels of 2,809 tons, and 41 Canadian vessels of 6,739 tons; value of imports from Canada, \$131,500; exports to Canada, \$48,823. There were belonging to the port 88 vessels of 16,669 tons, of which 23 of 9,376 tons were steamers, 19 of 5,231 tons

sailing vessels, and the rest canal boats and barges; built during the year, 5 vessels of 3,760 tons. The principal articles of shipment are lumber, coal, iron ore, and petroleum. The leading manufactures are of iron, embracing stoves, steam engines, machinery, car wheels, and car work, besides which there are several manufactories of bricks, leather, organs, pumps, furniture, and other wood work, a brass foundry, six petroleum refineries, five beer breweries, two ale breweries, three malting establishments, &c. There are four national banks, with an aggregate capital of \$850,000, a safe deposit and trust company, three savings banks, and four insurance companies. Erie is divided into six wards, and is governed by a mayor, and a select council of two members and a common council of three members from each ward. It is lighted with gas, and is supplied from the lake with water, which is forced by powerful engines to the top of a tower 200 ft. high, whence it is distributed through the mains. In 1872 there were 49 public schools, viz., 1 high, 16 grammar, 30 primary, and 2 evening, having 53 teachers and an average attendance of 2,154 pupils. St. Benedict's female academy (Roman Catholic) had 17 teachers and 60 pupils. The young men's Christian association has a library of 4,710 volumes. There are one daily and six weekly (two German) newspapers, an academy, marine hospital, city hospital, jail, orphan asylum, and 29 churches.—The French had a fort on the site of Erie, known as Fort de la Presqu'isle, about 1749. The town was laid out in 1795. A portion of it was incorporated as a borough in 1805, and in 1851 a city charter was granted. The fleet of Com. Perry during the war of 1812–15 was built and equipped here.

ERIE, Lake, the most southern of the five great lakes of the northern United States and of Canada, and the lowest of the chain, except Lake Ontario, which lies below it to the north-east. It is bounded N. by the province of Ontario, Canada, S. E. and S. by New York, Pennsylvania, and Ohio, and W. by Michigan, and lies between lat. $41^{\circ} 25'$ and $42^{\circ} 55'$ N., and lon. $78^{\circ} 55'$ and $83^{\circ} 34'$ W. Both the lakes named lie nearly in the extension of the line of the river St. Lawrence, the outlet of all these bodies of fresh water. The mean length of Lake Erie is about 240 m.; mean breadth, 40 m.; circumference, 660 m.; elevation above the level of the sea, 565 ft.; area, 9,600 sq. m. Its surface is 333 ft. above that of Lake Ontario, this great descent being made in the Niagara river, which connects the two lakes. The form of the lake is elliptical, its maximum length exceeding the mean by only about 15 m., and the breadth varying from 30 to 60 m. Its western extremity receives from the north the waters of the upper lakes, discharged by the Detroit river. At this extremity are many islands clustered together, the largest one about 14 m. in circumference. They are well wooded, with a fertile soil de-

rived from the limestone rocks of which they are composed, and to some extent they are under cultivation. The peculiar features of Lake Erie are its shallowness and the clayey nature of its shores, the depth, except near its lower end, rarely exceeding 120 ft. The United States engineers found three divisions in the floor of the lake, of increasing depth toward the outlet. The upper portion, above Point Pelee island, has a level bottom with an average depth of 30 ft. The middle portion takes in the principal part of the lake, extending to Long Point. The bottom is here level also, and from 60 to 70 ft. below the surface. Below Long Point the depth varies from 60 to 240 ft. Its bottom is a light clayey sediment, which rapidly accumulates from the wearing away of the strata that compose its shores. Along the coast the loosely aggregated products of the disintegrated strata are frequently seen forming high cliffs, which extend back into elevated plateaus. The rivers cut deep channels through these, discharging the excavated matters into the lake. The underground watercourses penetrate through the base of the cliffs and undermine them, and the waves aid to break them down. Slides are of frequent occurrence. The water takes up the earthy materials, and is rendered turbid by them a long way out from the land. This may be seen on both sides of the lake; and about Cleveland in Ohio the wearing back of the coast line has been particularly remarked. For 40 m., extending E. to Fairport, the shores are of this character, the stratified clays and sand forming a terrace, the height of which at Cleveland is 103 ft. above the water. Owing to the shallowness of the lake, it is readily disturbed by the wind; and for this reason, and for its paucity of good harbors, it has the reputation of being the most dangerous to navigate of any of the great lakes. Long continued storms, with the wind setting from one extremity of the lake toward the other, produce disastrous effects upon the land to leeward by the piling up of the waters. From this cause the city of Buffalo at the foot of the lake has suffered serious damage in its lower portions. The return of the waters after the storm is in some instances so rapid, when driven along by a wind setting in the same direction, that powerful currents are produced. In October, 1833, a current thus caused burst a passage through the peninsula on the N. coast called Long Point, and excavated a channel more than 9 ft. deep and 900 ft. wide. The natural harbors around the lake are few, and these have required artificial improvement. They are generally at the mouths of the small rivers which flow into the lake, the channels of which are carried far out by piers, constructed on one or both sides. Erie in Pennsylvania has a large natural harbor, formerly known as that of Presque Isle, which has been improved. The best harbor between it and Buffalo is Dunkirk. The other principal harbors on the S. side are those of

Cleveland, Sandusky, and Toledo. On the N. shore there is a harbor called Port Maitland, at the entrance of Grand river near the E. end of the lake, and this river is navigable by small vessels for some distance. Other harbors on the same side are Ports Dover, Burwell, and Stanley. Lake Erie drains but a narrow margin of country around it, and receives no rivers of importance. The Maumee is the largest on the American side, entering the lake at its S. W. extremity, its course being nearly on the extended line of the river St. Lawrence and the two lakes Ontario and Erie. Sandusky river, further E. in Ohio, rises about 60 m. S. of the lake; but more to the east the rise of the surface to the north reaches nearly to the lake shore, determining the drainage in the opposite direction, which is that of the general slope of the strata. The lake was early navigated by sailing vessels built upon its shores, and as many as seven steamers were running upon it in 1830. It is usually closed by ice in the early part of December, and continues more or less frozen over till March or April. In the season of navigation an immense amount of transportation is done upon it, and its commerce is of great value. The communication with Lake Ontario is through the Welland canal, constructed across the Canadian peninsula. On the American side are six customs districts, viz.: Buffalo Creek and Dunkirk, N. Y.; Erie, Pa.; and Cuyahoga, Sandusky, and Miami, Ohio. The value of the imports from Canada for the year ending June 30, 1872, was \$3,429,722; exports to Canada, \$3,945,588; entered from Canadian ports, 1,284 American vessels of 579,352 tons, and 986 Canadian vessels of 157,889 tons; cleared for Canadian ports, 1,168 American vessels of 533,845 tons, and 1,010 Canadian vessels of 162,509 tons; entered in the coastwise trade, 3,340 steamers of 2,132,391 tons, and 8,229 sailing vessels of 1,934,972 tons; cleared, 3,377 steamers of 2,147,819 tons, and 8,397 sailing vessels of 1,976,408 tons. There were registered, enrolled, and licensed in these districts 1,576 vessels of 257,377 tons, viz.: 241 steamers of 79,054 tons, 429 sailing vessels of 98,295 tons, 886 canal boats of 75,971 tons, and 20 barges of 4,057 tons; built during the year, 88 vessels of 18,445 tons, viz.: 29 steamers of 8,914 tons, 15 sailing vessels of 4,256 tons, 38 canal boats of 3,829 tons, and 6 barges of 1,446 tons. The fisheries of Lake Erie are of little importance compared with those of the upper lakes, where the same kinds of fish are more abundant and of better quality. The chief varieties taken are lake trout and whitefish; other varieties are sturgeon, sisquit, muskelonge, black bass, white bass, Oswego bass, and several species of pike.

ERIE, Lake, Battle of, an important naval engagement in the war of 1812 between the United States and Great Britain, fought near the W. extremity of the lake, Sept. 10, 1813. The naval supremacy on the lakes was a matter of much moment, and the American forces on

Lake Erie were intrusted to Lieut. Oliver Hazard Perry, who equipped a squadron of nine sail at Erie on Presque Isle bay, and, although blockaded by the British fleet under Capt. Barclay, succeeded in getting his squadron out of port Aug. 12, 1813. On the 28th Perry was made master commandant, and on Sept. 10 lay in Put-in-bay, near Sandusky, when he discovered the British squadron in the offing, and went out to meet it. It consisted of six vessels, viz.: the ships *Detroit* and *Queen Charlotte*, the schooner *Lady Prevost*, the brig *Hunter*, and the smaller vessels *Chippeway* and *Little Belt*, in all mounting 63 guns, with 502 officers and men. Perry had nine vessels, viz.: the brigs *Lawrence*, *Niagara*, and *Caledonia*, and the *Scorpion*, *Ariel*, *Somers*, *Porcupine*, *Tigress*, and *Trippe*, with 54 guns and 490 officers and men. The Americans had some advantage in able seamen, Barclay's vessels being chiefly manned by Canadian watermen and soldiers. Only the *Lawrence* and *Niagara*, however, of the American squadron, were regular vessels of war, the others having been built for trading. Their guns were of heavier calibre than those of the English, but of shorter range. This enabled the British to open the battle with advantage. They concentrated their greater number of long-range guns on the *Lawrence*, Perry's flag ship, and by half past two o'clock, out of her 101 officers and men, only 18 were not disabled, and all her guns were rendered ineffective. In this desperate condition Perry left the *Lawrence* in command of Lieut. Yarnall, and shifted his flag to the *Niagara*, which lay half a mile to windward, crossing in his boat under a heavy fire. Lieut. Elliott of the *Niagara*, leaving his own ship, took command of the *Somers*, and brought up the smaller vessels of the fleet, which had as yet been little in the action. All together now bore down upon the enemy, and passing through his line, opened a raking cross fire, which in seven minutes compelled the surrender of the British flag ship *Detroit*, and of the *Queen Charlotte*, *Lady Prevost*, and *Hunter*. The *Chippeway* and *Little Belt* endeavored to escape, but were overtaken by the *Scorpion* and *Trippe* and surrendered to them about an hour later. When Perry saw that victory was secure he wrote with a pencil on the back of an old letter, resting it on his navy cap, the despatch to Gen. Harrison: "We have met the enemy and they are ours—two ships, two brigs, one schooner, and one sloop." The combat had lasted about three hours, with a loss on either side of about 130 in killed and wounded, Barclay himself among the latter. This victory completely established the American supremacy on the lake, and enabled the naval force to coöperate with Gen. Harrison by transporting troops and stores, so that *Detroit* was evacuated by the British, and Michigan released from British occupation and Indian warfare. Congress bestowed gold medals upon Perry and Elliott, and other rewards upon the officers

and men generally. The remains of the officers killed were buried at Put-in Bay island, on the anniversary of the battle in 1858, when the corner stone of a monument was laid.

ERIE CANAL. See CANAL.

ERIES (properly *Eriké*), a tribe of Indians of the same family as the Hurons, Iroquois, and Susquehannas. They seem in early times to have dwelt near the Niagara river and Lake Erie, but were driven inland by enemies in the west. They took no part in the war between the Iroquois and Hurons, but after the overthrow of the latter were attacked by the former about 1653. Being brave and expert bowmen and able to raise 2,000 warriors, they took up arms, invaded the Seneca country, and gained several victories, so that the Iroquois cantons sought the aid of the French and agreed to receive missionaries. An Iroquois army of 1,800 men in 1656 invaded the Erie territory, and, though the Eries sought to make peace, attacked one of their palisaded forts, to which they had fled. After a desperate resistance the fort fell, most of the Eries were put to death, and the remnant of the tribe was incorporated with the Senecas. Their locality at this time cannot be positively identified; it abounded in wild cats, whence they were called Chats by the French; and it was near oil springs. One of their towns was called Kentaienton.

ERIGENA, John Scotus, a scholastic philosopher, born near the beginning of the 9th century, in one of the British isles, probably Ireland. It is probable that he died about 880, but whether in France or England is uncertain. The most learned doctor and extraordinary thinker of his time, his life is best explained by supposing him to have been educated in Ireland, where a colony of philosophers had preserved almost intact, during the tumults of barbaric invasion, the traditions of the Alexandrian school of philosophy, elsewhere completely lost. Several writers agree in declaring that he travelled to Athens and acquired a knowledge of the Greek and oriental languages. Some old annalists identified him with John, abbot of Etheling, assassinated in 895, from which confusion Erigena enjoyed in some localities the honor of saintship. He went to the court of Charles the Bald of France before 847, was placed at the head of the school of the palace, and engaged in the religious discussions of his time concerning grace and the eucharist, and in philosophical speculations. The king imposed upon him the task of translating into Latin the Greek works of the pseudo Dionysius the Areopagite, and of composing a treatise against the doctrines of Godeschalcus or Fulgentius about predestination. He affirmed the eucharist to be a remembrance or commemoration of the sacrifice upon the cross; and in answering those who annihilated the freedom of the will, he elevated the moral nature of man to the exclusion of the efficacy of grace. His views were condemned by the councils of Valencia in 855 and Langres in 859, and Pope

Nicholas I. demanded his disgrace of Charles the Bald. From this point information concerning his career is entirely wanting. Many of his works are lost, including the treatises *De Corpore et Sanguine Domini*, *De Visione Dei*, excepting an unimportant fragment, and *De Egressu et Regressu Animæ ad Deum*. His most important work remains, *De Divisione Nature*, which was first published at Oxford in 1681, and was republished in 1838, with notes by Schlüter, at Münster in Germany. An abstract of it is given in Sharon Turner's "History of the Anglo-Saxons." It contains all his philosophy, in the form of a dialogue between master and pupil upon the universe, nature, and what is termed that grand universality of being which embraces at once God and man. The human intelligence, according to him, is inhabited by emanations from the divine intelligence; our ideas are pure theophanies, or manifestations of the Creator in his creature. He divides nature into four categories: 1, God, who possesses and diffuses life; 2, the first causes or eternal ideas by which he accomplishes his work; 3, the sensible world of the creation, of which man is the summit; 4, God as he shall be at last when the perfected world, its destiny being accomplished, shall return to him. Several of his theological works were refuted by contemporaries; but the pantheistic consequences of his philosophical system were not formally condemned until the council of Paris in the 13th century. After the barbarous ages which followed the northern invasions, Erigena rose suddenly to the heights of metaphysics, undertook to reduce the Christian faith to a scientific system, and founded the philosophy of the middle ages. He was intimate with the ideas of Plotinus, Proclus, and the Greek fathers, and has been ranked as at once the last of the Neo-Platonists and the first of the scholastics.

ERIVAN. I. A Transcaucasian government of Russia, bounded by Georgia, Persia, and Turkish Armenia; area, 10,577 sq. m.; pop. in 1867, 435,658, of whom about 120,000 are nomadic and gypsy tribes, who are all Mohammedans, while the rest are Armenians. The principal river is the Aras or Araxes. The principal mountain is Mt. Ararat in the south. The country is rich in salt, gold, silver, and other minerals. **II.** A fortified city, capital of the government, on the Zenghi, an affluent of the Aras, 35 m. N. by E. of Mt. Ararat, and 116 m. S. by W. of Tiflis; pop. in 1867, 14,342. It is the seat of the Armenian catholicoi, the head of the entire Armenian church, who resides in the monastery of Etchmiadzin in the vicinity. It has a beautiful mosque, a large bazaar, a cannon foundry, and manufactories of morocco leather and of cotton fabrics. It is strongly fortified, is a station for caravans from Tiflis and Erzerum, and has considerable trade with Turkey, Persia, and Russia. It is thought to have been founded by an Armenian king in the 1st century of our era, and formerly occupied a site nearly a mile dis-

tant from its present one, to which it was transferred in 1635. In the vicinity, on a lofty rock, is an immense oval citadel, and the remnants of ruined cities are found in the surrounding plain. In the 16th century it became the residence of the Persian kings of the Sufi dynasty. Several times besieged and captured

of the Theiss, 66 m. N. E. of Pesth; pop. in 1870, 19,150, chiefly Roman Catholics and Magyars. It has weekly fairs, linen and cloth manufactories, and an important trade in wine, Erlau wine being the best red wine of Hungary. There are two warm springs here, much resorted to for diseases of the skin. The town

Erivan.

by the Turks, it returned under Persian domination about the middle of the 18th century. The Russians were repulsed from it in 1808, but took it in 1827, and their general Paskovitch received the surname of Erivanski. It was confirmed to the Russians by treaty in 1828.

ERLANGEN, a town of Bavaria, in the circle of Middle Franconia, on the river Regnitz, the railway from Bamberg to Nuremberg, and the Ludwig's canal, 11 m. N. N. W. of Nuremberg; pop. in 1871, 12,511. It has a university, opened in 1743, which is the only Protestant institution of the kind in Bavaria. It was attended in 1873-'4 by 445 students, and has faculties of theology, medicine, &c., a museum of natural history, a botanic garden, and a library of about 120,000 volumes. There are an insane asylum, a Protestant gymnasium, and other schools. Erlangen is renowned among German towns for its pleasant and cheerful appearance. It is divided into an old and a new town. The latter is well built, and owes its origin chiefly to French Huguenots, to whom it was assigned as a residence by Margrave Christian Ernest in 1686, after the revocation of the edict of Nantes. In remembrance of this prince, the new town is frequently called Christian Erlangen. The town has manufactories of hosiery and gloves, and many breweries. A monument, designed by Schwanthaler, in honor of Margrave Frederick of Baireuth, adorns the public square.

ERLAU (Hung. *Eger*), a town of Hungary, capital of the county of Heves, in a deep and charming valley, on the river Erlau, an affluent

has four suburbs and many stately public buildings. The cathedral, the archiepiscopal palace, several churches, and the hospital founded by Komáromy, are the most notable edifices; the lyceum (formerly the university), a gymnasium, the episcopal seminary, a normal school, and a school of design are the principal learned institutions. Erlau, important as a bishopric from the time of St. Stephen, became the seat of an archbishop in 1804. In former times, though it possessed strong fortifications, it suffered much from Tartar and

Turkish invasions, especially in 1552, when it repulsed under Stephen Dobó the repeated assaults of an immense Turkish army, and in 1596, when it was given up to the Turks by the foreign part of the Austrian garrison. Among the remnants of the old fortress the tomb of Dobó is still shown to visitors. Erlau was conspicuous during the revolution of 1848-'9 for the patriotic spirit of its inhabitants, and as the place whence Dembinski and Görgey started for their chief campaigns against the Austrians under Windischgrätz.

ERMAN. I. Paul, a German physicist, born in Berlin, Feb. 29, 1764, died Oct. 11, 1851. He first taught at the French gymnasium and the military school, and was professor of physics in the university of Berlin from its establishment until his death. His contributions to science embrace a wide range of subjects, and more especially magnetism and electricity. Having been for some time secretary of the academy for the physical sciences, he became on its reorganization joint secretary with the astronomer Encke of both the physical and the mathematical class. The galvanic prize instituted by Napoleon I. was awarded to him by the French academy of sciences in 1806. **II. Georg Adolf**, a physicist, son of the preceding, born in Berlin, May 12, 1806, died July 12, 1877. Between 1828 and 1830 he performed at his own expense a journey round the world, chiefly with the object of making a series of magnetic observations. Han-teen, sent by the Swedish government on a similar expedition to western Siberia, was his fellow trav-

eller as far as Irkutsk. Here they parted company, Erman proceeding to Kamtschatka, whence he sailed to the Russian colonies in America, and returned to St. Petersburg and Berlin by way of California, Tahiti, Cape Horn, and Rio de Janeiro. A description of his journey is embodied in his *Reise um die Erde* (5 vols. 8vo, Berlin, 1833-'42). An English translation of the portion of his travels relating to Siberia, by W. D. Cooley, appeared in London in 1848 (2 vols. 8vo.). He has also published separate works on the course of the river Obi and on the animals and plants collected by him on his journey, and has contributed largely to Poggendorff's *Annalen* and other scientific periodicals. Since 1841, assisted by many Russian savants, he has edited the *Archiv für wissenschaftliche Kunde von Russland*, which is one of the best authorities on the subjects of which it treats. For several years he has held the professorship of physical science at the university of Berlin.

ERMELAND (Pol. *Warmia*), a region of East Prussia, between the rivers Passarge and Frisching; area, about 1,600 sq. m.; pop. about 200,000. It has formed a bishopric successively under the Teutonic knights, under the crown of Poland, and, since the first partition of that country in 1772, under Prussia.

ERMINE, a name given to several weasels, of the genus *putorius* (Cuv.), inhabiting the northern parts of both hemispheres, and which in winter exchange their brown color for a white livery more or less pure. The European ermine (*P. erminea*, Linn.) is about 10 in. long, with the tail half the length of the body; in summer it is reddish brown above, whitish below, with the tip of the tail black; in this livery it is called the stoat in Great Britain. In winter the upper parts become white, with a yellow tint beneath, the tip of the tail remaining black at all seasons; in this color the fur was formerly highly prized, especially for ornamenting garments pertaining to royalty and offices of dignity; for the purity of its whiteness it was taken as the emblem of incorruptibility and integrity. This animal is widely distributed in northern Europe and Asia, extending its range to the highest latitudes visited by man. Its habits are sanguinary, like those of all its genus, though from its smaller size it does less mischief in the farm yard than the polecat; it attacks and kills rats, mice, moles, and young poultry, sucking their blood; it often domesticates itself in houses, where its destruction of rats and mice in part compensates for its damage to the farmer in the hen house. There are at least five North American weasels entitled to the name of ermine; but it is very improbable that the *P. erminea* is found on this continent. The animal called ermine by Audubon and Bachman, and considered by them the same as the European, was first described as a distinct species by De Kay as *P. noveboracensis*. The color in summer is chestnut brown above, whitish below and on the inner surface of the limbs; edge of

upper lip white, and end of tail black; in winter, in northern latitudes, the hairs are snowy white from the roots, except on the end of the tail, which is black for about $1\frac{1}{4}$ in.; south of Pennsylvania the color remains brown throughout the year. The head is depressed and acute;

Putorius noveboracensis in Summer Dress.

the ears are large and extend far round the meatus; the body is elongated, and the tail cylindrical, thickly clothed with fur about $1\frac{1}{4}$ in. long at the end; the limbs are short and stout; there are five toes on each foot, the inner the shortest, all covered with fur, which hides the naked pads on the soles; on each side of the under surface of the tail are glands which secrete an offensive musky fluid. The fur is short, but very soft. The length to root of tail is $10\frac{1}{2}$ to 11 in.; length of tail to end of hair $6\frac{1}{2}$ to 7 in., the bones extending about $5\frac{1}{2}$ in. It is a graceful, quick, and fearless animal, living under logs and heaps of stones, and in holes in rocks. It destroys rabbits, grouse, and domestic fowls much larger than itself; satiated with the blood of a single victim, it kills all within its reach from

Putorius noveboracensis in Winter Dress.

an instinctive propensity to kill; it has been known to destroy 40 fowls in a single night; from its vermiform body it is able to pursue hares into their burrows and the field mice into their galleries. Though occasionally destructive to poultry and eggs, it is much more a

benefactor to the agriculturist by killing the mice which devour his grain, potatoes, and grasses; it will soon rid a granary of the largest rats, and a field of the wheat-loving ground squirrels. It is not shy, and has been so far domesticated as to be employed like the ferret of Europe in hunting hares; it is easily taken in any kind of trap. It is not common anywhere; it prefers stony regions, and is solitary and nocturnal in its habits, though occasionally seen at all hours of the day. It is a poor swimmer and avoids water, and rarely ascends trees except when pursued. The young, from four to seven in number, are born between the last of March and the last of May, according to latitude. The coat is shed twice a year, in October and March, the autumn fur becoming white, and the spring brown. According to Prof. Baird, this species cannot certainly be traced N. of Massachusetts nor W. of Wisconsin; it has been taken at Fort Smith, Ark., and probably is found in most of the southern and southwestern states at a distance from the seacoast. The most striking differences between this and the European ermine are, that in the latter the caudal vertebræ are only a quarter the length of the head and body, the terminal hairs being nearly two thirds of their length, or from $1\frac{1}{4}$ to $2\frac{1}{2}$ in.; while in the former these vertebræ are nearly half the length of the body, the hairs being only about a quarter of their length, or not more than $1\frac{1}{2}$ in.; in our species the ears and naked portion of the nose are larger; the coloration also differs in the much greater extension of the light colors on the lower parts and inside of the limbs in the European animal, and in the greater comparative extent of the black tip to the tail; there are 4 sacral and 21 caudal vertebræ in our ermine, and only 3 of the former and 19 of the latter in the European. The little ermine (*P. Richardsonii*, Bonap., or *P. agilis*, Aud. and Bach.), which replaces the preceding species north of Massachusetts, is from 8 to 9 in. long, exclusive of the tail, which is slightly more than 5 in.; the color in summer is dark chestnut brown above and whitish below, with the whole upper jaw brown, and the end of tail black one third to nearly one half of its length; in winter white with a black-tipped tail. It is smaller and darker, with more slender and delicate feet, than the preceding species; its geographical distribution is from 65° N. to Massachusetts on the E. and Vancouver island on the W. coast. The long-tailed ermine (*P. longicauda*, Rich.) approaches the ferrets in size, being about 11 in. long exclusive of the tail, which is 6 to 7 in.; the color in summer is light olivaceous brown above, and brownish yellow below, with the chin and edge of upper lip white; in winter white, with a black-tipped tail; the muzzle is broad, the hair short, coarse, and stiff, and the ears low and short; the feet are large, with well developed claws. It is found about the upper Missouri and Platte rivers. The least ermine (*P. Cicognanii*, Bonap., or *P. fuscus*,

Aud. and Bach.) has an average length of 8 in., with a tail of 3 or 4 in.; the colors are as in the other species in summer and winter; the edge of the upper lip is white; it is found from Labrador to Massachusetts, and as far west as Puget's sound. Kane's ermine (*P. Kanei*, Baird) is about $8\frac{1}{2}$ in. long, with a tail of 4 in.; it seems a miniature of the European species, and is found in Siberia and the vicinity of Behring strait.

ERNE, Lough, a lake of Ireland, county Fermanagh, consisting of two sheets of water, called the upper and lower lakes, connected by a narrow winding channel. It is fed by the river Erne, which, rising in Lough Gowna, flows N. through county Cavan, and expands near Crum into the upper lake. This is about 12 m. long, from 2 to $2\frac{1}{2}$ m. wide in its broadest part, and has a general depth of 20 ft., although in some places it is 75 ft. deep. There are 90 small islands in it, and the shores are generally low and marshy. The lower or northern northerly lake is 20 in. long, from 2 m. to 5 m. wide, and has a depth in some places of 225 ft. It contains 28,000 acres, and has 109 islets; Boa island, the largest, near the N. end, contains 1,300 acres. Both lakes abound with fish. The town of Enniskillen is partly situated on an island in the connecting channel, and there are a number of handsome residences and some well preserved ruins along its banks. The river leaves the N. end of the lower lake, and after a course of 8 m. empties into Donegal bay.

ERNEST AUGUSTUS, king of Hanover, fifth son of George III. of England, born June 5, 1771, died Nov. 18, 1851. He was for many years a member of the British house of lords as duke of Cumberland, and was a field marshal in the British army. Against the desire of his mother, he married in 1815 Frederica Caroline of Mecklenburg-Strelitz, widow of Prince Louis of Prussia and of the prince of Solms-Braunfels. The grant which he asked from parliament on occasion of his marriage not being accorded to him, he took up his residence in Germany, but returned to England in 1829 to vote against the Catholic emancipation bill, although it was proposed by his former political friend, the duke of Wellington. He again applied to parliament for money, for the education of his son George Frederick; but as it was only granted under condition that the young prince should be instructed in England and in the spirit of English institutions, he was compelled to remove his family from Germany. Grave imputations upon his private character, and his unbending opposition to all popular reforms, combined to make his residence in England as disagreeable to himself as it was hateful to the people. On the death of William IV. (June 20, 1837) the crown of Great Britain devolved on Queen Victoria, and the succession to the throne of Hanover being limited to the male line, the two countries were separated, and the duke

of Cumberland, eldest surviving brother of William, ascended the throne of Hanover. Here he became notorious for his tyrannical disposition. His first act was to abrogate the constitution of 1833, which had been sanctioned by William IV. In 1848 he yielded for a time to the exigencies of the moment, and granted a more liberal constitution. Shortly before his death he concluded a treaty with Prussia, by which Hanover joined the German Zollverein (Sept. 7, 1851). He was succeeded by his son, George V. (born May 27, 1819), who, though blind, reigned till Hanover was annexed to Prussia in 1866, when he took up his abode at Hietzing, near Vienna.

ERNESTI. I. Johann August, a German philologist, born in Tennstädt, Thuringia, Aug. 4, 1707, died in Leipsic, Sept. 11, 1781. He was made professor of ancient literature in the university of Leipsic in 1742, of eloquence in 1756, and of theology in 1758. His critical editions of Greek and Roman classics, Xenophon, Homer, Callimachus, Polybius, Suetonius, Tacitus, and Cicero are justly celebrated, especially the edition of Cicero's writings, and the glossary appended thereto, *Clavis Ciceroniana* (6th ed., Halle, 1831). His excellent Latin style obtained for him the surname of the German Cicero. As a theological writer he belonged to the school of rationalists. His most eminent theological work is the *Institutio Interpretis Novi Testamenti* (3d ed., 1775), of which an English translation, by C. H. Terrot, appeared in Edinburgh (2 vols. 12mo, 1833-43). **II. August Wilhelm**, nephew of the preceding, born at Frohndorf, near Tennstädt, Nov. 26, 1733, died in Leipsic, July 29, 1801. In 1765 he was professor of philosophy in the university of Leipsic, succeeded his uncle as professor of eloquence in 1770, and edited the works of Livy (1769) and Ammianus Marcellinus (1773), besides many others.

ERNST, Heinrich Wilhelm, a German violinist and composer, born in Brunn in 1814, died in Nice, Oct. 8, 1865. He played in public at the age of 10, studied under Joseph Boehm of Vienna, and also under Mayseder and Seyfried. In 1829 he made his first professional tour, exciting much attention at Munich, Stuttgart, and other musical centres. In 1832 he went from Vienna to Paris, where he remained several years studying the violinists of the French school, especially De Bériot, whose favorite pupil he became. In 1840 he resumed his professional tours, in the course of which he visited Vienna, Berlin, and most of the other German cities, and later Poland, Russia, Sweden, Denmark, and England, where he remained several years. During the last eight years of his life he resided at Nice, an invalid suffering under a nervous malady that impaired his powers and rendered his life unhappy. Among the best known and most frequently played of his works are his *Elegie*, the concerto in F sharp major, his quartets for stringed instruments, and his violin studies. His fame,

however, rested principally upon his great merit as a virtuoso. He was called the most poetic of violinists, combining the grace and elegance of De Bériot with a deeper feeling and a larger and grander tone. In his best days he was almost without a rival in Europe.

EROS, in Greek mythology, the god of love. There are two distinct conceptions of Eros. In the earlier, which appears in Hesiod, and in Plato, Aristotle, and the Orphic hymn, he is one of the oldest of the gods, or even the first of the gods. Hesiod associates him with Chaos, Ge (Earth), and Tartarus. He is elsewhere described as a son of Cronos (Saturn) and Ge, or as a god who had no parentage and came into existence by himself. He was one of the fundamental causes in the formation of the world, inasmuch as he was the uniting power of love, which brought order and harmony among the conflicting elements of Chaos. The Romans gave this divinity no place in their religion, but when they speak of what they had heard from the Greeks translate Eros into Amor. The Eros of the later Greek poets is identical with the Latin Cupid, and is one of the youngest of the gods. He is generally called the son of Aphrodite (Venus), though sometimes of Polymnia, Penia, Artemis (Diana), or Iris; and his father is variously said to be Zeus (Jupiter), Porus, Hermes (Mercury), Ares (Mars), or Zephyrus. He was generally described as a handsome youth, but in the latest poets as a wanton boy full of tricks and cruel sports. In this stage he is the god of sensual love, bearing sway over the gods as well as over men, taming lions and tigers, and depriving Hercules of his arms and Zeus of his thunderbolts. His arms are arrows and torches, which no one can touch with impunity. He has wings. His eyes are sometimes covered, so that he acts blindly. He is the usual companion of his mother Venus. His statue and that of Mercury stood in the Greek gymnasia. The number of the loves is extended by later poets, who make them sons of Venus or of nymphs. Thespiæ in Bœotia was the most famous place for the worship of Eros; there it was very ancient, and the old representation of the god was a rude stone, to which exquisite sculptures were added in later times. A quinquennial festival, the Erotidia or Erotia, was celebrated there in honor of the god. The goose was sacred to him, also the hare, the cock, and the ram. He was a favorite subject with the ancient statuaries, and Praxiteles represented him as a full-grown youth of perfect beauty. Respecting the connection between Eros and Psyche, see **PSYCHE**.

EROSTRATUS, or *Hierostratus*, an Ephesian who lived in the middle of the 4th century B. C., and whom a deed of infamy has given a place in history. On the night in which Alexander the Great was born, in 356 B. C., he set fire to the great temple of Diana at Ephesus, which was utterly destroyed. When it was ascertained who had perpetrated the sacrilege, Eros-

tratus was arrested and put to the torture. Being asked why he had committed such an act, he replied, "To make my name immortal." The Ephesians thereupon passed a decree consigning his name to oblivion; but this ordinance proved vain, for Theopompus mentions the name in his history.

ERPENIUS, or **Van Erpen**, **Thomas**, a Dutch orientalist, born in Gorkum, Sept. 7, 1584, died in Leyden, Nov. 18, 1624. He was educated at the university of Leyden, travelled in England, France, Germany, and Italy, and perfected himself at Paris and Venice in Arabic, Turkish, Persian, and Ethiopic. In 1612 he returned to Holland, was appointed oriental professor at the university of Leyden, and established a press for the printing of Arabic works, with Latin translations by himself. He was subsequently appointed oriental interpreter to the Dutch government. He wrote many important works, including an Arabic grammar which remained the standard text book for more than a century.

ERSCH, **Johann Samuel**, a German cyclopædist, born at Glogau, in Prussian Silesia, June 23, 1766, died in Halle, Jan. 16, 1828. He was educated in the universities of Halle and Jena, and was afterward connected in Halle with Meusel's periodical, *Das gelehrte Deutschland*, and in Jena with a political journal. He published a voluminous collection of the documents found in German political, geographical, and scientific periodicals (3 vols., 1790-'92), which created a great sensation among German bibliographers. His efforts were so much encouraged by prominent savants, that he was induced to undertake a digest of literature in connection with a general literary gazette. Eight volumes (Jena and Weimar, 1793-1809) were required to epitomize the literary productions of 15 years (1785-1800). Not only books, but also newspaper and magazine articles, were recorded, and even the criticisms to which the respective literary productions had been subjected were referred to with the utmost precision. While this was in progress, he projected a universal cyclopædia of modern literature, which he carried out so far as to publish five volumes on French literature, *Das gelehrte Frankreich*, and an edition of the same in French under the title of *La France littéraire* (1797-1806). He was also engaged during the same period in various editorial labors. In 1803 he accepted the chair of geography and statistics at the university of Halle. He crowned the labors of his life by establishing in conjunction with Gruber the *Allgemeine Encyclopädie der Wissenschaften und Künste*, of which 17 volumes (the first appearing in Leipsic in 1818) were edited by Ersch and Gruber. This is the most learned and elaborate German cyclopædia, and is still unfinished. (See CYCLOPÆDIA.) A third edition of his *Handbuch der deutschen Literatur seit der Mitte des 18ten Jahrhunderts bis auf die neueste Zeit* (2 vols., Amsterdam and Leipsic, 1812-'14) was pre-

pared by Geissler, who added to it a cyclopædia of philology in 1845 and of philosophical literature (Leipsic, 1850).

ERSE. See CELTS, LANGUAGES AND LITERATURE OF THE.

ERSKINE, **Ebenezer**, a Scottish theologian, founder of the Secession church of Scotland, born June 22, 1680, died in Stirling, June 22, 1754. The son of a Presbyterian clergyman, he was educated at the university of Edinburgh, licensed to preach in 1702, became pastor the next year in Portmoak, and held that post 28 years. Here and at Stirling, where he lived from 1731 until his death, he was a great favorite with his parishioners, as well as with the church throughout Scotland. The dissensions in the church of Scotland began in 1720, when the book entitled "The Marrow of Modern Divinity" was thought to reveal latitudinarian tendencies dangerous to the prevalent doctrines. Refusing to take the abjuration oath, and opposing the reimposition of lay patronage, as contrary to the act of union and to the liberties of the Scottish church, and at the same time being one of the most influential defenders of what were termed the "Marrow" doctrines, Mr. Erskine was proclaimed in many polemical pamphlets an innovator in religion and a troubler in Israel, was censured by the synod, and on Nov. 16, 1733, was solemnly rebuked and admonished at the bar of the general assembly. Against this decision he with three other clergymen entered a protest; and as they continued the conduct for which they had been censured, they were suspended from their functions. This sentence was removed July 2, 1734; but the deposed brethren had meantime formed themselves into a separate consistory and received numerous accessions. In 1740 Erskine and his brethren were again deposed and ejected from their pulpits; but he assembled his people on Sundays in the fields, till a new meeting house was provided, in which he continued to preach to large congregations till his death. There have been many editions of his "Select Works" (3 vols., 8vo) and of selections from them; also of his "Life and Diary," by D. Fraser.

ERSKINE, **Thomas**, baron, a British jurist and statesman, the third son of Henry David, fifth earl of Buchan, born in Edinburgh, Jan. 21, 1750, died at Almondell, near Edinburgh, Nov. 17, 1823. After studying in the high school of Edinburgh and in the university of St. Andrews, he entered the navy as a midshipman in 1764, and resigned in 1768 for a commission in the army. In 1770, soon after his marriage, he went with his regiment to Minorca, where he remained two years. After three years more of military service, during most of which time he was stationed in English country towns, he entered Lincoln's Inn, and was called to the bar in July, 1778. In November of the same year he defended Capt. Baille, lieutenant governor of Greenwich hospital, in a prosecution brought by Lord Sand-

wich, then at the head of the admiralty, for an alleged libel on other officers of that institution in respect of its management, and at once attained distinction as an advocate. The immediate effect of this effort was his reception of 30 retainers before he left the court. In 1779 he appeared at the bar of the house of commons as counsel for a bookseller against the monopoly of the two universities in printing almanacs, and the bill introduced by the prime minister, Lord North, to renew the monopoly, was defeated. In 1781 he secured the acquittal of Lord George Gordon, impeached for treason as the head of the "no popery" rioters. His practice and reputation increased so rapidly that he received in 1783, at the suggestion of Lord Mansfield, then presiding in the court of king's bench, the patent of precedence at the bar, and in the same year was returned to parliament as member for Portsmouth. He was a supporter of Fox, and advocated that minister's famous East India bill; but his parliamentary speeches were inferior to his pleas at the bar. His best efforts were those in defence of the freedom of the press and the privileges of juries, and against the doctrine of constructive treason. In his defence of the dean of St. Asaph, charged with libel, he indignantly argued against the judge who refused to receive the verdict of "Guilty of publishing only." One of his most important speeches was delivered in 1789 on the trial of Stockdale, who had published a pamphlet containing severe reflections upon the conduct of the managers of the impeachment of Warren Hastings, and was arraigned for a libel against the house of commons. Erskine's defence of Stockdale established his reputation as the most consummate advocate of the age, and the doctrine expounded in his plea and sanctioned by the verdict became the foundation of the liberty of the press in England. In 1792 he acted as counsel to Thomas Paine, prosecuted as author of the "Rights of Man," and was therefore deprived of the office of attorney general to the prince of Wales, which he had held since 1783. In 1794 he defended Hardy, Horne Tooke, Thelwall, and others, who were arrested and committed to the tower on charge of political conspiracy and high treason. The trial of Hardy began Oct. 29, and though the indictment stated nine overt acts of high treason, the trial turned almost solely on the question of treasonable intention. The proceedings continued to the eighth day, but the ability and eloquence of Erskine gained a verdict of acquittal, and forced the highest admiration even from his opponents. Tooke was arraigned Nov. 10, and pronounced not guilty on the 20th; his acquittal was followed by that of Thelwall; and the government abandoned the other indictments. Erskine looked with favor upon the attempt at social renovation in France, and opposed the interference of England on behalf of the Bourbons. His pamphlet entitled "A View of the Causes and Conse-

quences of the Present War with France" rapidly passed through 48 editions. Upon the death of Pitt in 1806, and the formation of Lord Grenville's coalition ministry, Erskine was appointed lord high chancellor, and created a peer under the title of Baron Erskine of Restormel castle, in Cornwall; but this ministry was dissolved within a year. He passed the remainder of his life in retirement, subject to pecuniary embarrassments from the loss of his large professional income and from unprofitable investments; while his domestic relations were disturbed by an ill-assorted marriage made after the death of his first wife in 1805. He took part for the last time in the house of lords in 1820, on occasion of the trial of Queen Caroline. Lord Erskine was one of the greatest of English advocates, and his eloquence may be compared to that of Pitt, Fox, Burke, and Sheridan. He presented to parliament the bill for the abolition of the slave trade, pleaded the cause of the Irish Catholics, supported propositions for the reform of the penal laws, and spoke and wrote in behalf of the struggling Greeks. His noblest efforts were in the cause of constitutional freedom, and during the momentous struggles of the period in which he lived no public man had greater personal influence. He left but few productions in writing. His parody of Gray's "Bard" was published in the "Monthly Magazine;" he wrote a preface to Fox's speeches, a political romance entitled "Armata, a Fragment" (published anonymously in 1817), and a few political treatises; but the chief foundation of his fame is his numerous speeches, which retain in print the brilliancy of thought, copiousness of imagery, elegance of diction, and much of the fervor which rendered them so successful when delivered. Collections have been published of his speeches at the bar in favor of the liberty of the press and against constructive treason (by James Ridgeway, 4 vols. 8vo, London, 1810-11); of his speeches at the bar on miscellaneous subjects (1812); of his speeches at the bar and in parliament, with a memoir by Lord Brougham (4 vols. 8vo, 1847); and of his select speeches, with a memoir by Edward Walford (2 vols. 8vo, 1870).

ERYMANTHUS, in ancient geography, a river and mountain of Arcadia, in Greece. The river, according to some the modern Dimitzana, rises on the frontiers of Arcadia and Elis, and flows into the Alpheus. The mountain, east of the river, formed the western point of the northern barrier of Arcadia, and was covered with forests. In this mountain Hercules killed the famous wild boar.

ERYSIPELAS (Gr. *ἐρσην*, to draw, and *πῆλας*, neighboring, from its tendency to draw in the neighboring parts; called also *St. ANTHONY'S FIRE*, or in Scotland *Rose*), an inflammation of the skin characterized by redness, swelling, and burning pain, commonly spreading from a central point, and sometimes affecting the

subcutaneous cellular tissue. Idiopathic erysipelas almost invariably attacks the face; frequently it is preceded by loss of appetite, languor, headache, chilliness, and frequency of pulse; a deep red spot now makes its appearance, commonly on one side of the nose, swollen, firm, and shining, and is the seat of a burning, tingling pain. The disease gradually extends, often until the whole of the face and hairy scalp has been affected, but it is exceedingly rare for it to pass upon the trunk. Often, while it is still advancing in one direction, the part originally affected is restored to its normal condition. Commonly large irregular vesicles (*phlyctenæ*) filled with serum, precisely similar to those produced by a scald, make their appearance on the inflamed skin. The pulse is frequent, there is total loss of appetite, headache, prostration, restlessness, and sleeplessness, and commonly, particularly at night, more or less delirium. The complaint runs its course in about a week, and the general symptoms ordinarily abate somewhat before any decline is noticed in the local inflammation. In itself erysipelas of the face is ordinarily unattended with danger; but where it occurs in the course of other and exhausting diseases, it adds much to the gravity of the prognosis. In fatal cases the delirium is apt gradually to lapse into coma. Erysipelas is subject to epidemic influences; in certain seasons it is exceedingly prevalent, while in others it is rarely seen. The attack is favored by overcrowding and deficient ventilation. Hospitals, particularly in spring, are infested with it. Certain unhealthy states of the system predispose strongly to the disease, and an unwholesome diet and the abuse of alcoholic stimulants are commonly cited among its causes. We have seen that simple erysipelas is rarely fatal; consequently recoveries are common under a great variety of treatment. Usually it requires nothing more than to move the bowels by a mild laxative, and afterward to support the system by the administration of nutriment, and if necessary the use of quinine and wine whey. Where there is great prostration, stimulants may be administered freely. Systematic writers make a separate variety of the erysipelas of newborn children; it presents no peculiarity, however, except its greater gravity, in common with other diseases, in such delicate organisms. When erysipelas of the abdomen occurs in new-born children, it commonly has its point of origin in the recently divided umbilical cord. In some cases erysipelas, arising generally from some injury or excoriation, shows a tendency to advance in one direction while it passes away in another (*erysipelas ambulans*); in this manner it may pass over almost every part of the surface.—In phlegmonous erysipelas the precursory symptoms are more constant and severe, the pain more violent, the prostration greater; the redness is most strongly marked along the trunks of the lymphatic vessels, and the lymphatic glands are swollen;

the swelling of the skin is more considerable, it soon assumes a pasty consistence, and pits strongly on pressure. As the disease advances, the pain subsides, the redness is diminished, and fluctuation becomes evident; if left to itself, the skin, gradually thinned and distended, sloughs over a larger or smaller space, and pus mingled with shreds of dead cellular tissue is discharged. The disease indeed seems usually to be in the cellular tissue rather than in the skin, and sometimes the cellular tissue throughout a limb appears to be affected. It is a disease of great severity, and when extensive often proves fatal under the best treatment. In its treatment, the same general principles apply as in simple erysipelas. The patient's strength should be supported by a nutritious diet, and tonics and stimulants must often be freely administered. Early in the disease the skin should be freely divided down into the cellular tissue, to relieve the constriction of the parts and afford an opening to the discharges.

ERYTHEMA (Gr. *ἐρυθραῖν*, to redden), an affection of the skin characterized by a slight redness without determinate form. It is generally due to the action of some special cause, as the heat of the sun, &c. Where it is produced by the friction of two contiguous surfaces, as frequently occurs in infants and in fleshy persons, it is often called *intertrigo*. *Erythema nodosum*, the severest form of the disease, is characterized by the eruption of numerous red spots from one third of an inch to an inch in their longest (vertical) diameter. These spots are slightly elevated; after a few days their color deepens, and passing through various shades of blue and yellow, the skin resumes its normal color. The affection is apt to be attended with fever, depression of strength, and derangement of the digestive organs. Simple erythema needs no treatment beyond the employment of soothing applications; in intertrigo, the use of an absorbent powder, as lycopodium, starch, &c., may be advisable. *Erythema nodosum* is best treated by diet, rest, and a mild laxative; in some cases tonics and iron are useful.

ERYTHRÆAN SEA (Gr. *ἐρυθρὸς, ἐρυθραῖος*, red, ruddy), in ancient geography, originally the name of the whole expanse of sea between Africa on the S. W., Arabia on the N. W., Gedrosia on the N., and India on the N. E., including the two great gulfs, the Arabian and the Persian. In this wider sense the term seems to have been used by Herodotus, who designates by it both the Indian ocean, of the shape of which he was ignorant, and the Persian gulf, distinguishing the Red sea, the *yam suf* or weedy sea of the Hebrews, which he calls the Arabian gulf. The term *ἡ νοτὴ θάλασσα* (southern sea) appears in some passages of the same historian as identical with the Erythræan, in others as designating the more distant and less known region of the latter. Later and better informed geographers, distinguishing the separate parts of the sea,

applied to its main body the name of Indian ocean, and to its great gulfs the names of Persian and Arabian, while the term Erythraean sea (Lat. *Mare Rubrum*) was variously used by different writers until it became confined to the Arabian gulf. The sea is supposed by some to have derived its name from the Phenicians (Gr. *φοινίξ*, red), who according to Herodotus originally dwelt on its shores; and by others from the red or purple hues imparted by coral reefs to the waters of the strait which connects the Red sea proper with the Indian ocean.

ERYX, an ancient town of Sicily, occupying the side of a mountain of the same name (now Monte San Giuliano), on the N. W. coast of the island, near the promontory of Drepanum. Above it was a temple of Venus, on the summit of the mountain. It early became a dependency of Carthage, was for a short time under the sway of Syracuse, was captured by Pyrrhus in 278 B. C., reverted to the Carthaginians, and in the first Punic war was partially destroyed by Hamilcar, who converted it into a fortified camp, removing the inhabitants to Drepanum. A few years later it was taken by the Romans, but the city was surprised by Hamilcar Barca, and made his headquarters till the conclusion of the war, while the Romans continued to hold the temple as an impregnable fortress. The site of the ancient city is now occupied only by a convent, and that of the temple by a Saracenic castle, now a prison, surrounded by the town of San Giuliano.

ERZERUM. **I.** A province or vilayet of Asiatic Turkey, comprising the greater part of Turkish Armenia, and bounded N. by Trebizond, E. by the Russian dominions and Persia, S. by Kurdistan, and W. by Sivas; pop. estimated at from 400,000 to 600,000. It consists mainly of lofty table land, the elevation of which is estimated at 6,000 ft., traversed E. and W. by several ranges of mountains, between which lie rich and extensive valleys. Cultivation is here well attended to, and the soil produces a profusion of excellent fruits, rye, barley, and flax, and furnishes pasture for large herds. The climate in winter and spring is severe, and in summer the heat is excessive. The rivers Euphrates, Aras, Kur, and Tehoruk have their sources here. The mountains are inhabited mainly by Kurds, who acknowledge but a nominal allegiance to the

sultan. **II.** The capital of the province, and the principal city of Turkish Armenia, situated on the Kara-su or W. branch of the Euphrates, in a beautiful plain about 6,000 ft. above the level of the sea, 30 m. long and 20 m. broad, 110 m. S. E. of Trebizond, its nearest seaport. The population in 1829 was estimated at 130,000; but the large emigration of Armenians that year reduced it to about 45,000. A triple wall of stone which nearly surrounds the old part of the town, and a large massive citadel, encompassed by a double wall, and having four stout gates covered with plates of iron, are its principal defences. The citadel, however, is commanded by a hill in the neighborhood. The streets are narrow and filthy; the houses are mostly of wood, mud, or bricks dried in the sun; and the whole city is infested with savage-looking dogs. The principal buildings are the Greek and Armenian churches, and the custom

Erzerum.

house, besides which there are about 40 mosques and numerous caravansaries. Outside of the city are four suburbs. The caravans travelling from Teheran to Mecca usually halt here, and an active trade is carried on with all the adjacent countries. Shawls, silk, cotton, rice, indigo, tobacco, and madder are imported from the east, and broadcloth, chintz, cutlery, &c., from the west by the Black sea. The exports are furs, gall, and live stock.—Erzerum was built by a general of the emperor Theodosius II. about A. D. 415, and named Theodosiopolis. A little E. of it was the Armenian town of Arzen or Ardzen, the inhabitants of which, on the destruction of their place by the Seljuks in 1049, removed to Theodosiopolis. The name Erzerum is therefore supposed to be a corruption of *Ardzen Rum*, the Turks frequently applying the word Rum (or Rome) to any territory anciently recognized as a part of the Roman or Byzantine empire. Erzerum was twice destroyed by fire and pillage, and in

1829 was taken by the Russians under Paskevitch. Its position, which commands the road from Persia to Constantinople, renders it still an important military post, as it was in the time of its Byzantine masters, and also a point of great commercial interest. It is the seat of the Turkish governor general, of English and other foreign consuls, and of a United Armenian bishop; and it is the focus of the transit trade between Europe and Trebizond and central Asia and Persia. Several American missionaries reside here.

ERZGEBIRGE (Ger., Ore mountains), a range of mountains on the boundary between Bohemia and Saxony, and in its southern portion lying chiefly in Bohemia. It extends E. N. E. and W. S. W. about 100 m., and covers an average breadth of about 25 m. At its western extremity it connects with the range called the Fichtelgebirge, where the White Elster has its source. The river Elbe defines its E. extremity, flowing toward the north through the valley that separates the Erzgebirge from the Lusatian mountains. On the north the range slopes gently toward the plains of Germany, but on the south the descent is more precipitous, with deep and narrow valleys running down to the valley of the river Eger, which flows E. to the Elbe. The highest elevations are W. of the central part of the range. Here are the summits of the Keilberg, Fichtelberg, and Schwarzwald, all rising to a height of about 4,000 ft. above the sea. These are granitic peaks, but toward the Elbe, where the granitic rocks give place to sandstone, the elevation declines to a maximum of 1,800 ft. The range is traversed by six great roads, the most important of them connecting Prague with Dresden and Chemnitz. The valley of the Elbe admits the passage of the range by the railroad from Dresden to Vienna. The Erzgebirge has long been famous for its mineral productions, the most important of which are silver, tin, iron, cobalt, lead, and copper. Other mineral products are gold, found in small quantity, mercury, arsenic, bismuth, antimony, zinc, manganese, and sulphur. Coal is found in the lower country near Dresden and Zwickau, and porcelain clay at Aue, 12 m. S. E. of Zwickau, used in the royal manufactory at Meissen.

ESARHADDON, son and successor of Sennacherib, king of Assyria, reigned 680-667 B. C. He is the Sarchedon of Tobit, the Asaradinus of the Canon of Ptolemy, and the Asshur-akhiddin of the Assyrian inscriptions. (See ASSYRIA, vol. ii., p. 36.)

ESCAMBIA. I. A N. W. county of Florida, separated from Alabama on the W. by the Perdido river, bounded E. by the Escambia, and S. by the gulf of Mexico; area, 850 sq. m.; pop. in 1870, 7,817, of whom 2,880 were colored. It consists mostly of a level and not very productive country, covered with extensive pine forests. The chief productions in 1870 were 7,020 bushels of Indian corn, 13,970 of sweet potatoes, and 35,050 lbs. of rice. The value of

live stock was \$71,520. Capital, Pensacola. II. A S. W. county of Alabama, bordering on Florida, intersected by the Escambia and Conecuh rivers; area, about 600 sq. m.; pop. in 1870, 4,041, of whom 951 were colored. The Mobile and Great Northern and the Alabama and Florida railroads pass through it. The soil is sandy; pine abounds. The chief productions in 1870 were 30,390 bushels of Indian corn, 31,665 of sweet potatoes, and 605 bales of cotton. There were 8,785 cattle, 3,583 sheep, and 4,878 swine. Capital, Pollard.

ESCHEAT (law Fr. *eschet*, from *eschoir* or *échoir*, to fall out, or lapse), a failure in the regular descent of lands whereby the fee reverts to the original grantor or his heirs if they can be found, and if not, then to the sovereign, who, according to the feudal tenure, was the original source of title. Such a failure may occur for the want of heirs, or of such heirs as can inherit the particular estate. This could rarely happen as respects an absolute estate in fee, inasmuch as heirs may be sought to the remotest degree of collateral consanguinity on failure of lineal descendants; but it is not unfrequent where the estate is limited, as in the case of a marriage settlement by which the estate is to descend to the issue of the marriage, or of an estate tail by which a limitation is made to the heirs of a man's body or other specified heirs. In these and analogous instances, upon the failure of the heirs designated, although there may be others capable of inheriting generally, the title to the land reverts to the grantor if no other provision has been made in the deed creating the estate. The escheat in such a case is said to be *propter defectum sanguinis*. It may also occur by an obstruction of the descent *propter delictum tenentis*, that is, when there has been a conviction of felony; in which case, according to the old phraseology, there was a corruption of blood, so that the man thus convicted was deemed in law to have no heirs. A distinction was made between treason and other felonies. In the former case forfeiture to the crown intervened and prevented the escheat of the lands to the original proprietor; in the latter, the lands of the felon were intercepted by the crown for a year and a day, and then escheated to the lord of the fee. By statute 54 George III., c. 145, no attainder for felony except treason and murder is now permitted to defeat the right of the heir or other person who would by law be entitled to the estate, except during the life of the offender. By the common law bastards were not deemed to have any heirs except of their own bodies, for being without lawful parentage, they can have no collateral kindred; therefore upon the death of a person of illegitimate birth, leaving no issue and without will, his lands escheated. So in the case of a man dying intestate leaving only alien relatives; as they could not inherit, his lands would escheat. Formerly it was held that there could be no descent even to

natural-born subjects, between whom and the deceased there were lineal or collateral alien ancestors through whom they would be obliged to claim; but the statute 11 and 12 William III., c. 6, provides that an intermediate alien ancestor shall not impede the descent to one otherwise capable of inheriting.—The law of escheat in the United States varies from the English in several particulars. In New York, and generally in the other states, the ultimate property to lands is deemed to be in the people; and whenever in any private ownership there is a failure of descent by want of heirs, the property escheats to the people, or, as is more commonly said, to the state. The escheated lands are to be held, however, subject to all the trusts, encumbrances, &c., that they would have been had they descended; and authority is given to the courts of the state to direct a conveyance to the parties equitably entitled thereto. Conviction of any criminal offence except treason produces no forfeiture of lands or personal property; and where the punishment is imprisonment for life, the convict is deemed civilly dead, and his heirs take by immediate descent as they would upon his natural death. In the case of outlawry for treason there is a forfeiture of lands to the state during the life of the offender. The lands of a person dying intestate who is illegitimate do not necessarily escheat, but descend to his mother if living, or if she is dead, to the relatives on the part of the mother. As estates tail do not exist in the United States, many of the questions which arise in England upon the failure of particular heirs do not occur here. Properly speaking, an escheat to any private individual is unknown to our law. Not only feudal incidents, but the theory upon which they were founded, have been abrogated. In respect to aliens, a statutory provision similar to what has been enacted in England, as above mentioned, removes all disability of inheriting by reason of an intervening alien ancestor. Where property is purchased by an alien, or has been otherwise acquired, as by claim of inheritance, there being no other heirs, although by operation of law it escheats to the state, yet is his title good until divested by some proceeding on the part of the state to enforce the escheat; that is to say, it is valid against all other claimants, and even against the state itself until judgment has been rendered by some court declaring the escheat. In many of the states alienage of heirs is no longer a ground of escheat, aliens being allowed by statute to take by purchase or inheritance without restriction or impediment.

ESCHENBACH, Wolfram von, a German minnesinger, belonging to the circle of poets which near the end of the 12th and the beginning of the 13th century frequented the court of the landgrave Herman I. of Thuringia. He was of noble birth, fought under the banner of different lords in the civil wars of the time, and made his longest abode at the court of

Eisenach, in the mountain castle of Wartburg, where the landgrave Herman collected the most illustrious minnesingers. There he became associated with Heinrich von Veldeke, Walther von der Vogelweide, and other bards, and, according to tradition, engaged about 1207 in the poetical contest known as "the war of the Wartburg," and concluded by the magician Klingsor, the legends of which were collected in a famous poem about a century later. Eschenbach afterward sang at other courts, and died about 1225. Some of his poems are original, and others are imitations of troubadour songs and trouvère romances. Friedrich von Schlegel has called Eschenbach the greatest poet that Germany has produced. The first critical edition of his works was by Lachmann (Berlin, 1833; 2d ed., 1854). They have been turned into modern German by San Marte (Magdeburg, 1836-'41; 2d ed., Leipsic, 1858), and his *Parceval* and *Titurel* by Simrock (Stuttgart, 1842; 2d ed., 1857).

ESCHENMAYER, Karl Adolf August von, a German philosopher, born at Neuenburg, in Württemberg, July 4, 1768, died Nov. 17, 1852. From 1811 to 1836 he taught philosophy and medicine and afterward practical philosophy at the university of Tübingen. He produced a great variety of writings, chiefly on philosophy. His religious views are strongly tinged with mysticism, and several of his writings are directed against the theories of Hegel and against the "Life of Jesus" by Strauss. Among his principal works are *Religionsphilosophie* (3 vols. 8vo, Tübingen, 1818-'21), *Mysterien des innern Lebens, erläutert aus der Geschichte der Seherin von Prevorst* (Tübingen, 1830), and *Grundzüge einer christlichen Philosophie* (Basel, 1840).

ESCHWEGE, a town of Prussia, in the province of Hesse-Nassau, on the Werra, 27 m. S. E. of Cassel; pop. in 1871, 7,377. It consists of the old town on the left bank of the Werra, the new town on the right bank, and Brückenhäusen on a small island, connected with the other parts by stone bridges. It has an old castle, and manufactories of linen and woollen, leather, glue, soap, and oil.

ESCHWEILER, a town of Prussia, in the province of the Rhine, on the Inde, 8 m. N. E. of Aix-la-Chapelle; pop. in 1871, 15,550. It has manufactories of iron ware, machines, needles, wire, silk goods, ribbons, and leather. In the neighborhood are lead and coal mines.

ESCOBAR Y MENDOZA, Antonio, a Spanish casuist, born in Valladolid in 1589, died July 4, 1669. He was a Jesuit, distinguished for eloquence, and preached daily, and sometimes twice a day, during 50 years. He was also an indefatigable writer, and won a high reputation in his order for his works, which comprise over 40 volumes. His private life was marked by simplicity and purity; but the "probabilistic" principles on which is based the solution of many of his "cases of conscience" left him open to misconception and animadversion.

When Pascal, the great Jansenist writer, assailed the doctrines and morals of the Jesuits, Escobar's theology was selected by the satirist, as being the authorized teaching of the whole society. Although Pascal's *Lettres provinciales* were afterward condemned by the French episcopacy as heretical and defamatory, Escobar's name has continued to be held as typical of extreme laxity in morals; and the terms *escobarde*, *escobarde*, *escobartin*, then introduced into the French language, still signify the reconciling of one's religious convictions with one's interest and passions. Among his works are: *San Ignacio de Loyola*, an heroic poem (1613); *Historia de la Virgen Madre de Dios*, an epic poem (1618); *Summula Casuum Conscientiæ* (1626); and *Liber Theologiæ Moralis*, XXIV. *Societatis Jesu Doctoribus reseratus*, &c. (1646).

ESCURIAL (Sp. *el Escorial*), a palace and mausoleum of the kings of Spain, in Escorial de Abajo, a town of 2,000 inhabitants, in a bar-

ren region, 2,970 ft. above the sea, on the S. E. slope of the Sierra Guadarama, in New Castile, 25 m. N. W. of Madrid, with which it is connected by railway. The correct title of this celebrated palace is "El real sitio de San Lorenzo el real del Escorial," so called from having been built in fulfilment of a vow made by Philip II. that he would build the most magnificent monastery in the world if St. Lawrence would give him victory over the French in the battle of St. Quentin, fought on that saint's day (Aug. 10, 1557). St. Lawrence suffered martyrdom by being broiled on a gridiron, and by a quaint conceit of the king or his architects, the ground plan is in the form of a gridiron, with handle and bars complete. Voltaire and other French writers have claimed for a Frenchman named Louis Foix the honor of having been the architect of the Escorial; but it is beyond doubt that Juan Bautista de Toledo commenced it from his own plans, and on his death in 1567 it was continued by his pupil,

The Escorial.

Juan de Herrera. The foundation was commenced on St. George's day, April 23, 1563. Twenty-one years' labor and a sum equal to \$15,000,000 were expended in completing the work. The body of the gridiron is represented by 17 ranges of buildings, crossing each other at right angles, forming a parallelogram enclosing 24 courts, with a square tower 200 ft. high flanking each of the four corners of the edifice, thus representing a gridiron reversed, the towers being the upturned feet. A wing 460 ft. long represents the handle of the implement, and contains the royal apartments. The average height of the walls is 60 ft. The total length of the edifice is 740 ft. N. and S., and 580 ft. E. and W. It contains the royal palace, royal chapel, monastery with 200 cells, 2 col-

leges, 3 chapter houses, 3 libraries, 5 great halls, 6 dormitories, 3 hospital halls, 27 other halls, 9 refectories, 5 infirmaries, a countless number of apartments for attendants, 80 staircases, 1,110 windows looking outward and 1,578 inward, or, including outhouses, 4,000 in all, besides 14 gates and 86 fountains. The whole edifice is built of white stone spotted with gray, resembling granite, and quarried on the site. The general aspect of the Escorial is that of a freshly erected pile, rising from the midst of plantations, and more imposing from its magnitude than from grandeur of architecture. The Doric is the prevailing order. The E. and W. terraces overlook the slopes; the N. and W. sides front the mountain, and are connected with the village by a subterranean

gallery tunnelled in 1770 as a means of communication during storms. The most striking feature of the edifice is the church, built in general imitation of St. Peter's at Rome, in the form of a Greek cross with a cupola and two towers. It contains 40 chapels with their altars, and is 364 ft. long, 230 broad, divided into seven aisles, paved with black marble and roofed by the dome rising 330 ft. from the floor. The grand altar, 90 ft. high and 50 ft. wide, is of jasper and gilded bronze. Eighteen pillars, each 18 ft. high, of red and green jasper, support an estrade on which the altar is placed. Porphyry and marbles of the richest description incrust the walls, and on either side are statue portraits of the kings. Directly under the high altar, so that the host may be raised above the dead, is a mausoleum built by Philip IV., from a design after the Roman pantheon. This burial place is 36 ft. in diameter, with walls of jasper and black marble. Here the remains of all the sovereigns of Spain since Charles V. repose in niches one above another. Another burial place in one of the chapels is called the pantheon of the infants. Several fine paintings adorn the church, but it is much shorn of its embellishments since it was plundered by the French. Benvenuto Cellini's marble "Christ," presented to Philip by the grand duke of Tuscany, and brought from Barcelona on men's shoulders, is still shown here, and an immense collection of saintly relics amassed by the founder may also be seen. The interior of the church is a triumph of architectural effect, grand, massive, and solemn. On its steps are six colossal statues in granite, with marble heads and hands, and gilt crowns. These are called the kings of Judea. The edifice forms one side of a court, facing a finely sculptured portal, which opened twice for every Spanish monarch, once when he was carried through it after his birth, and once after his death, when three nobles and three priests bore him to the tomb. The royal apartments contain little worthy of notice, excepting two picture galleries, from which, however, most of the *chefs d'œuvre* have been removed to Madrid. The arched room of the great library is 194 ft. long, 32 wide, and 36 high. The ceilings were painted in fresco by Bartholomew Carducci. The library was said before the French invasion to have contained 30,000 printed and 4,300 MS. volumes, but we have no accurate estimate of its present contents. It is believed to contain between 4,000 and 5,000 MSS., of which 567 are Greek, 67 Hebrew, and 1,800 Arabic. The Arabic MSS. are not accessible to visitors. A portion of the library was destroyed by fire in 1671, and again in 1761; and the buildings were again seriously damaged from the same cause in October, 1872.

ESDRAS, Books of, two apocryphal books of the Old Testament, given as the third and fourth books of Ezra (the second being properly the book of Nehemiah) in several manuscripts of the Latin Vulgate, as well as in all

printed editions anterior to the decree of the council of Trent, which declared the two additional books uncanonical. In the English authorized version of the Apocrypha they are called 1st and 2d Esdras; in the Clementine and Sixtine versions of the Vulgate they appear at the end of the volume, being inserted, as expressly stated, in order to "preserve from being altogether lost books which had been sometimes cited by some of the holy fathers." Luther denounced the two books as worse than Æsop's fables; but the first was received into the Lutheran Bible, among the Apocrypha, while the second is counted among the pseudepigrapha. In all the manuscripts of the Septuagint, the first of these books, or the so-called third of Ezra, precedes the canonical books of the Jewish scribe, which in this version include that of Nehemiah. It is a recapitulation of the history related in the canonical book of the same name, interspersed with some interpolations taken from 2 Chronicles, Nehemiah, and other sources. It is written in an elegant style, resembling that of Symmachus, though it appears to be rather a version than an original work. The name and age of the author or translator are unknown. The 2d Esdras or 4th Ezra is of a different character from its apocryphal predecessor, and seems to owe its place among the uncanonical writings of the Old Testament only to the historical name which it bears. It contains a number of visions resembling those of the Apocalypse, related in a style acknowledged by prominent critics to rise occasionally to great sublimity of thought, energy of conception, and elegance of expression. This book also is supposed by some to be a translation from the Hebrew or Chaldee. But both the original and the Greek translation mentioned by Clement of Alexandria having been lost, the book was believed to exist only in the old Latin version, until more recent discoveries enriched Biblical literature with Arabic, Syriac, and Ethiopic translations. This book is ascribed to Ezra the scribe by Clement of Alexandria, and was regarded as prophetic by most of the fathers of the church, though it does not appear to have been known to Josephus. Jahn supposes the author to have been a Jew educated in Chaldea, and converted to Christianity, who flourished about the beginning of the 2d century. Dr. Laurence maintains that the author was a Jew who lived shortly before the Christian era; and he accordingly rejects as interpolations the first two chapters of the book, which furnish the chief argument for his acquaintance with the doctrines of Christianity. Dr. Lee conjectures the author to have been also the author of the book of Enoch. The Latin text is given in Hilgenfeld, *Messias Judæorum* (1869), and in the edition of the apocryphal books by Fritzsche (1871). The Ethiopic translation was published by Laurence in 1820.

ESK, the name of several rivers of Scotland. **1.** A river of Dumfriesshire, formed by

the junction of the Black and White Esk, runs S. E. to the English boundary, enters Cumberland, and falls into the Solway frith, after a course of about 80 m. **II.** A river of Edinburghshire, formed $1\frac{1}{2}$ m. N. of Dalkeith by the junction of two head streams called the N. and S. Esk, flows N., and empties into the frith of Forth at Musselburgh. **III.** North Esk, a river of Forfarshire, rises among the Grampian hills, flows S. E., chiefly along the boundary between Forfarshire and Kincardineshire, and enters the North sea near Montrose; length about 25 m. It has valuable salmon fisheries. **IV.** South Esk, a river of Forfarshire, rises in the Grampians, flows S. E. and E., and enters the North sea near the mouth of the North Esk. It forms a large basin at Montrose, but is navigable only a short distance from the sea. It has salmon fisheries.

ESKI-SAGRA, a town of European Turkey, in the province of Roumelia, on the S. slope of the Balkan, 70 m. N. W. of Adrianople; pop. about 20,000. It is in a fertile region, and near it are several mineral springs. It contains several mosques; but its general aspect is even more wretched than that of most Turkish towns. The principal manufactures are carpets and leather. Large quantities of roses are raised in the vicinity.

ESMERALDA, a S. W. county of Nevada, bordering on California; area, 7,850 sq. m.; pop. in 1870, 1,553, of whom 56 were Chinese. It contains Walker lake, and is watered by East and West Walker rivers. The land along the rivers and lake is fertile. In this county is the great salt basin, 16 m. long and 3 m. wide, which is covered with pure salt. The White mountains are in the S. W. part. Gold and copper are found. Nine quartz mills are in operation, mostly for the production of silver. The chief productions in 1870 were 185,400 bushels of wheat, 103,920 of barley, and 4,405 tons of hay. There were 2,191 horses, and 6,078 cattle. Capital, Aurora.

ESMERALDAS. **I.** A river of Ecuador, the largest of those emptying into the Pacific. Its head waters are said to descend from the mountains Cotopaxi, Sincholagoa, Tiopullo, and Moreta, but it does not take the name Esmeraldas until the junction of the Guailabamba and Blanco in lat. $0^{\circ} 30' N.$, from which point it holds a nearly N. course, almost wholly through dense forests, and falls into the ocean 10 m. below the town of Esmeraldas. Its mouth, on the W. side, is obstructed by sand banks, and it is not navigable for more than one third of its length, owing to cataracts and the inequality of its bed. The circumstance to which it owes its name really belongs to the Rio Quinindé, one of its tributaries, on the banks of which were once extensive mines of gold and emeralds. **II.** A province occupying the N. W. portion of Ecuador, and watered by the preceding river, bounded N. by Colombia, and W. by the Pacific ocean; area and population uncertain. On its coasts are the bay of

Ancon and the port of Pailon, besides that of its own name. The province is chiefly covered with forests, affording excellent timber for building, and various ornamental woods; which, with cacao, little inferior to that of Carácas, and tobacco of good quality, form the chief products. The inhabitants, almost exclusively mulattoes and zambos, live mainly on the banks of the rivers, and are occupied in the preparation of cacao and tobacco, and the manufacture of rum. There are few facilities for transport besides the rivers and a wretched road over the Cordillera to Quito. Education is at the lowest ebb; and although there are rich deposits of gold, iron, and emeralds, and a soil of unsurpassed fertility, the province is in a very primitive condition. It has five villages: Esmeraldas, Atacames, Rioverde, La Tola, and Concepcion. The new town of Esmeraldas, the present capital, is on the river Esmeraldas, 10 m. from its mouth, and 110 m. N. W. of Quito, with an excellent harbor. The old town of the same name, the former capital, is 6 m. further up the river. The climate is very hot, and both towns have not more than 1,500 inhabitants.

ESNE, or **Esneh** (anc. *Lato* or *Latopolis*), a town of Upper Egypt, on the left bank of the Nile, lat. $25^{\circ} 20' N.$, 28 m. S. S. W. of Thebes; pop. in 1870 estimated at 12,000. Until within a few years it was a dirty, poverty-stricken place, with mud houses, and in 1834 it was selected as a place of banishment for the ghawazi or dancing women of Cairo, and other females

Remains at Esne.

obnoxious to the laws. It is the emporium of the Abyssinian trade, contains manufactories of cotton goods, shawls, and pottery, and is a celebrated camel market. It is the seat of a Coptic bishop, and has three Coptic churches. The ancient city was large and important,

and its remains are mostly buried under large mounds covering the adjacent country. In the centre of the modern town, surrounded by filthy hovels, stands the portico of a great temple, in a fine state of preservation. It is supported by 24 massive pillars, each $5\frac{1}{2}$ ft. in diameter and 40 ft. high. The portico is 112 ft. long, 53 ft. broad, and covered with sculptures and hieroglyphics. On its ceiling is a zodiac, like that of Denderah; over the dedication at the entrance are the names of Tiberius Claudius Cæsar, Germanicus, and Vespasian, and within occur those of Trajan, Hadrian, and Antoninus. The hieroglyphic inscriptions show that the oldest part of the temple was built by Ptolemy Epiphanes, about 200 B. C.; the portico was erected by the emperor Claudius, about A. D. 50; other portions are of still later date, the latest being erected by Vespasian, about 70. In 1843 Mehemet Ali had it cleared of the rubbish which filled the interior, and used it as a cotton warehouse.

ESPARTERO, *Joaquín Baldomero*, duke de la Vitoria, a Spanish soldier, born at Granatula, near Ciudad Real, Feb. 27, 1792, died at Logroño, Jan. 9, 1879. He was the son of a wheelwright, and was intended for the church, but in 1808 entered the army. In the war against the insurgents of South America, he fought in Venezuela and Peru, and rose to the rank of brigadier general. After the surrender of the Spanish troops at Ayacucho in 1824, he returned to Spain with a considerable fortune. He favored the succession of Isabella II. to the throne, and the appointment of Queen Christina as regent during her minority. Upon the breaking out of the civil war after the death of Ferdinand VII. (1833), he was made commander-in-chief of the province of Biscay, and afterward lieutenant general. In the contest with the Carlists he displayed energy and ability, and was appointed general-in-chief of the army of the north, viceroy of Navarre, and captain general of the Basque provinces. In December, 1836, with the assistance of the British fleet, he drove the Carlists from Luchana, raised the siege of Bilbao, and was created count of Luchana. As a member of the constituent cortes he supported the new constitution of 1837. In that year he compelled the army of Don Carlos, which had advanced to the walls of Madrid (September), to retreat across the Ebro; in 1838 defeated the Carlist generals Negri and Guergué; and having gained new victories early in 1839, was created a grandee of the first class, with the title of duke de la Vitoria and of Morella. In August, 1839, he concluded with the Carlist general Maroto the convention of Vergara, which amounted to a submission on the part of the Carlists. Don Carlos left the country, and Cabrera, the only Carlist general who remained, was soon after defeated by Espartero. Queen Christina endeavored to strengthen her power by placing Espartero at the head of the ministry; and when in 1840 she was compelled

to resign the regency and retired to France, Espartero was appointed regent. During his administration insurrections broke out in different parts of Spain, especially at Pamplona and Barcelona. Espartero asserted his authority with ability and energy, refused several demands of the Christinos, and gave further offence by some commercial arrangements with England. A revolutionary junta assembled at Barcelona in 1843, and declared that Isabella had attained her majority, and that the regency was at an end. Espartero was deserted by all parties, and Narvaez, his personal enemy, in July entered Madrid in triumph at the head of an army. Espartero retired to England, where he resided till 1847, when he was restored to his honors, and resumed his position as senator. When Christina was again forced to leave Spain in 1854, Espartero was placed by Queen Isabella at the head of the cabinet, O'Donnell, the principal leader of the Christinos, being made minister of war. This coalition ministry was short-lived, and Espartero resigned in July, 1856. After the expulsion of Queen Isabella in 1868, he supported the provisional government. In 1870 several members of the cortes offered him the crown, but he declined it on the ground of his great age and his want of heirs.

ESPARTO, a species of grass or rush belonging to the genus *stipa*, a native of the south of Europe and the north of Africa. It abounds in southern Spain, where it is much used in the manufacture of cordage, nets, sacks, mats, baskets, &c., for which it is well adapted by the great strength of its fibre. The sandals called *alpargates*, worn by the Spanish peasantry, are made from it. Esparto cables are used in the Spanish navy, being considered superior to hemp, because from their lightness they float on the water, and are not so liable to be cut by a rough bottom.

ESPINASSE, *Mlle. de P.* See **LESPINASSE**.

ESPINEL, *Vicente*, a Spanish poet, born in Ronda, Andalusia, about 1545, died in Madrid about 1634. His father's name was Francisco Goma, but, according to a Spanish custom, he adopted the name of his maternal grandmother. He was educated at Salamanca, and afterward led an adventurous life in various parts of Europe. In his latter years he held an ecclesiastical office in his native town, though he passed much of his time in the capital. He was in pecuniary trouble through the whole of his career, and died in poverty, although he was the recipient of a pension from the archbishop of Toledo. Espinel was prominent among the Spanish poets of the 16th and 17th centuries, and some of his *canciones*, *redondillas*, pastorals, and elegies are spirited, picturesque, and harmonious in versification. He was also proficient in music, and is said to have added a fifth string to the guitar, which soon led to the invention of the sixth. But his chief work is his *Relaciones de la vida del escudero Marcos de Obregon*, which first ap-

peared at Barcelona in 1618, and has since passed through several editions in Spain. An English translation was made by Algernon Langton (London, 1816), and Tieck wrote an imitation in German (Breslau, 1827). Voltaire accused Le Sage of plagiarism, and denounced the "Gil Blas" as taken entirely from Espinel's "Marcos de Obregon."

ESPIRITO SANTO, a S. E. province of Brazil, on the Atlantic, bounded N. by the province of Bahia, S. by that of Rio de Janeiro, and W. by Minas Geraes; area, 14,049 sq. m.; pop. about 65,000. A very large proportion of the inhabitants are savages, dwelling in the interior, mostly descendants of the ancient Tupis and Aimorés, the latter being called Botocudos. The capital is Victoria. A branch of the Serra do Mar, here called Serra dos Aimorés, forms the natural western boundary, and throws off in regular succession a number of spurs, some of which gradually lower down to the coast, where they form abrupt rocky bluffs. The valleys between these hills are often very little broader than the rivers by which they are drained. There are some streams of considerable magnitude, the principal of which are the Mucury, which separates the province from that of Bahia, and the Doce. But few of the rivers are favorable to navigation, owing to their rapidity, irregular depth, and many cataracts. There are numerous lakes, mostly in connection with the rivers which empty directly into the ocean. There are few ports worthy of the name, Benevente being the best, and able to receive ships of considerable tonnage at any time of the tide. Victoria has an excellent harbor, but, on account of the barrenness of the surrounding country, will probably never be of much importance; and the mouth of the Doce is so dangerous as to render it useless for a port. Impervious forests cover the regions adjacent to the rivers; the plains toward the coast are pretty equally divided into meadow land and marsh; and altogether but little of the country has been brought under cultivation, notwithstanding the fertility of the soil, particularly N. of Victoria and S. of the Itapemirim. The chief products are maize, beans, coffee, mandioca, cotton and sugar in small quantities, and cacao, which is principally planted in the low grounds. Various attempts have been made to colonize the Doce, where is a great agricultural region; the chief cause of failure has been the ferocity of the aboriginal tribes. The rivers afford a plentiful supply of fish, nowhere surpassed for numbers of species and delicacy of flavor; and hosts of turtles are found along the coast. Rosewood is extensively exported, with some beans and other produce, and some coffee and sugar. The climate is generally hot, humid, and unhealthy.

ESPY, James P., an American meteorologist, born in Washington co., Pa., May 9, 1785, died in Cincinnati, O., Jan. 24, 1860. He early manifested a fondness for meteorological sci-

ence, and after some years of investigation announced a theory of the origin and causes of storms, one of the features of which was the possibility of producing rain on a large scale by artificial means, which led to protracted discussions on the subject in the scientific journals. In 1841 his "Philosophy of Storms" was published simultaneously in Boston and London. He had previously communicated to the British association a paper on storms, and another on the "Four Daily Fluctuations of the Barometer." In 1843 he was assigned by the war department at Washington to a post in connection with the observatory, that he might prosecute meteorological investigations, and collated the reports from the different observers throughout the country. The information thus obtained was published in several quarto volumes by the department.

ESQUIMAUX, or **Eskimos**, the most northerly of the American native tribes, residing chiefly above lat. 60° N., and occupying Greenland, Labrador, the shores of the Arctic ocean, and the coast on the Pacific down to the peninsula of Alaska, and also a portion of the adjacent Asiatic coast. They are generally divided by writers into the Karalits or Greenlanders, the eastern or Labrador Esquimaux, the Iglik or central, the Kotzebue sound or western, and the Tchuktchis in Asia. They call themselves Inuit (men). The name Esquimaux, applied to them by the Algonquins, means raw fish eaters. The early Norwegian settlers in Greenland called them Skroellings. They finally expelled the Norwegians from their country about the 14th century. Cartier heard of them, and his successors before the end of the 16th century traded with them on the Labrador coast; but the Basques by violence provoked them to war. They were in constant hostilities with the Algonquins, who at last drove them from the gulf of St. Lawrence, where Champlain places them on his map. They worshipped Torngak, an old man, god of the sea, and Supernukoak, goddess of earth. They are hardy, ingenious, active, and industrious, showing considerable skill. Crantz describes the Greenlanders as small but well proportioned, broad-shouldered, generally less than 5 ft. high, with high cheek bones, flat faces, small lustreless black eyes, round cheeks, small but not flat noses, small round mouths, long, straight, coal-black hair, large heads and limbs, and small soft hands and feet. They root out the beard, and are inclined to corpulence. Their body is of a dark gray color, but the face brown or blue. This brown color seems not altogether natural, because their children are born as white as others, but it is due in part to their habits; for they are constantly handling grease, and seldom wash themselves. Lesson describes them as superstitious to excess. Polygamy is practised, and women are regarded as creatures of an inferior order, to be disposed of by the men according to their pleasure. Their dwellings are almost invariably near

the seashore, and are either permanent or temporary according to the situation and the materials at the disposal of the workman. In Greenland, where their permanent dwelling is of stone cemented by turf, it is usually not more than 6 or 8 ft. high, and is covered by a flat roof of wood and turf. It has neither door nor chimney, and the floor is divided into compartments by skins attached to the posts that support the roof. Each family has a separate apartment, and each apartment a window of seal skin dried, which is white and transparent. Benches are used as seats during the day and as couches during the night, the bedding being composed of reindeer skins. In Gilbert sound the houses are of wood, and at Regent's bay, and generally in Labrador, the roof is arched, and the habitation sunk 3 ft. in the ground; but the most remarkable houses are those built of the bones of whales and walruses, described by Frobisher and Parry. They also construct dwellings of snow and ice. Their dress consists of furs, in the preparation of which they exercise a degree of ingenuity superior to that of the most skilful furrier. The winter coat is usually made of seal skin, while the summer coat consists of that of the reindeer; but every variety of fur is occasionally used. The overcoat is supplied with a large hood, often bordered with white fur of the deer, which when drawn over the head presents a lively contrast with the dark face of the wearer. Those worn by the women have a much larger hood than those of the men, which not only furnishes a covering for the head but a cradle for the infant. The boots of the women are remarkable, and are sometimes made so large in the leg as to resemble a leather sack, which gives a ludicrous aspect to the whole figure. These capacious pouches are used as pockets, as temporary beds for infants, and, when in the vicinage of white men, as receptacles for stolen goods. As they are much upon the water, they devote considerable attention to the construction of their boats. These are of two kinds, the *caiak* or men's boat, and the *oomiak* or women's boat. The *caiak*, first described by Baffin, is adapted but for one person; it is about 16 ft. long, 2 ft. broad in the middle, and 1 ft. deep, and shaped like a weaver's shuttle. The bottom is rounded and has no keel. The frame is kept stretched above by 22 little beams, and two, strong battens run from stem to stern, which toward the middle are attached to a hoop of bone large enough to admit the body. The frame is entirely covered, with the exception of a circular hole in the centre, with fresh-dressed seal or walrus skin. When complete the boat weighs about 60 lbs., and is so constructed that it can be carried on the head without the aid of the hands. The *oomiak* is from 20 to 25 ft. long, 8 ft. broad, and capable of accommodating from 10 to 20 persons. It is composed of the same materials as the *caiak*, and is often fur-

nished with a lug-shaped sail, formed of the intestine of the walrus, sewed together with great skill in breadths of about 4 in., and weighing less than 4 lbs. The mast has a neat ivory sheave for the halyards to run on, and is placed well forward. Much taste is displayed upon the bow and stern of the *oomiak*, but the Esquimaux chiefly prides himself upon the beauty and speed of his *caiak*, in which he defies the storm, and does not hesitate to approach and give battle to the polar bear and other monsters. The Esquimaux sledge, which is drawn by dogs, is sometimes made of wood, but bone sleds are almost exclusively used at Shishvareff inlet and Regent's bay. At Regent's inlet the sled is made of a number of salmon packed together in the form of a cylinder about 7 ft. long, encased in skins taken from canoes, and well corded with thongs.

An Esquimaux Hunter.

Two of these cylinders are pressed into the shape of runners, and having been left to freeze, are secured by cross bars made of the legs of the deer or musk ox. The bottom of the runner is then covered with a mixture of moss, earth, and water, upon which is deposited about half an inch of water, which congeals in the act of application. These sleds travel more lightly than those shod with iron; but as they cease to be of service when the temperature rises above the freezing point, they are then taken to pieces, and the fish being eaten, the skins are converted into bags and the bones given to the dogs. The Esquimaux hunt with bows and arrows, spears and slings. They are fond of ornaments, and carve with much skill. Capt. Logan found on the E. coast of America models of men, women, and children, of beasts, birds, and fishes, executed in a masterly style, and with no mean

knowledge of anatomy. The ivory or walrus tusks of which they form their models are cut by continued chopping with a knife, one end of the ivory resting on a soft stone, which serves as a block. To smooth and polish the work, a gritty stone is used as a file, and kept constantly wet with saliva. Richardson represents these people as scrupulously honest toward each other, but utterly regardless of the property rights of strangers. They subsist almost exclusively upon fish and animal food, which the rigor of the climate enables them to eat raw and in large quantities. Fat of animals and fish oil constitute their chief delicacies. Mr. John Simpson, physician of the ship Plover, says their principal settlements at Point Barrow, Cape Smyth, Point Hope, and Cape Prince of Wales are inhabited during the whole year; but Wainwright inlet, Icy cape, Port Clarence, and Norton sound, the coasts of Kotzebue sound, and other settlements and huts along the coasts, are only inhabited during the winter and deserted in summer. Their commercial places are King-inng on Cape Prince of Wales, Sesualing at the mouth of the Nunatak, Nigalek at that of the river Coblille, and Nuvuak on Point Barter. Four or five Asiatic boats are engaged in the trade, and land their freight at Sesualing, where a species of fair is held toward the end of July, which is distinguished not only for its active commercial but also for its pleasant social character.—Most ethnologists class the Esquimaux with the Mongolians; Prichard, Gallatin, Duponceau, and Archbishop Taché give to them the same origin as that of the hunting tribes of North American Indians. The Moravians began missions among the Esquimaux about the middle of the last century. The missions were permanently founded in 1770, Nain being established the next year and Okkak and Hopedale soon after. They have the Gospels in Labrador Esquimaux (London, 1810-'13), and in Greenland (London, 1822). The language has no *f*, *j*, *q*, *x*, or *z*, and *b*, *d*, *g*, *l*, and *n* never begin a word.

ESQUIRE, or **Squire** (Lat. *scutifer*, old Fr. *escuyer*, a shield-bearer), originally a warrior armed with shield and javelin. Under the later Roman emperors the name was applied to soldiers to whom especially was assigned the defence of the palace and person of the emperor. The name was adopted in France, from the earliest period of the monarchy, to designate those holding the first rank in the army. In the ages of chivalry the rank of esquire followed that of valet or page, and was the last degree of apprenticeship before attaining the honor of knighthood. (See *CHIVALRY*.) In England the title of esquire strictly belongs by right of birth to the sons of younger sons of dukes and marquises; to all the sons of earls, viscounts, and barons; to the eldest sons of baronets and of knights of all the orders. The title is also given to the officers of the king's court and household; to the officers of

the army and navy down to the captain inclusive; to doctors of law, barristers, physicians, justices of the peace while in commission, and the sheriffs of counties for life. The heads of many old families are also deemed esquires by prescription. But the title is now so generally bestowed that it has lost its strict technical value. It is ordinarily used as a mark of respect in the superscription of letters in England and in the United States.

ESQUIROL, **Jean Étienne Dominique**, a French physician and philanthropist, born in Toulouse, Jan. 4, 1772, died Dec. 12, 1840. He was studying at Paris when the revolution broke out, and led him to enter the medical service of the army. In 1794 he attended the military hospital in Narbonne, and on his return to Paris he became Pinel's assistant in the *Salpêtrière*, and took at the same time an able part in the editing of Pinel's medical journal (*Médecine clinique*). In 1799 he founded a lunatic asylum, which became the model of all similar institutions afterward founded in France. He was appointed physician to the *Salpêtrière* in 1811. In 1817 he opened a course of clinical lectures, in which he pointed out the reforms needed in the treatment of lunatics, and at the same time became one of a government commission on the subject. In 1823 he was appointed inspector general of the university for the faculties of medicine, and in 1825 physician-in-chief to the royal institution for the insane at Charenton. In 1830 he was deprived of his offices in consequence of his opposition to the July revolution. He contributed many important papers to the *Encyclopédie des gens du monde*, and to the great *Dictionnaire des sciences médicales*. In 1838 he published a more elaborate work, *Des maladies mentales, considérées sous les rapports médical, hygiénique, et médico-légal* (2 vols. 8vo).

ESQUIROS, **Henri Alphonse**, a French author, born in Paris in 1814, died May 14, 1876. He published some poetry in 1834, afterward wrote in the socialist interest, and in 1840 was imprisoned for eight months on account of his heterodox description of Christ in *L'évangile du peuple*. He was an ultra-radical member of the legislative assembly from 1849 till Dec. 2, 1851, when he was banished, and went to Holland, and afterward to England. Under the amnesty of 1869 he returned to France, and was elected to the legislative body. He was prefect of the department of Bonchendu-Rhône from September to November, 1870, and in February, 1871, was elected to the national assembly, of which he was still a member in 1873. Among his works, besides several novels, are: *Les vierges martyres*, *Les vierges folles*, and *Les vierges sages* (1841-'2); *Histoire des Montagnards* (2 vols., 1847); *Les fastes populaires* (4 vols., 1851-'3); *La Néerlande et la vie hollandaise* (2 vols., 1859; English translation, "The Dutch at Home," 1861); and *L'Angleterre et la vie anglaise* (5 vols., 1869-'70; English translation by L. Wrexall,

4 vols., 1861-'3).—His wife, ADELE, has written several works, and assisted her husband in *Histoire des amants célèbres de l'antiquité*.

ESS, Heinrich Leander van, a German Roman Catholic theologian, born at Warburg, Westphalia, Feb. 25, 1770, died in Affolterbach, Oct. 13, 1847. He entered the Benedictine order in 1793, and officiated as pastor in a village from 1799 to 1813, when he became pastor and professor of theology at the university of Marburg. Conjointly with his cousin and fellow Benedictine, Karl van Ess (1770–1824), he published a new German translation of the New Testament (Brunswick, 1807; 20th ed., Sulzbach, 1830), which is highly valued. They also published *Das Alte Testament* (Nuremberg, 1819), and *Die Heilige Schrift Alten und Neuen Testaments* (Sulzbach, 1840). Heinrich made himself widely known by his endeavors to promote the reading of the Bible among the Catholics of Germany, for which purpose he prepared *Auszüge aus den heiligen Vätern* (2d ed., Sulzbach, 1822); *Pragmatica Doctorum Catholicorum Tridentini circa Vulgatam*, a prize essay (Sulzbach, 1816; German translation, Tübingen, 1824); *Was war die Bibel der ersten Christen?* (1816); *Gedanken über Bibel und Bibellesen* (1816); *Die Bibel nicht ein Buch für Priester* (1818); and *Rechtfertigung der gemischten Ehen*, a work in defence of marriages between Catholics and Protestants (1821). His views in regard to the general reading of the Bible by the people being disapproved by the German bishops and by the pope, he resigned his place at Marburg, and devoted himself to defending the position he had taken. After his death his library, comprising about 20,000 volumes, especially rich in early editions of the Bible, of the fathers, and of early theological writers, was purchased for the Union theological seminary in New York.

ESSEG. See **ESZÉK**.

ESSEN, a town of Prussia, in the province of the Rhine, near the Ruhr, 18 m. N. E. of Düsseldorf; pop. in 1846, 8,009; in 1861, 20,811; in 1871, 51,526. Few German towns have increased so rapidly during the last 20 years. Its growth is owing to its flourishing manufactures of woollen and linen goods, leather, vitriol, cast-iron and steel articles, gas apparatus, and steam engines. It has of late obtained a world-wide reputation by the famous cast-steel manufactory of Krupp, the largest in the world, employing about 10,000 persons. It is supplied with water from the Ruhr by an aqueduct 4 m. long. Until the beginning of the present century the abbess of the Benedictine nunnery (founded in 873) was the ruler of the town and the adjacent country, holding from about 1275 the rank of a princess of the empire. In 1803 the town was incorporated with Prussia; it was transferred to the grand duchy of Berg in 1808, but was regained by Prussia in 1813.

ESSEN, Hans Henrik, count, a Swedish general, born in Kafås, West Gothland, in 1755, died

July 23, 1824. He was educated in the universities of Sweden, and obtained the favor of Gustavus III. by his attainments and graceful and chivalric bearing. He accompanied him in his travels abroad, and was of great assistance in the campaign of Finland. He attended him to the masked ball where he was murdered by Anckarstroem, Essen having in vain warned him that an attempt was to be made on his life. In 1795, after having accompanied the regent duke of Södermanland and the young king Gustavus IV. to St. Petersburg, Essen was appointed governor of Stockholm. Subsequently he became governor general of Swedish Pomerania and of Rügen; and in 1807, as commander-in-chief of the Pomeranian army, he distinguished himself by his defence of Stralsund, and brought about an honorable truce with France. But the king, dissatisfied with Essen, assumed command of the army, and Essen retired from active service until the accession of the duke of Södermanland as Charles XIII., who created him a count and member of the council, and appointed him ambassador at Paris. In 1814 he marched at the head of the Swedish army against Norway; and when the two countries were united, he became governor of Norway, with the title of Norwegian field marshal and chancellor of the university of Christiania. In 1817 he was made governor general of Scania.

ESSENCES. See **ESSENTIAL OILS**.

ESSENEES, a Jewish sect, not mentioned in the Jewish or Christian Scriptures, and concerning whom the only original sources of information are passages in the works of Josephus and Philo, both of whom lived about the time when the Essenes had reached their highest development. Philo, a disciple of the Alexandrian school of philosophy, attracted by their mystical and speculative turn, gives the fullest information concerning their doctrines. Josephus, who lived in Palestine where the community flourished, and according to his own statement was in early life a member of it, treats of them particularly in their outward relations. The Essenes first appear in history in the latter half of the 2d century B. C., as a society of piously disposed men, who in the solitudes on the western side of the Dead sea sought a retreat from the corruptions and conflicts of the world. They lived an austere life, held their property in common, wore a white robe, prayed and meditated continually, made frequent ablutions, for the most part renounced marriage, and often practised medicine. They sacrificed no animals, and instead of going themselves to worship in the temple of Jerusalem, they sent their offerings. Contemning logic, metaphysics, and even physical science, as useless, they gave their attention only to ethics, recognized no other authority than their own sacred books, and taught the equality of men and the entire supremacy of destiny. Their number at the beginning of the Christian era was about 4,000. After the destruction of

Jerusalem they disappeared from history. In the obscurity which covers their origin and the specialties of their conduct and ideas, they have been variously compared to the old Hebrew schools of prophets, the Greek Pythagoreans and Stoics, the Christian monks, and the modern Quakers. De Quincey has sought to identify them with the early Christians, who, surrounded by dangers, assumed the name and mode of life of the Essenes as a disguise, alike impenetrable to Jewish or Roman enemies, and to timid or treacherous brethren. Monographs on the Essenes have been written by Bellermann, who identifies them with the kindred Jewish sect of the Therapeutæ in Egypt (Berlin, 1821), Saner (Breslau, 1829), and Leutbecher (Amsterdam, 1857).

ESSENTIAL OILS (called also volatile oils, and distilled oils), oily products derived from plants, generally by distilling portions of them with water. The aqueous vapor which passes over carries with it the vapor of these oils, though their boiling point is often higher than that of water. They condense together in the receiver of the still, the oil commonly floating upon the water, sometimes sinking beneath it. A portion appears to be taken up by the water, giving to it the peculiar odor and properties of the oil in a less degree. This is called medicated and perfumed water. The oils contain in a concentrated form the fragrance and essential properties of the plants, or of the portion of them employed, and when kept dissolved in alcohol constitute the essences. They may sometimes be obtained by expressing the parts containing them, as the rind of the orange and lemon; and sometimes they are so evanescent as to escape in the ordinary mode of securing them by distillation with water. The method then adopted, as in securing the oil in which lies the delicate fragrance of the tuberose, narcissus, jasmine, &c., is to arrange the flowers in layers with cotton imbued with some fixed and inodorous vegetable oil. This gradually absorbs the volatile oil of the flowers, and when the cotton is digested in alcohol, the volatile oil is taken up by this fluid, and an essence is obtained. In some cases it may be separated also by distilling the cotton with water or alcohol. The odor of the oil is often less agreeable than that of the plant, which is probably owing to its greater concentration, as by dilution it is made more pleasant. The oils are often colored some shade of red, brown, yellow, green, or blue, but this is not always fixed. Their taste is hot and pungent, but made pleasantly aromatic by dilution. Some are poisonous. They burn with a bright and often smoky flame. The feeling of them upon the hand is not greasy like that of the fixed oils, but rough, and a cork moistened with them grates harshly when turned in the phial. Their specific gravity varies from 0.847 to 1.17. They boil at various degrees, some at 320° F., and a few others require a higher temperature. Exposed to the air and light at ordinary tem-

peratures, they absorb oxygen, become darker and thicker, and are finally changed into resin, sometimes into acid compounds. Most of them consist, like the fixed oils, of a thin fluid and a solid product, which may be separated at a low temperature by compressing the substance between folds of paper. The camphor-like product called by Berzelius stearoptene is retained within the folds, while the oily fluid called elaioptene passes through. The ultimate analysis of the essential oils affords in most instances carbon, hydrogen, and oxygen. Some prove to be hydrocarbons, containing no oxygen; and in these the proportion of carbon is between 88 and 89 per cent., and of hydrogen between 11 and 12 per cent., which would be expressed by the formula $C_{11}H_{14}$. Nitrogen is found as a constituent of some of them, and sulphur is met with in the oils of mustard and of horse radish.—The agreeable odors retained by many of the oils cause them to be largely used in perfumery. Their medicinal properties also render many of them valuable agents. These properties depend upon the plants from which they are derived. Most of them are aromatics and stimulants. They are chiefly used in medicine to render other articles grateful to the taste or acceptable to the stomach, though some of them are employed for other purposes, as when the oil of cubeb is given to obtain the physiological actions of the berry from which it is derived. For a more detailed account of the remedial use of these oils the reader is referred to the articles upon the plants that yield them. Their dose is commonly only a few drops, which may be administered on a lump of sugar, or triturated with a dozen times their weight of sugar, and then mixed with water. Some are largely employed in the manufacture of paints and varnishes, some in printing calico, and some have been used for illuminating purposes.—Essential oils are frequently adulterated. The presence of fixed oils added to them for this purpose may be detected by the greasy stain left upon paper moistened with the liquid and exposed to heat sufficient to drive off the volatile oil. Alcohol is detected by various tests, as by adding water and agitating the mixture, which becomes milky if alcohol is present; and the bulk of the oil is reduced as the fluids separate on standing, by the alcohol leaving it and going with the water. A piece of potassium as large as the head of a pin will remain nearly 15 minutes in contact with a dozen drops of pure oil without change; but if it disappears in five minutes, the oil contains at least 4 per cent. of alcohol; if it disappears in one minute, it contains at least 25 per cent. Fused chloride of calcium is also used to abstract alcohol from the oils. When the high-priced oils are adulterated with the cheaper kinds, a thorough practical acquaintance with the physical properties of the oils can alone serve to detect the imposition. The odor of oil of turpentine when used for this purpose is concealed until the oil is dissolved in alcohol,

and water is added, when both the odor and flavor are easily recognized. The oils require to be kept in small bottles entirely filled, well stopped, and excluded from the light.—By recently devised chemical processes artificial essences imitating the flavor of various choice fruits are prepared from substances which would seem entirely unfitted for producing such results. Thus butyric acid, a product of butter or putrid cheese, being converted into an ether, cannot be distinguished from that prepared from the pineapple, and may be used equally well with the latter to produce the celebrated pineapple rum. The fetid fusel oil, separated from brandy and whiskey in rectifying these liquors, produces, when distilled with sulphuric acid and acetate of potash, an essence of pears; and if for the acetate of potash bichromate of potash be substituted, the product is an essence of apples. By similar methods a variety of other flavors are obtained; and though when concentrated they are acrid, they become very agreeable when used as flavoring in proportions of a drop to an ounce or two ounces. Some of the choicest perfumes are by similar chemical processes prepared from substances which seem strangely foreign to their nature.

ESSEQUIBO. I. The principal river of British Guiana, rises in the Acuray mountains near the S. limit of the country, lat. $1^{\circ} 30' N.$, lon. $57^{\circ} 11' W.$, traverses it in an almost northerly direction, and falls into the Atlantic by an estuary 30 m. wide at its mouth, about lat. $7^{\circ} N.$, lon. $58^{\circ} 30' W.$ Its course is interrupted by numerous cataracts, the principal of which is that called King William's, about lat. $3^{\circ} 14' N.$, where navigation ceases. The upper part of its course is extremely tortuous; but below lat. 5° it bends northward, and holds that direction to its embouchure. The last of the more important rapids occurs about 60 m. from the mouth of the river, and mark the limits of the tidal movement. There are many considerable islands in the river and at its mouth. The entrance is rendered dangerous by a number of sand banks, like a succession of bars lying crosswise in the channel. The whole course of the stream is perhaps 450 m., mainly through a region of great natural beauty. The largest of the numerous tributaries of the Essequibo are the Rupununi, about 250 m. long; the Cuyuni, or Cuyuwini, a river of great magnitude flowing E. from the Venezuelan mountains and forming its junction near the S. part of the estuary through a mouth 1 m. wide; and the Putaro, in which is the stupendous cataract of Kaietur. (See GUIANA.) Numerous excellent fish are found in the Essequibo, the most remarkable of which is the formidable *peri* or *oma*, 2 ft. long, and armed with strong teeth; also large numbers of manatees or sea cows, of gigantic size, and in most respects distinct from those of the West Indies, and electric eels. II. A part of the territory of British Guiana, now united into one county with Demerara. (See GUIANA.)

ESSEX, the name of five counties in the United States. I. A N. E. county of Vermont, bounded N. by Canada, and E. by the Connecticut river, which separates it from New Hampshire; area, 790 sq. m.; pop. in 1870, 6,811. The surface is rough and mountainous, with numerous small lakes and ponds scattered over it. The soil is well watered, but, except in the valley of the Connecticut, not remarkable for fertility. It is traversed by the Grand Trunk railway from Portland to Montreal. The chief productions in 1870 were 13,613 bushels of Indian corn, 107,589 of oats, 229,941 of potatoes, 18,809 tons of hay, 233,285 lbs. of butter, 24,132 of wool, and 178,188 of maple sugar. There were 1,383 horses, 2,543 milch cows, 4,341 other cattle, and 5,716 sheep; 2 flour mills, 27 saw mills, and 6 starch factories. Capital, Guildhall. II. A N. E. county of Massachusetts, bounded N. by New Hampshire, and E. and S. E. by the Atlantic and Massachusetts bay, and traversed by the Ipswich and Merrimack rivers, the latter of which is navigable as far as Haverhill by vessels of 200 tons; area, about 500 sq. m.; pop. in 1870, 200,843. The surface is generally rough and the soil hard and rocky; but it is carefully cultivated, and in many places has been rendered very productive. The chief sources of wealth are commerce and the fisheries, for the prosecution of which the long line of seacoast broken by beautiful bays offers great advantages. The fishing interest is more extensive here than anywhere else in the United States. The interior towns are extensively engaged in the manufacture of leather, shoes, and cotton. The Boston and Maine and the Eastern railroads, with several branches, pass through the county. The chief productions in 1870 were 9,256 bushels of rye, 94,033 of Indian corn, 27,427 of oats, 20,653 of barley, 310,807 of potatoes, 50,299 tons of hay, and 335,885 lbs. of butter. There were 3,177 horses, 9,076 milch cows, 5,636 other cattle, 1,254 sheep, and 4,938 swine. There were 2,821 manufacturing establishments; capital employed, \$29,777,160; value of products, \$96,990,868. Those most important were 445 of boots and shoes, 111 of boot and shoe findings, 12 of cotton goods, 21 of woollen and 13 of worsted goods, 79 of carriages and wagons, 13 of hats and caps, 2 establishments for printing cotton and woollen goods, 6 for bleaching and dyeing, 24 for preparing morocco, 76 for currying leather, 59 tanneries, 14 flour mills, 34 machine shops, 5 paper mills, 43 yards for building and repairing ships, and 10 manufactories of cordage and twine. County towns, Salem, Lawrence, and Newburyport. III. A N. E. county of New York, bordering on Lake Champlain, and bounded N. partly by the river Au Sable; area, 1,656 sq. m.; pop. in 1870, 29,042. The country along the lake shore is tolerably level, but the N. W. part is occupied by the Adirondack mountains, which are covered with thick for-

ests. Tahawus or Mt. Marcy, 5,337 ft. high, is the principal summit, and the highest in the state. The county is drained by the head waters of Hudson river, and by Bouquet and Schroon rivers, which afford valuable water power, and has numerous small but picturesque lakes. The soil is well watered, and there are immense beds of magnetic iron ore. The chief productions in 1870 were 49,850 bushels of wheat, 100,662 of Indian corn, 317,790 of oats, 49,184 of buckwheat, 406,122 of potatoes, 60,211 tons of hay, 993,974 lbs. of butter, 260,800 of wool, and 64,654 of maple sugar. There were 5,664 horses, 8,026 milch cows, 9,012 other cattle, 62,664 sheep, and 2,958 swine; 12 manufactories of carriages and wagons, 6 of charcoal, 3 of furniture, 20 of iron in various forms, 1 of nails and spikes, 1 of marble and stone work, 2 of sashes, doors, and blinds, 3 of starch, 2 of woollen goods, 7 tanneries, 17 saw mills, and 8 flour mills. Capital, Elizabethtown. **IV.** A. N. E. county of New Jersey, bounded E. by Passaic river and Newark bay, and W. by Passaic river; area, 200 sq. m.; pop. in 1870, 143,839. The surface is generally level, but there are two elevated ridges in the W. part, known as First and Second mountains. Much of the soil is highly fertile. It is traversed by the New Jersey, the Newark, and Bloomfield, and the Morris and Essex railroads, and the Morris canal. The chief productions in 1870 were 7,579 bushels of wheat, 6,249 of rye, 66,192 of Indian corn, 22,107 of oats, 73,060 of potatoes, 11,328 tons of hay, and 125,232 lbs. of butter. There were 1,426 horses, 2,858 milch cows, 1,248 other cattle, and 1,164 swine. There is a large number of manufacturing establishments, chiefly in Newark, the capital. **V.** An E. county of Virginia, bounded N. E. by Rappahannock river; area, about 300 sq. m.; pop. in 1870, 9,927, of whom 6,650 were colored. It has an uneven surface in the W. part; the soil is generally sandy, of little natural fertility, but greatly improved by the use of marl, guano, and lime. The chief productions in 1870 were 47,577 bushels of wheat, 264,605 of Indian corn, and 14,757 of oats. There were 624 horses, 3,250 other cattle, and 3,055 swine. Capital, Tappahannock.

ESSEX, a S. W. county of Ontario, Canada, comprising a peninsula between Lake Erie and Lake St. Clair; area, 700 sq. m.; pop. in 1871, 32,697. It is separated from Michigan by the Detroit river, and is traversed by the Great Western railway. Capital, Sandwich.

ESSEX, a county on the E. coast of England, bounded S. by the river Thames, and bordering on Suffolk, Cambridgeshire, Hertfordshire, Middlesex, and Kent; greatest length from S. W. to N. E., 60 m.; greatest breadth, 45 m.; area, 1,657 sq. m.; pop. in 1871, 466,427. Except in the N. W., where there is a continual succession of hill and dale, the surface is nearly level, and in the S. and E. is partly occupied by large marshes. The soil is fertile, and the

farms are accounted among the best in the kingdom. Wheat is the staple production. The county is famous for its veal. Valuable fisheries and oyster beds furnish employment to the inhabitants of the coast and adjacent islands. Silk is manufactured, and straw plait is made for London use. The principal channels of communication are the Eastern Counties railway and its various connections, and the rivers Thames, Lea, Stort, Chelmer, Stour, and Colne. Chelmsford, the county town, Colchester, Harwich, and Maldon are the chief towns.

ESSEX, Earls of. **I.** See CROMWELL, THOMAS. **II.** Walter Devereux, first earl of Essex of his name, born in Carmarthenshire, Wales, about 1540, died in Dublin, Sept. 22, 1576. He succeeded his grandfather early in the title of Viscount Hereford, and recommended himself to Queen Elizabeth by his bravery in suppressing the rebellion of the earls of Northumberland and Westmoreland in 1569. For this service he received the garter and the earldom of Essex. In 1573 he undertook an expedition, in company with other noblemen and gentlemen, for subduing and colonizing a portion of Ulster in Ireland; but in its prosecution he was subjected to many trials and disappointments. He was obliged to make peace with O'Neal, when, by continuing the war, he had the fairest prospects of driving him out of the country. He was also required to give up his command just as he had almost expelled the invading Scots from the western islands of his territory. Harassed with his difficulties, he retired to England, but was again induced to return, with the title of earl marshal of Ireland and the promise of support and assistance. As these promises were but poorly kept, he was overcome with grief, and the agitation of his mind threw him into a fatal dysentery. There was suspicion of poison, which was not diminished by the marriage, soon after, of his countess to the earl of Leicester. **III.** Robert Devereux, son of the preceding, second earl, born at Netherwood, Herefordshire, Nov. 10, 1567, executed Feb. 25, 1601. He succeeded to his title in his 10th year, and in 1577 was sent by his guardian Lord Burleigh to Trinity college, Cambridge, where he took the degree of master of arts. He appeared at court in his 17th year, and soon captivated Elizabeth. In 1585 he accompanied the earl of Leicester to Holland, and displayed his personal courage in the battle of Zutphen. In 1587 he was appointed master of the horse, and in the following year the queen created him captain general of the cavalry, and conferred on him the honor of the garter. He succeeded Leicester as prime favorite, and his attendance was constantly required at court. In 1589, when an expedition against Portugal was undertaken by Drake and Norris, Essex secretly followed the armament, and joined it on the coast of Portugal. Though he had departed without the permission of the queen, he was quickly reconciled with her after his return, and at once assumed a

superiority over Sir Walter Raleigh and Sir Charles Blount, the rival competitors for royal favor. He was challenged by Blount and wounded in the knee, and the queen is said to have expressed her gratification that some one had taken him in hand, as otherwise there would be no ruling him. In 1590 he married the daughter of Sir Francis Walsingham, the widow of Sir Philip Sidney, and in the following year had command of a fruitless expedition in Brittany against the Spaniards. When in 1596 alarm was excited by the hostile preparations in the Spanish harbors, he was joined with Lord Admiral Howard in command of the expedition against Cadiz. The intrigues of the Cecils caused him to be coolly received on his return; but he quickly recovered favor. Two subsequent expeditions which he conducted against Spanish shipping met with little success. The queen received him with reproaches, and he retired to Wanstead; nor would he be pacified by her acknowledgment that the charges against him were unfounded, but after a long negotiation he accepted the office of hereditary earl marshal as indemnity for the promotion that had been given to his rivals. In 1598 he quarrelled with the queen about the appointment of deputy in Ireland, and when she boxed him on the ear for turning his back to her in presence of her ministers, he swore that he would not endure such an affront even from Henry VIII. himself, and withdrew from court. Only a formal reconciliation was ever effected. In 1599 the province of Ulster was in rebellion, and Essex accepted the lord-lieutenancy of Ireland. His campaign resulted only in a temporary armistice. He returned in haste, and retired from his first audience with a cheerful countenance, but was immediately ordered to consider himself a prisoner in his own house. After months of hesitation, he at length conceived the plan of forcibly banishing his enemies from her majesty's council. At the head of a force of about 300 men he made his way into London, but was disappointed in expecting the people to rise in his favor; he took refuge in Essex house, where he was besieged and forced to surrender. He was committed to the tower, tried for treason, condemned, and executed, the queen reluctantly signing the warrant. He was an accomplished scholar, and a patron of literature. He erected a monument to Spenser, gave an estate to Bacon, and was the friend of Wotton and other men of learning. **IV. Robert Devereux**, son of the preceding, third earl, born in London in 1592, died there, Sept. 14, 1646. He succeeded to his title in 1603, and in his 15th year was married to Lady Frances Howard, who was a year younger. He proceeded to the university and thence to the continent, while his wife remained at court, and numbered Prince Henry and Rochester (afterward earl of Somerset) among her admirers. In 1613 she obtained a divorce, and was soon after married to Rochester. Essex led a solitary life in his country

house, till in 1620 he raised a troop and served in the wars of the Netherlands. He was engaged in several campaigns abroad, and as vice admiral commanded a fruitless expedition sent by England against Spain. His second marriage also resulted unhappily and in a divorce. At the outbreak of the civil war he was appointed lord general by the parliament, laid siege to Portsmouth, and was proclaimed a traitor by Charles. He fought against the king at Edgehill (1642), captured Reading (1643), and advanced into Cornwall, but met with a succession of disasters which forced his army to capitulate. He escaped in a boat to Plymouth, and went to London, where a parliamentary deputation waited on him in honor of his faithful services. He again raised a corps, but ill health soon obliged him to quit his command. As early as 1644 he suspected Cromwell of a design to erect a new government. He therefore urged his impeachment before the house of lords, and Cromwell took revenge by proposing the "self-denying ordinance," by which members of both houses were excluded from all offices, whether civil or military. This measure having passed, Essex ceased to be a parliamentary general, but for his services £10,000 per annum was voted to him out of the sequestered estates of the loyalists.—The title expired with him, and was revived in 1661 in favor of Arthur, second Baron Capel, in whose family it still remains.

ESSLING. See ASPERN and ESSLING.

ESSLINGEN, a town of Württemberg, Germany, on the Neckar, 9 m. S. E. of Stuttgart, on the Ulm railway; pop. in 1871, 17,941. It is a place of great antiquity, and has old walls flanked with towers, and the old Berfried castle. The Frauenkirche is an admirable specimen of Gothic architecture of the 15th century, and is attended both by Protestants and Roman Catholics. The church of St. Dionysius was built in the Romanesque style in the 13th century, and enlarged in the 15th. There are several superior educational institutions, and a school for the deaf and dumb, and adjoining the town is the water-cure establishment of Kennenburg for the relief of the insane. Esslingen is important for its trade and industry. The fruit market is especially renowned; the culture of the vine is extensive, and the celebrated Esslingen champagne is the oldest sparkling wine in Germany. Railway locomotives are exported to many parts of the world. There are many manufactories of cloth, cotton, and woollen goods, optical and physical instruments, &c.—Esslingen became a free imperial city under the Hohenstaufen. The Swabian league was founded here in 1488. Its prosperity, increased after the reformation, but impaired by the thirty years' war and by intestine commotions, has been revived since 1801, when it became part of Württemberg.

ESTAING, Charles Hector, count d', a French naval officer, born at the château of Ruvel, Auvergne, in 1729, executed in Paris, April 28,

1794. He entered the military service, and in 1758 accompanied the count de Lally in his expedition to the East Indies, with the rank of brigadier general. He was taken prisoner at the siege of Madras, but was released on parole, and at once took command of two French men-of-war, and inflicted great damage upon the English in the East. On his return to France, in 1760, he was captured near Lorient, and thrown into prison at Portsmouth, the English asserting that he had resumed active service before he was authorized by the terms of his exchange, but was released, and in 1763 was appointed lieutenant general in the navy. In 1778 he was sent to the United States in command of twelve ships of the line and four frigates. He landed Gérard, the first ambassador from France to the United States, and then came to anchor off New York. An attack upon the city had been projected, but it was abandoned, the pilots thinking that the largest of the French vessels could not be taken over the bar. A joint attack upon Newport by land and sea was next proposed. D'Estaing sailed for Narragansett bay, entered Newport harbor, and compelled the British to burn or sink six frigates which lay there. A few days afterward the continentals, under Greene and Lafayette, landed on the island, and expected to be joined by 4,000 men from the French fleet. But D'Estaing had put to sea, and engaged Lord Howe, who had come to the relief of Newport. The fleets being separated by a storm, D'Estaing took his shattered vessels to Boston to refit, and the attack upon Newport was given up. In November he sailed for the West Indies, where he attempted without success to take the island of St. Lucia, but took St. Vincent and Grenada. He also forced the British admiral who had come to the relief of Grenada to retire. He then sailed for the coast of Georgia with 22 ships of the line. His troops coöperated with those of the Americans, Oct. 9, 1779, in an attack upon Savannah. Both the American column and the French were repulsed, D'Estaing being wounded and Pulaski killed in the assault. D'Estaing returned to France in 1780. He declared himself in favor of national reforms, and was elected in 1787 to the assembly of notables, appointed commandant of the national guard, and chosen admiral in 1792 by the legislative assembly. But he cherished a regard for the royal family, and wrote friendly letters to Marie Antoinette which came to the knowledge of the revolutionary authorities; and he was arrested and imprisoned. On the trial of Marie Antoinette in 1793 he testified in her favor. He was himself brought to trial in the following year, and condemned to death. He wrote a poem entitled *Le rêve*, a tragedy, and a book on the colonies.

ESTATE (Lat. *status*), in law, a term usually expressing an interest in lands, though in a general sense it is applied to both real and personal property, as we sometimes see in wills and the like. But when used with a discrimi-

native signification to designate the nature and limit of the interest, it properly relates to lands only. There are several classes of estates. 1. An estate of inheritance, which is sometimes expressed by the term fee. Thus when we say a man has the fee of lands, it is meant that he has an inheritable estate; and in the United States, where there is no limitation to particular heirs, it is understood to be the entire proprietorship of the lands. But in England there are estates of inheritance in fee simple and fee tail, the former being an estate which descends to a man's general heirs, the latter being limited to certain specified heirs, as for instance to a man's issue male or female, or to the heirs of his body begotten of a certain wife. By such limitations, although the estate descends to the particular heirs, yet failing them it reverts to the grantor or supposed original proprietor, instead of descending to a man's general heirs; and so far there is an obstruction in the enjoyment of the estate, because a man is perpetuated in and represented by his heirs. In this sense a fee simple is deemed an absolute ownership, in distinction from a fee tail, which is limited in descent. Another distinction was more important, viz.: that while the former could be conveyed or devised, the latter in theory could not be, yet practically it could be alienated by a particular form of proceeding called a common recovery. Yet a fee simple is not necessarily the entire proprietorship, for it may be subject to encumbrances by mortgage or judgment and otherwise; and smaller estates, as a lease for years, may be carved out of it, though in such a case it would be more proper to call the principal estate a fee simple in reversion or remainder. There are also qualified or determinable estates of inheritance, by which is meant that the estate may be determined by some contingency, and yet the contingency may never happen, and therefore by possibility the estate will be perpetual. The illustrations of this species of inheritance are for the most part hypothetical, as to a man and his heirs so long as St. Paul's church shall stand. Sometimes the qualification is residence in a particular place. Or again, there may be a restriction that the person taking the estate shall not marry, an instance of which we have in the case of a devise by a man to his wife on condition that she shall continue a widow. When by the limitation an estate is to last till a certain event, there is until the event happen an inheritance subject to being determined; though if the event become impossible, then the estate is converted into a fee simple absolute. A conveyance by the owner of a determinable fee will of course be subject to the disqualification or contingency upon which the estate depends. It may be a question, in the case of a limitation to a man and his heirs so long as they reside in a certain place, what the effect of alienation would be; but probably the same rule would apply, viz.: that it would be valid to the extent of the right which the grantee him-

self had, but would be defeated by a breach of the condition. If this would be inconsistent with the nature of the estate, the restriction would, it may be presumed, be void under the statutory rule which has been adopted in the state of New York, whereby the power of alienation cannot be suspended by any limitation or condition whatever for a longer period than two lives in being at the creation of the estate. II. An estate for life may be either by express grant or by operation of law. Of the latter kind are dower and curtesy, the respective interests of the wife and husband, each in the lands of the other, in case of survivorship. Estates for life as well as inheritance are included in the common denomination of freehold (*liberum tenementum*); which term seems to have been derived from the ancient mode of conveyance, which was by livery of seisin, that is, delivery of possession according to the form of feudal investiture. Other estates which were of an inferior nature could be transferred without this formality. It was chiefly as a distinction from copyhold estates that the term was used. The copyhold was originally an estate at the mere will of the lord, but became established by prescription, the evidence of which was in the rolls of the courts baron, whence the estate was said to be held by copy of court roll; and although it thus became independent of the will of the lord, it was still deemed a base tenure, and the form of conveyance was by surrender to the lord, and a new grant by him to the alienee, admitting him to be tenant of the copyhold upon the same terms by which the estate had been formerly held. An estate for life may be either for the life of the tenant himself or of another person. The latter is usually designated as an estate *par autre vie*. III. Estates less than freehold are for a term of years, or at will, or by sufferance. The first is for a definite period; but whatever may be the length of the period, even if it should be a thousand years, it is still inferior to a freehold, and is classed in law with chattel interests. Thus, on the death of a tenant, his lease is included with the personal property to be administered as assets, instead of going to the heir. An estate at will was when lands were occupied by the tenant with consent of the landlord, but without any agreement as to the time the tenant shall be permitted to remain. It can hardly be said to exist at present, as the courts now hold a tenancy where no certain term is agreed upon to be from year to year, and reasonable notice must be given of the intention to terminate it. The circumstance that distinguishes the two kinds of tenancy is the reservation of a certain rent, which may be either by express agreement, or by implication from the receipt of rent. If a certain rent is payable, it constitutes an estate from year to year; but if neither rent nor time of occupation is specified, it is a tenancy at will. An estate by sufferance is where the tenant has been in possession by lawful title, but wrong-

fully holds over after the determination of his interest. In such a case the tenant holds by the mere laches of the landlord, and is subject to being turned out by summary proceedings. But any act of the landlord affirming the wrongful holding, as receipt of rent, would convert the naked occupancy into a tenancy from year to year, and is then determinable only at the end of the year. The English statute of frauds (29 Charles II.), which has been generally reenacted in the United States, requires leases for a term of more than one year to be in writing; and in the state of New York and many other states a lease for a term exceeding three years must be recorded, or it will be inoperative against subsequent *bona fide* purchasers. Another distinction in the nature of estates has reference to the time when the right is reducible to possession. The right may exist prospectively, and it is then termed an estate in expectancy. It is of two kinds: one created by the act of parties, and called a remainder; the other by operation of law, and called a reversion. An estate in remainder is what remains after a particular estate, either for years or life, to take effect in possession immediately after such estate, and must be created at the same time, though limited to commence in possession at a future time. Thus if a life estate be granted to A, with remainder to B for life, and remainder to C in fee, here are two remainders to commence in future, and the whole property constitutes but one estate. Yet in ordinary phraseology, where there is but one remainder including the whole residue of the estate, the fee is said to be in the person to whom such limitation is made. An estate in reversion is the residue of an estate left in the grantor or his heirs or in the heirs of a testator after the determination of a particular estate granted or devised. The estate reverts by operation of law, and a reservation to the grantor by the deed would have no effect, being only what the law itself prescribes. A contingent remainder is when the limitation depends upon a contingency which is uncertain or may not occur till after the determination of the particular estate; though it is held that such contingency must not be a remote possibility, as if the limitation should be to the heirs of a child not yet born. A single illustration of this kind of estate will be sufficient. If a grant be made to A for life, with remainder to the heirs of B, and B should survive A, inasmuch as he cannot have heirs while living, the remainder would fail; but if the limitation be to A and B during their joint lives, with remainder to the survivor, here the remainder will take effect, though it is uncertain as to the person who will have the benefit of it. An executory devise is a disposition of an estate by will which would not be valid if made by deed, as a limitation of a contingent remainder. The distinction is that the remainder must take effect immediately upon the determination of the particular estate or not at all; whereas an execu-

tory devise is good without a particular estate to support it. Thus if a devise be made to A, to take effect on his marriage, in this case until such marriage the fee descends to the heir at law, subject to being divested by the performance of the condition. There is still another distinction of estates growing out of the nature of the possession, under which head are classed joint tenancy, tenancy in common, and coparcenary. The last of these, which is a descent of an inheritance to female heirs, in which case they take an equal interest in the entire estate, but without being subject to the rule which applied to joint tenancy as to the right of the survivor to the whole, does not exist in the United States, at least is not distinguishable from a tenancy in common. So joint tenancy, the peculiar feature of which is that the whole estate vests in the survivor, has been abolished in this country, except in respect to executors and other trustees and mortgagees, and except also when it is expressly declared in the deed or will creating the estate that it is to be held in joint tenancy. In all other cases, where there is a possession of lands by several persons without any separation into specific parts, it is a tenancy in common; and it is not necessary that they should all hold by the same title, or have an equal interest; it is sufficient if each has an interest, and that it is undivided. Such an interest can be conveyed or devised, the same as property held in severalty, and partition may be compelled by either party on application to a competent court. Various equitable interests in lands will be discussed in the article TRUSTS. —We have thus far considered estates of a corporeal nature only; but there are also incorporeal estates, such as rents, easements, &c. But the general principles applicable to the one class will also apply to the other; and whatever there may be peculiar to any particular species of incorporeal estate will be treated under the appropriate head.

ESTE (anc. *Ateste*), a town of N. Italy, in the province and 16 m. S. W. of the city of Padua, beautifully situated at the foot of Monte Murale or Cero, at the S. extremity of the Euganean hills; pop. about 10,000. It is a mediæval town, with arched houses, and famous for the castle of Este, known as *la rocca*, consisting of a donjon tower with frowning embrasures and battlements, and standing on an elevation upon the site of the original castle of the celebrated house of Este. The church of San Martino, of modern interior and antique exterior, has a belfry which inclines nearly as much as the leaning tower of Pisa. The manufactures of Este include silks, earthenware, majolica, and saltpetre, and there are many whetstone quarries in the neighborhood. The railway station is 3 m. outside the town. The vicinity of Este is celebrated for its picturesque scenery. The ancient Ateste was a municipal town as early as 136 B. C.

ESTE, a princely house of Italy deriving its name from the town of Este. Alberto Azzo II.

of this family (born in 996, died in 1097) married first Kunitza or Kunigunde, a princess of the Bavarian house of Guelph or Welf. His son by this marriage, Guelfo IV., inherited the possessions of his mother's brother, Guelph or Welf III. From him are descended the houses of Brunswick and Hanover (known also by the name of Este-Guelph) and the sovereigns of Great Britain. Alberto Azzo married for his second wife Garsenda, countess of Maine in France. He had by her two sons, Folco and Hugo. Folco inherited the Italian estates of his father, and transmitted them to his son Obizzo, under whom the foundation was laid for the dominion of the house of Este over Ferrara. This was accomplished by carrying off Marchesella, the sole descendant of the Adelardi family, who had been betrothed to one of the Ghibelline family of Taurello, and compelling her to marry Azzo of Este, the son of Obizzo. The Adelardi family had been the popular leaders of the Guelphs in Ferrara, and the marriage secured to the house of Este the possession of Ferrara and other Italian towns. Azzo VI. (1170-1212) was placed in 1208 at the head of the government of Ferrara, with power to appoint a successor, and was the leader of the Guelphs against Ezzelino, the champion of the Ghibellines. Azzo VII. (1205-64) defeated Ezzelino, and was hailed as the saviour of Lombardy. Borso, another prince of the house of Este, received in 1452, from the emperor Frederick III., the titles of duke of Modena and Reggio and count of Rovigo, and from Pope Paul II. in 1471 the title of duke of Ferrara. He was distinguished for his patronage of arts and letters. He was succeeded by his brother Ercole I., who was also a patron of literature. Alfonso I., the son of Ercole, married Lucrezia Borgia. The court of Alfonso II., who was the last legitimate prince of the house of Este, was renowned for its splendor. His name, as well as those of his sisters, Lucrezia and Eleonora, are associated with the misfortunes of Tasso. After the death of Alfonso II. (1597) Ferrara was seized by Pope Clement VIII. as a papal fief. The duchies of Modena and Reggio remained in the family, but in 1797 were taken by Bonaparte from its representative, Ercole Rinaldo, and annexed to the Cisalpine republic. The daughter of the latter, Maria Beatrice, married the archduke Ferdinand, third son of Francis I. of Austria.—The name of Este was adopted by the children of the duke of Sussex, sixth son of George III. of England, and Lady Augusta Murray. The marriage of the duke of Sussex with Lady Augusta was held by the English prerogative court to have been in violation of the royal marriage act, and was annulled. Augusta Emma d'Este, one of the children of the marriage, married in 1845 Sir Thomas Wilde, afterward Baron Truro. Augustus Frederick d'Este, the other child, a colonel in the army, endeavored without success to obtain recognition as one of the royal family.

ESTELLA, a city of Navarre, Spain, on the left bank of the Ega, about 25 m. S. W. of Pamplona; pop. about 6,000. It is situated in a beautiful valley surrounded by hills and planted with vines, olives, and other trees. It has excellent streets and fine squares, and contains an ancient castle, a number of churches, and many public institutions, including a college and an academy of music. There are manufactures of woollen, linen, and silk goods, oil, wine, brandy, earthenware, and leather, and an active trade. Don Carlos, the first pretender of this name, whose headquarters were for a long time in this locality, was proclaimed king here in November, 1833; and in 1839, when he fled to France, a number of his officers were summarily executed at Estella. In the summer of 1873 the Carlists again occupied the town, but on Oct. 5 were compelled to evacuate it by the government troops under Gen. Moriones.

ESTEPA, a town of Spain, in the province and about 60 m. E. S. E. of the city of Seville, on the N. side of Mount Francisco; pop. about 7,000. It is tolerably well built, with some large and many small and steep streets, and a number of squares. The church of Santa Maria la Mayor is a Gothic building of alleged Moorish origin. There is an ancient feudal fortress, which was once deemed impregnable on account of its situation on the summit of the mountain which overhangs the town. Coarse cloths and other articles are manufactured, and there are many oil mills.—Estepa is supposed to occupy the site of the ancient Astapa, whose inhabitants in the second Punic war destroyed themselves and their city rather than fall into the hands of the Romans.

ESTEPONA, a town of Spain, on the Mediterranean, in the province of Malaga, 25 m. N. E. of Gibraltar; pop. about 9,000. It contains the ruins of an ancient castle and an unusually large number of boarding and day schools. The parish church, built in 1474, is a fine building. The inhabitants are chiefly engaged in the herring fishery and maritime enterprises.

ESTERHÁZY (**ESTERHÁZY DE GALÁNTA**; Hun. *Eszerházy*), a family of Hungarian magnates, distinguished for their wealth, of whom the first authentic record is dated in 1238. This record mentions the division of the estates of Solomon of Estoras between his two sons, who assumed from their lands the names of Zerhazy and Illyészahy. Francis Zerhazy was knighted in 1584, and adopted the name of Esterházy of Galánta. His sons Gabriel, Daniel, Paul, and Nicholas became the founders of four lines, of which the first became extinct in 1670, while the others have come down to our day. Of these the lines of Old Zólyom or Altsohl and Csesznek were created counts in 1683, and the line of Fraknó or Forchenstein as early as 1626, through its representative Nicholas Esterházy of Fraknó, who died with the rank of palatine and field marshal in 1645. The two younger sons of the last named, Paul and Francis, be-

came the founders of the line of counts and of the line of princes of the house of Esterházy-Fraknó. The line of counts separated into three branches, all of which are still represented, as are also the Old Zólyom and Csesznek lines. The princely main branch of the house of Esterházy was founded by Paul IV. in 1635, who was created prince in 1687 in reward of his services as general of cavalry and palatine of Hungary. He died in 1713. He was succeeded by Prince Michael, who died in 1721, leaving no male issue. The succession fell to his brother Joseph Antony, who died in the same year. The elder of his two sons, Prince Paul Antony, born in 1711, rose in 1747 to the rank of field marshal lieutenant, was appointed ambassador to Naples in 1750, and died as field marshal in 1762. His brother Nicholas Joseph, born in 1714, attained the rank of field marshal, and had conferred upon him the title of prince, hereditary in both male and female issue. His son, Prince Paul Antony, born in 1738, became lieutenant field marshal, and died in 1794. He was the father of the princes Antony and Nicholas. The latter, born in 1765, served in the army, and subsequently in the diplomatic corps, and gained distinction as a promoter of arts and sciences, and as the founder of a gallery of paintings and engravings. It is said that in 1809 he refused the crown of Hungary offered to him by Napoleon. He died at Como in 1833. His son, Paul Antony, born March 10, 1786, distinguished himself as a diplomatist, chiefly at the court of England; but returning to his native country in 1842, he embraced the national cause, and in 1848, as Hungarian minister of foreign affairs, vainly attempted to bring about a reconciliation between the Austrian court and Hungary, resigning before the dissolution of the Batthyány ministry. By extraordinary munificence and extravagant displays of wealth, both abroad and at home, he ultimately brought about a legal sequestration of his immense estates. He died May 21, 1866, and was succeeded by his son Nicholas Paul, born June 25, 1817, who married in 1842 Lady Sarah, daughter of George Child Villiers, earl of Jersey. His entailed inheritance in Hungary embraces 29 estates with 21 castles, 60 towns, 414 villages, and 207 other landed possessions; the princely seat is at Eisenstadt. Besides these he is the owner of the domains of Pottenstein and Schwarzbach in Lower Austria, and of Edelstetten in Bavaria.

ESTHER, a Persian queen of Jewish descent, wife of Ahasuerus, and also the title of the Biblical book that contains her history, and the narrative of the delivery of the Jews by her from a general massacre throughout the Persian empire. Her original Hebrew name was Hadassah. The book is one of the smallest historical works of the Hebrew Scriptures, and one of the five so-called *Megilloth*, and belongs to the Hagiographa. It is written in correct but somewhat modern Hebrew, and distinguished by some new words, and the total absence of any refer-

ence to God, notwithstanding the providential character of the events related. This has led to the conclusion of some critics, that the book is a translation of or extract from a Persian chronicle, though its authorship has also been attributed to Ezra, Mordecai, and other distinguished Jews. The book narrates how the king, incited by his minister Haman, who was incensed by the independent spirit of the Jew Mordecai, resolved upon the massacre of all the Jews in his dominions, but was turned from his purpose by Esther, who, inspired by Mordecai, saved her nation at the risk of her own life. To commemorate the salvation of their people and the destruction of their enemies, Mordecai and Esther introduced the fast of the 13th of Adar, the day of danger, and the festival of Purim or lots, still celebrated by the Jews on the 14th and 15th of the same month, as days of entertainment and joy, and for sending presents to each other and alms to the poor. On the former of these days the *Megillah* is read in the synagogues. The Persian name of the queen has been differently translated; and that of Ahasuerus is a source of contradictory hypotheses among critics. From the last king of Media down to the last king of Persia, each monarch of that united empire has had his advocate. The claims of Xerxes are best supported by his character; those of Artaxerxes Longimanus, by the authority of the Septuagint and Josephus. The apocryphal additions to the book caused it to be violently attacked by Luther. Among the recent works relating to the book of Esther are: Baumgarten, *De Fide Estheræ* (Halle, 1839); Davidson, "Lectures on Esther" (Edinburgh, 1859); and Oppert, *Commentaire . . . d'après la lecture des inscriptions perses* (Paris, 1864).—By a singular coincidence, another Jewess Esther also attracted the love of a gentile king, Casimir the Great of Poland (1333-'70), became his mistress, and was able to protect her people in a time of persecution. She is the heroine of historical novels by Bernatowicz, Bulgarin, Bronikowski, Jósika, and others; and her memory is preserved by the tomb at Lobzów, near Cracow, once her residence.

ESTHONIA (Ger. *Esthland*; Esth. *Wiroma*), a government of European Russia, bounded N. by the gulf of Finland, E. by the government of St. Petersburg, S. by Livonia, and W. by the Baltic, in which lie Dagö and some smaller islands belonging to it; area, 7,611 sq. m.; pop. in 1867, 322,668. The inhabitants of the towns and the nobility are chiefly Germans, and the German language is predominant in the administration and in the schools and churches; but the rural population, who constitute a great majority of the people, are Esthonians. The surface is generally low, sandy, rocky, or marshy, and is interspersed with more than 200 lakes, but produces abundantly grains, flax, and pulse. There are many extensive forests of firs and birches. The climate is moist, cold, and salubrious; the winter continues for eight

months, and the transition to summer is sudden. The fisheries are productive; agriculture receives great attention, and the rearing of cattle, and particularly of sheep of the merino and Saxon breeds, is an important interest. Lutheranism is the prevalent religion, but there are also many adherents of the Greek church. The government of Esthonia is divided into the districts of Revel, Hapsal, Weissenstein, and Wesenberg. Capital Revel. Its governor is under the orders of a governor general who resides at Riga, and who has authority also over Livonia and Courland.—The Esthonians, who are also numerous in Livonia and other neighboring governments, are of Finnish descent, of slight stature, daring and vindictive. They embraced Christianity about the beginning of the 13th century, and fell successively under the power of the merchants of Bremen, the Danes, the Teutonic knights, the knights

Esthonian Women.

sword-bearers or Livonian knights, and the bishops of Riga and Semgallia. Threatened in 1555 with conquest by Russia, they preferred to recognize the authority of Eric XIV., king of Sweden, whose successors gave legal sanction to the rights of the Esthonians by various treaties, especially by that of Oliva in 1660. In 1710 the country was conquered by Peter the Great, and was definitely confirmed to Russia by the treaty of Nystadt in 1721. It received the title of grand duchy. There are Esthonian popular songs, naive and melancholy, versified in the Finnish manner, that is, metrically and alliteratively. The oldest of these is a song of the peasants of the canton of Revel, which has been sung from the time of the introduction of Christianity.

ESTIENNE, or *Étienne*, a celebrated French family of printers. See STEPHENS.

ESTILL, an E. county of Kentucky, intersected by the Kentucky river; area, about 300 sq. m.; pop. in 1870, 9,198, of whom 599 were colored. It is well supplied with water power, and rich in coal and iron. The surface is uneven or mountainous, and there are many extensive forests. The soil is moderately but not uniformly fertile. The chief productions in 1870 were 7,910 bushels of wheat, 376,792 of Indian corn, 25,642 of oats, 14,095 of potatoes, and 157,580 lbs. of butter. There were 1,956 horses, 1,871 milch cows, 3,029 other cattle, 6,146 sheep, and 8,718 swine; 7 distilleries, 2 saw mills, and 3 manufactories of pig iron. Capital, Irvine.

ESTOPPEL, an impediment or bar in law to a right of action or defence, arising from a man's own act or conduct. Estoppels are: 1, by record, which arise where judgment has been rendered by a court of competent jurisdiction, whereby the parties thereto and their privies are for ever precluded from alleging matters which would be contradictory to the record; 2, by deed, which being supposed an instrument of very solemn and deliberative nature, the party executing the same and his privies in law or in estate are not permitted to deny the facts which it evidences; 3, by matter *in pais*, as where a man stands by and sees his own property sold by a third person as the property of the seller, and fails to assert his title at the time, and another buys and pays for the property in good faith, he will be estopped or precluded from alleging his title afterward. In general it may be said that where one by his silence, when good faith required him to speak, has induced another to suppose that a certain state of facts exists, he shall not be allowed afterward to dispute such facts to the prejudice of the party thus deceived by his silence. (See EVIDENCE.)

ESTOVERS, a Norman term, equivalent to necessities. The most ordinary use of it was in reference to the right of a tenant of lands to take wood necessary for domestic or farming purposes. In such case it was an exclusive right, and related to wood upon the leased premises. Estovers are also called *botes*, and are classified in the old books as hay or hedge bote (wood for repair of fences), plough bote (wood for ploughs and other farm implements), and house bote (wood for fuel and repair of buildings). There could be also common of estovers, that is to say, a right of taking wood from other lands, either in common with other persons, or as an exclusive privilege appendant to a particular tenement. The alimony of a wife who had obtained a divorce *a mensa et thoro* was formerly called estovers, and could be recovered by a writ *de estoveris habendis*.

ESTRAYS, or Strays, domestic animals, usually designated as cattle, which are found wandering in enclosed lands, and whose owner is unknown. In England they belong to the proprietor of the manor on which they are found, provided that after proclamation in the

church and two market towns the owner does not appear to claim them within a year and a day. In the old books estrays were described as *pecus vagans, quod nullus petit, sequitur, vel advocat*; therefore dogs and cats were not included; a swan might be, but no other fowl. In the United States the regulation of estrays is by statute, and cattle at large in the public streets contrary to local regulations are included. They are allowed to be detained, and after a certain time and on proper notice, if not reclaimed, they are sold by public auction for the costs of keeping and sale.

ESTREAT (Lat. *extractum*; mediæval Fr. *estrete*), a term still in use in criminal proceedings, by which is signified the extracting or taking out a record of a court for prosecution in another court, or it may be in the same court. To estreat a recognizance is to indorse it by order of the court for prosecution. The use of the term probably grew out of the custom in England of sending all recognizances to the court of exchequer to be prosecuted.

ESTREES, Gabrielle d', mistress of Henry IV. of France, born in 1571, died April 10, 1599. Her father and mother were of noble birth. Gabrielle, who possessed remarkable beauty, was but 16 years old when her mother introduced her to the notice of Henry III.; but she retained his favor only a short time. She soon became well known for the number and rank of her lovers, among whom were the cardinal de Guise and the dukes de Bellegarde and Longneville. In 1590 she met Henry IV. for the first time at the château of Cœuvres, where she resided with her family. She inspired the monarch with a violent passion, which, however, did not interrupt her relation with her old lover, the duke de Bellegarde. The king caused her to take M. de Liancourt for her nominal husband, but subsequently divorced her, and raised her to the rank of marchioness of Monceaux, and in 1595 to that of duchess of Beaufort. He lavished riches upon her in great profusion, and at the time of her death she was the owner of more than a dozen estates, some of which are still pointed out in the vicinity of Paris. Her extravagance was unbounded. Henry would have divorced himself (as he afterward did) from Margaret of Valois, his legitimate wife, for the purpose of raising Gabrielle to the throne of France, if it had not been for his minister and friend Sully, who was the only person with whose influence she was unable to cope. Even this Henry appeared inclined to override, when the sudden death of Gabrielle, which many believed to have been caused by poison, ended the matter. She had three children by the king.

ESTRELLA, Serra da. See PORTUGAL.

ESTREMADURA. I. A province of Portugal, on the W. side of the kingdom, between Beira, Alentejo, and the Atlantic ocean; area, 6,872 sq. m.; pop. in 1868, 837,451. It contains the cities of Lisbon and Leiria. It is mountainous, being traversed by the Serra da

Estrella and its S. W. continuations. Its soil is watered by numerous streams, the principal of which are the Tagus and the Sadão. Grains, fruits, and wines are produced. It has suffered from earthquakes, and has unexplored mines. **II.** An old province of Spain, in the W. part of the peninsula, comprising the modern provinces of Badajoz and Cáceres, bounded N. by Salamanca, N. E. by Ávila, E. by Toledo, Ciudad Real, and Cordova, S. by Seville and Huelva, and W. by Portugal; area, 16,693 sq. m.; pop. in 1867, 733,749. It is entirely surrounded by mountains, and is divided into three parts by the rivers Tagus and Guadiana, and into two parts by the mountains of Guadalupe, San Pedro, and San Mamed. These mountains, forming but a single chain, traverse the province from E. to W., and nearly form the boundary between its two present divisions. The soil of Estremadura is very fertile, and if well cultivated would produce sufficient to support a third of the population of Spain; but nearly all the large proprietors reserve their lands for pasturage. A little barley and wheat are cultivated, and chestnuts are abundant, forming the principal food of the inhabitants: This province is distant from the sea, and has no great highways. Even its rivers are little used for navigation. Its manufactures are of no importance, and its mines of lead, silver, and coal are neglected. It was formerly a part of the kingdom of Leon, and was the last province conquered by Alfonso IX. of that kingdom; whence the name of Estremadura, from Lat. *extrema ora*, last region.

ESTREMOZ, a town of Portugal, in the province of Alentejo, 22 m. W. of Elvas; pop. about 6,600. The fortifications, once strong, are fast decaying. Pottery and leather are manufactured, and in the vicinity are marble quarries.

ESZÉK, or **Esseg** (Slav. *Osjek*), a town and fortress of the Austro-Hungarian empire, capital of Slavonia, in the county of Verőce, on the Drave, 13 m. from its confluence with the Danube, and 135 m. S. by W. of Pesth; pop. in 1869, 17,247. Fairs for cattle, corn, and other produce are held here four times a year. Of late the population and industry of the town have rapidly increased, the Drave having been made available for steamboat navigation. The fortress contains an arsenal and barracks for 30,000 men; during the revolutionary period of 1848-'9, it was occupied by the Hungarians until Feb. 14, 1849, when it surrendered to the Austrian Gen. Trebersberg. Not far from Eszék stand the famous bridges constructed by Solyman II. in 1566, to facilitate the entrance of the Turkish armies into Hungary. The town was a colony of the Romans, who called it Mursa; and it afterward became the residence of the Roman governors of Lower Pannonia.

ÉTAMPES (under the Franks, *Stampæ*), a town of France, in the department of Seine-et-Oise, 28 m. S. by W. of Paris; pop. in 1866, 8,228. It is on two small tributaries of the Juine, or Étampes, in a fertile valley, and is surrounded

with shady promenades. It has a ruined tower called Guinette, the only remnant of the ancient castle built by King Robert in the 11th century. There are several fine churches, a town hall, and a castle which is said to have been given in apanage to the duchess d'Étampes and other royal favorites. There is also a statue to Geoffroy-Saint-Hilaire, the naturalist, who was born here. The chief manufactures are soap, leather, counterpanes, woollen yarn, and hosiery. A considerable trade is carried on in wool, corn, honey, and flour, and there are more than 40 mills.

ÉTAMPES, **Anne de Pisseleu**, duchess d', a mistress of Francis I. of France, born about 1508, died about 1576. Her father, Guillaume de Pisseleu, was a country gentleman of Picardy. Anne was a maid of honor of the queen regent, when in 1526 she attracted the attention of her son Francis I. She became his favorite mistress, displacing the countess de Chateaubriant; he gave her for a nominal husband Jean de Brosse, afterward duke d'Étampes. The new duchess secured lucrative appointments for her relatives and friends, and wielded a paramount influence in the affairs of the nation. Upon the fine arts and in some other directions her influence was good, but the jealousy which sprung up between her and Diana of Poitiers, the mistress of the dauphin Henry, eventually became a source of calamity for her lover and for France. It was chiefly under the influence of this feeling that she betrayed to Charles V. the movements of the French army; and the disadvantageous treaty of Crespy in 1544 was due to the intrigues of Anne and of Diana. Anne was present in 1538 at the interview between Francis I. and Charles V., and according to the chroniclers of the times the emperor was fascinated by her beauty. The death of Francis (1547) proved fatal to her power. Henry II. banished her from the court, and she ended her days on one of her estates. It is said that she devoted herself to religion, and became a Protestant.

ETAWAH, a town of British India, the capital of a district of the same name, on high ground about 1 m. from the left bank of the Jumna, 80 m. W. by N. of Cawnpore, and 60 m. S. E. of Agra; pop. about 25,000. Ghauts, or flights of steps, some in ruins, others new and frequented by Hindoo devotees for religious ablutions, lead toward the river, across which is a ferry and at times a bridge of boats. A fort and a large jail are the principal buildings. The town was prosperous and important under the Mogul empire, but is now little more than a mass of ruins, and is generally described as one of the least attractive stations in India. It has some commercial consequence from its position at the junction of the roads from Calpee and Cawnpore to Agra, and contains a few bungalows and other military buildings.

ETECHEMINS, a tribe of Indians occupying the eastern part of the state of Maine, now represented by the Penobscots and Passamaquoddies. They lived chiefly in early times on

the St. Croix, and were between the Abenakis proper and the Micmacs, though in later times they were generally treated as part of the Abenaki nation. They now number about 1,000, half of them Penobscots on islands in the river of that name, and the remainder Passamaquoddies on the western shore of the bay of that name and on the Schoodic lakes. They are Roman Catholics, and have churches and schools, and a fund arising from land sold to the state; but they are declining from intestine divisions, and from the intermarriage of near kindred, the laws of Maine not permitting an Indian to marry a white.

ETEOCLES and POLYNICES, mythical kings of Grecian Thebes, sons of Œdipus and Jocaste. After the flight of their father, the brothers agreed to govern the kingdom alternately; but Eteocles refusing on the expiration of his term to surrender the sceptre, Polynices retired to the court of Adrastus, king of Argos, who gave him one of his daughters in marriage, and undertook to sustain him in the enforcement of his rights. They organized that confederacy of Peloponnesian chiefs whom Æschylus has immortalized, and whose expedition, undertaken to restore Polynices, is known as that of "the seven against Thebes." In the sieges which followed the success of the belligerents was various, and many warriors were slain, when the brothers, to prevent further effusion of blood, resolved to decide the contest by single combat, in which both perished. (See ANTIGONE.)

ETESIAN WINDS (Gr. *ετησιαί*, from *ετος*, year), the name given by the ancients to the N.E. trade winds which blow for about six weeks during the summer throughout the countries adjacent to the Mediterranean, especially its eastern portion. On the sea they are called by the fishermen *meltem*, probably from *mal temps*, in reference to the fury with which they blow, and the dangerous weather which they create for their small craft. On land they are equally salutary to men, beasts, and birds, and likewise beneficial to vegetation, by moderating the violent heat of the weather during the season of the dog days. In the Levant they commence toward the middle of July about 9 in the morning, continuing only in the daytime. The sun at that season is powerfully heating the surface under the tropic of Cancer, and rarefying the atmosphere south of the Mediterranean. Currents of air are thus drawn in over the desert of Sahara; but though in their passage across the Mediterranean they must become charged with moisture, the clouds are dispersed as they pass the margin of the hot sands, and the vapor dissipated in the rarefied air is swept on, to be again collected together and precipitated in a cooler region.

ETEX, Antoine, a French sculptor, painter, and architect, born in Paris, March 20, 1808. He studied under Ingres, and after the production in 1829 of his "Hyalanth killed by Apollo," he spent some time in Italy and visited other

countries at the expense of government. Returning to Paris, he exhibited in 1833 a colossal group of "Cain," which procured him orders from the government, and he has since produced many statues and architectural designs. He also excels as a painter and draughtsman. In 1864 he exhibited paintings entitled "The Ancient Slave" and "The Modern Slave." He has published *Essai sur le beau* (Paris, 1851), and *Cours élémentaire de dessin* (3d ed., 1859).

ETHELBALD, king of Wessex, son of Ethelwulf, king of the Anglo-Saxons, obtained the throne of Wessex, about 856, and died in 860. While Ethelwulf was making a journey to Rome, on his way back from which he married Judith, the young daughter of the French monarch, Ethelbald formed the project of seizing the throne. A civil war was prevented only by the moderation of Ethelwulf, who resigned to his son the dominion of Wessex, and confirmed that portion of the kingdom to him in his will. The reign of Ethelbald was peaceful, but he excited general disapprobation by marrying, contrary to the canonical law, his step-mother Judith. Ecclesiastical and popular displeasure forced him to a separation, and Judith returning to France eloped from a convent with Baldwin, called *Bras de Fer*, afterward count of Flanders. From this union descended Matilda, wife of William the Conqueror, and through her the race of English sovereigns.

ETHELBERT, king of Kent, born about 545, ascended the throne in 560, and died in 616. As the representative of Hengist, he claimed superiority among the Saxon states, but was twice defeated in the early part of his reign by Ceawlin, king of Wessex. About 589 he had acquired the dignity of bretwalda, or leading chief of the Anglo-Saxons, Ceawlin being deposed by his subjects, and dying a few years later. The most remarkable event of his reign was the introduction of the Christian religion into Britain. His queen Bertha, a daughter of Charibert, king of Paris, professed this faith, and through her it had already become somewhat known to the king and to a portion of the people, when in 596 a company of Italian and French monks, sent by Pope Gregory the Great, under the conduct of Augustin, landed on the isle of Thanet. They were received by the king beneath an oak, the sacred tree of the druids, where it was supposed any magical spell would be without influence; and after a conference he gave them permission to preach without molestation, though he himself had then no intention of abandoning the gods of his fathers. The queen prepared a residence for the new apostles, and in 597 Ethelbert received the sacrament of baptism, and his example was followed by 10,000 of his subjects. About 600 he issued the earliest remaining code of Anglo-Saxon laws, consisting of 89 enactments, relating principally to the amount of pecuniary fines payable for various transgressions.

ETHELBERT, third king of the Anglo-Saxons, son of Ethelwulf, died in 865 or 866. He in-

herited in 857 all the kingdom excepting Wessex, and on the death of his brother Ethelbald in 860 possessed himself also of that portion. During his reign the Northmen sacked the city of Winchester, landed on the isle of Thanet, pillaged a part of Kent, and appeared in Northumbria under Ragnar Lodbrog.

ETHELRED (also written **EDLRED** and **ETHE-RED**) **I.**, fourth king of the Anglo-Saxons, son of Ethelwulf, and successor of his brother Ethelbert, ascended the throne in 866, and died in 871. His reign was a continuous struggle against the Northmen. The sons of the Danish chieftain Ragnar, whom the Northumbrians had put to death, appeared in East Anglia, took possession of the city of York, and defeated and slew two Northumbrian princes who attempted to recover it. Marching southward they took up their winter quarters at Nottingham, whence they retired without a battle after being for some time beleaguered by Ethelred and his brother Alfred. Passing into East Anglia, they burned on their way the monasteries of Bardney, Croyland, and Medeshamstede, ravaged the nunnery of Ely, and seized and murdered the East Anglian king Edmund, who was hence revered as a martyr. They were met in 871 by Ethelred and Alfred at Reading, but were able to maintain their ground. Being attacked by Alfred four days later at *Æscesdun*, they were routed and were pursued for a night and a day. Within a fortnight another battle was fought at Basing, in which the invaders were victorious, and an obstinate engagement soon followed at Merton. Ethelred died of a wound, and left the kingdom to Alfred.

ETHELRED II., surnamed the Unready, king of the Anglo-Saxons, son of Edgar and successor of Edward the Martyr, born in 968, ascended the throne April 14, 978, and died in London, April 23, 1016. His reign was long, and the most unfortunate in Anglo-Saxon history. The son of that Elfrida whose criminal ambition had caused the tragic death of the late king, he never possessed the affections of his subjects, and was acknowledged only because there was no other prince of the royal blood. The Danes made several invasions, appeared with a formidable armament in 991 off the coast of Essex, took Ipswich, and advanced into the country. They were met at Maldon by Brithnoth, ealdorman of that country, who, after having foiled their efforts for 14 days, was defeated and slain. The king, listening to the advice of Siric, archbishop of Canterbury, and many of the nobility, purchased the departure of the enemy by paying them 10,000 pounds of silver, collected by an oppressive tax on landed property, which from this time was permanently established under the name of *Danegelt*. A fleet fitted out against them was rendered useless by the treachery of Alfric, its commander, who afterward deserted to the enemy. In 993 the Danes, joined by three chieftains who were sent to oppose them, captured the castle of Bambor-

ough and ravaged both sides of the Humber. In 994 the Northmen, under the command of Sweyn, king of Denmark, and Olaf, king of Norway, attacked the centre of the kingdom, sailed up the Thames, and laid siege to London, from which being repulsed, they plundered Essex, Sussex, and Hampshire, and having obtained horses were spreading devastation far into the inland counties. The forbearance of the invaders was now purchased by the payment of 16,000 pounds, and in 1001 of 24,000 pounds of silver. Ethelred and his advisers then determined to rid themselves of the Danes by a general massacre. Secret orders were sent to every town and county, and on Nov. 13, 1002, the festival of St. Brice, multitudes of every age and sex were butchered. Next year Sweyn reappeared on the south coast, and from this time left the kingdom no rest, devastating the country from Exeter to the heart of Wiltshire, burning cities and villages. He consented to a peace in 1007 on payment of 36,000 pounds. Soon the war began again, and was again momentarily ended in 1012 by the payment of 48,000 pounds. In 1013 Sweyn openly declared his purpose of conquering England, landed at Gainsborough, and marched triumphantly to the walls of London. Repulsed from the capital, he marched to Bath, where he was proclaimed king of England, and recognized by the thanes of Wessex, Mercia, and Northumbria. Ethelred fled in haste to Normandy, and found an asylum with his brother-in-law Richard, the Norman duke. The death of Sweyn two or three weeks later recalled the fugitive monarch, who, restored to power by the renewed allegiance of those tributary rulers who had deserted him, is said to have inflicted new cruelties upon the Danish population. Canute, the Danish successor, was roused by these atrocities to renewed efforts to subdue England. In 1015 he once more reduced a great part of it to submission, and had advanced on London when Ethelred died, just as preparations were making to attack the city.

ETHELWULF, second king of the Anglo-Saxons, son and successor of Egbert, ascended the throne about 836, and died in 857 or 858. He began his reign by transferring the provinces of Kent, Essex, and Sussex to the government of his eldest son Athelstan. For many years he waged incessant contests with the Danes, who annually made inroads into England, and though repulsed and defeated always carried off booty. In 850-'51 a part of them dared for the first time to pass the winter in England. Strongly reinforced in the spring, they sailed up the Thames, sacked Canterbury and London, and met Ethelwulf at the head of the West Saxons at Okely. After an obstinate battle the Danes were defeated with a loss greater, it is said, than they had ever before suffered, and other divisions of their forces were defeated by Ceorle in Devonshire, and by Athelstan at sea. Yet they maintained their settlement on the isle of Thanet, but were cautious during the re-

mainder of Ethelwulf's reign. In 853 the king marched against the Welsh, and reduced them to subjection. Shortly afterward he made a visit to Rome, accompanied by his son Alfred, who there received the regal unction and the sacrament of confirmation. He returned through France, where he tarried to marry Judith, daughter of the French king. His son Athelstan meantime had died, and Ethelbald was usurping the kingdom, when he returned and yielded to the latter the government of Wessex. He survived this partition only two years, which he passed in charity and devotion.

ETHER, or **Æther** (Gr. *αἰθήρ*, the upper air, from *αἰθεω*, to burn), in physics, a hypothetical fluid of great tenuity, which by ancient as well as by modern philosophers has been supposed to occupy all space; hence called the cosmic or luminiferous ether. Among the ancient Greeks it was the personified idea of cosmic material as well as force. According to Hesiod, Æther was the son of Erebus and Night and brother of Day. The children of Æther and Day were the heavens, the land, and the sea, from which we are naturally led to conclude that it was considered one of the elementary substances out of which the universe was formed. In the Orphic hymns Æther is represented as the soul of the world, from which all life emanates. Anaxagoras called ether the principle of fire, and Plato described it as a matter purer and lighter than air, which being diffused throughout space, it would be impossible to ascertain if it had weight. The modern ideas of the interstellar ether differ in many respects from those of the ancients, and have assumed a more precise and scientific form; but the speculations of the old philosophers seem to be a foreshadowing of modern theories. Descartes, in his treatise on dioptrics, entertains the idea of an ether, or a "subtile medium" for the transmission of light, which he believed to be "a certain motion or most rapid and lively action coming toward the eye." Huygens was the first to give system and mathematical order to the theory. He conceived that from every point of a luminous body undulations are propagated through an ethereal fluid diffused throughout space, which possesses the property of extreme tenuity and infinite elasticity, and by the most refined mathematical demonstrations accounted for so many of the phenomena of light as to lay the broadest foundations for the subsequent labors of his followers. Newton did not accept the undulatory theory of light, although in the 22d query of his third book of optics he does propound the question as to whether vision may not be caused by a propagation through the fibres of the optic nerve of vibrations communicated by an ethereal medium, thereby stating his belief in the existence of such a medium, as he also does when treating of the subject of heat. His theory that light is caused by the emission of luminous corpuscles from all incandescent bodies was so generally accepted for more than 100

years, that the doctrine of a luminiferous ether, which seems to have been generally considered as peculiarly a fundamental part of the theory of Huygens, did not occupy much attention until the investigations of Young, Fresnel, Euler, and Cauchy placed the undulatory theory of light in the position of a demonstrated fact. The luminiferous ether is now supposed not only to occupy all space between the heavenly bodies, but to permeate all ponderable matter, and to move in undulations between its particles, which undulations may be modified by the nature of the matter, and transformed into heat or other force. It is supposed to be uninfluenced by gravitation, to preserve a uniform density when not contained within the interstices of ponderable bodies, and has also been supposed to offer no resistance to their passage; but the diminution in the periodical revolution of some of the comets, as Encke's, has been ascribed to a retardation possibly due to the resistance of interstellar ether. From being at first considered as a medium for the transmission of light, it has within the last half century, upon the undulatory theory, been adopted as that of heat also, since it has been demonstrated that both heat and light are the effects of undulations of different amplitudes; and at the present time the question is raised as to whether it may not also be the medium, or at least an important agent, in the manifestation of electricity, since this force is now regarded as a correlation of light and heat. It must be observed that Euler maintained only the doctrine of undulations, and rejected that of an ethereal medium, as do several physicists of to-day, among whom is Prof. Grove, contending that the undulations are produced in the ponderable matter, whatever it may be, which constitutes the medium of transmission. The arguments of these philosophers are stated by Prof. Grove in his work on the "Correlation of Physical Forces." Among them may be briefly noted the following: It has been impossible hitherto to produce a perfect vacuum; in other words, to create a space which shall be void of ponderable matter. The tendency of the particles of bodies to fly from their surfaces, even under ordinary circumstances, is so great that the odor of many metals, as iron, copper, tin, and zinc, is always plainly perceptible. Water in a vessel within the exhausted receiver of an air pump will acquire a taste of the tallow used between the edge of the receiver and the pump plate. The tendency of gaseous matter to fly off into space is so great that it is contended that no interstellar vacuum could continue for an unlimited time. Another argument is that light is lost in the interstellar spaces; for if not, all the stars being suns, there ought to be no night. To account for this loss, the light must be supposed to be transmuted into another force, and this requires the intervention of matter, which is believed to be furnished by the mingling of

portions of the atmospheres of worlds in the interstellar spaces; and the retardation of comets has been ascribed to this matter. This argument is not affected by the law that light decreases in proportion to the square of the distance, because, although the rays diverge in all directions from every source, the field of the heavens, as Prof. Grove remarks, is everywhere studded with suns, so that the sum of the rays which would reach the earth, if they retained their luminous property, would furnish more light than is actually received. Again, when as near an approach to a vacuum as is possible has been formed, it has been found to offer an effectual barrier to the passage of the electric spark; and regarding electricity as a correlation of light and heat, it is asked why it will not employ the ethereal medium which upon that hypothesis must pervade the vacuum. This objection loses weight from the fact that the space which contains no medium for the transmission of electricity, nevertheless offers one for the transmission of light and heat. The difficulty of accounting for the polarization of light by assuming that the undulations take place in the molecules of the polarizing body, is greatly diminished by adopting the doctrine of a special medium, as the luminiferous ether. A further consideration of the subject will be found in the articles **LIGHT** and **HEAT**. (See also **ELASTICITY**.)

ETHER, in chemistry, the name given to a class of highly volatile, inflammable, spirituous liquids, possessing a sweetish taste and peculiar fragrance, obtained commonly by distilling alcohol in mixture with some acid. Their composition is somewhat variable according to the acid employed in their preparation, and this gives them their distinctive names, as sulphuric ether, nitric ether, &c. Yet these acids do not in all cases furnish any of the ingredients of the ether, and the same ether may sometimes be produced by the action of other substances upon alcohol, as well as of the acid usually employed. This is especially the case with sulphuric ether, and as it contains no sulphuric acid, and is by far the most common form of ether, it is now admitted into the United States and London pharmacopœias by the name of æther, as it was before known in common use. This ether, it is supposed, was known to Raymond Lully, who lived in the 13th century. Valerius Cordus in 1540 described the method of making it. Frobenius in 1730 first brought it prominently forward in a paper published in the "Philosophical Transactions;" and by a note appended to this, it appears that Boyle and Newton had both directed their attention to it.—The preparation of ether was formerly conducted by distilling in a glass retort a mixture of equal parts of sulphuric acid and alcohol at a moderate heat, and, when about one third of the whole had come over, adding half as much alcohol as before, and again distilling. But a better method is to conduct the process on a larger

scale with the use of a leaden still heated by high steam passed through in a spiral pipe; and the alcohol is best introduced in small quantities at a time by a pipe which passes through the upper part of the still. Such is the apparatus used at the apothecaries' hall, London. The heating by steam obviates the danger of explosion, to which the process is liable when the vapors that escape come in contact with a flame. The apparatus given by Brande is convenient either on a large or small scale. In a glass flask are introduced 8 parts by weight of concentrated sulphuric acid and 5 parts of spirit of wine of specific gravity 0.834. This is set in a small sand bath, which may be conveniently heated by a gas light. A thermometer graduated at least to 320° F. passes through the cork, the bulb being in the liquid. There is also a tube reaching to the bottom, and expanding at top into a funnel. This is intended to receive more alcohol slowly dropped into it as the process goes on. A glass tube of large bore conveys the vapor through the condenser, which is surrounded with cold water, and the liquid drops from the end of the tube into a proper receiver. By keeping the temperature as nearly as possible to 300°, the ebullition goes on rapidly, and the quantity of liquid in the flask may be kept nearly the same for several hours, the alcohol as fast as it is admitted being converted into the vapor of ether and of water. These condense together, but in the receiving vessel they separate, the water sinking to the bottom together with $\frac{1}{10}$ of its volume of ether dissolved in it. If a weak acid be used or too much alcohol, so that the boiling point of the mixture is reduced below 260°, the alcohol is apt to pass over unchanged. It is important to keep up a rapid, or even violent boiling, at a temperature between 260° and 310°. At about 320° olefant gas and other undesirable products are generated. By the continuous process of Dr. Brande, a small quantity of sulphuric acid may be made to convert into ether a large quantity of alcohol. It might serve for an indefinite time but for its slow volatilization and the passing over of its vapor with the others. Ether is purified by shaking it in a close vessel with twice its bulk of water. After standing, the ether is poured off, and the water that may be still present is taken up by mixing quicklime with it. Then by distilling, pure ether is obtained.—Ether is remarkable for its great volatility. Its vapor escapes in pouring the fluid from one vessel into another, so that if a lighted candle is near there is danger of the whole being suddenly inflamed. A mixture of 10 volumes of oxygen and one of ether vapor explodes violently by an electric spark. The vapor is so much more dense than air, being as 2.58 to 1, that it can be poured out of one vessel into another, displacing the air in this, and showing its presence by taking fire on the application of a match. Its rapid evaporation produces in-

tense cold; a few drops being made to cover a drop of water and then blown upon through a tube, the water is frozen directly. Ether itself, however, does not freeze, even at 166° below zero. Its boiling point varies with the nature of the vessel containing it; at the ordinary pressure it boils at 96.5° . Its specific gravity at 68° is 0.713. It has neither an acid nor alkaline reaction; but after being exposed to the air and light, a little acetic acid is formed in it. Ether unites with alcohol in all proportions. It takes up $\frac{1}{10}$ of its volume of water, and water does the same of ether. If water dissolve more than this, the ether may be suspected of being adulterated with water and alcohol. The ultimate constituents of sulphuric ether are carbon 4 equivalents, hydrogen 10, and oxygen 1, or $C_4H_{10}O$. The radical ethyle consists of C_2H_5 , and ether is regarded as its oxide, alcohol as its hydrated oxide.—Various preparations of ether are largely employed in medicine, surgery, and obstetrics. When administered by the stomach they are stimulant and antispasmodic. Some of them have been used in fevers and nervous affections, and in other diseases to relieve spasm, nausea, and vomiting. Ether has also been administered to remove intestinal worms, which it is supposed to stupefy and cause to relax their hold. By far the most important preparation of ether is the concentrated sulphuric ether, used by inhalation to produce anæsthesia and muscular relaxation. It is indicated whenever these objects are to be attained, as in the case of operations, surgical and obstetric, in hernia, stricture, dislocations, fractures, neuralgia, tetanus, dysmenorrhœa, colic, convulsions, feigned diseases, &c. The use of ether by inhalation to produce intoxication and to relieve pulmonary distress was known long before its anæsthetic properties were discovered. These were first practically demonstrated Oct. 16, 1846, when sulphuric ether was administered by Dr. Morton at the Massachusetts general hospital in Boston to a patient upon whom an operation was performed by Dr. J. C. Warren. (See ANÆSTHETICS.) The action of ether is very similar to that of chloroform. It is possible to produce death by asphyxia with an overwhelming amount and reckless use of ether, although even this is not easy; but it is difficult if not impossible to find a single instance of death which can fairly be attributed to the effects of the drug when used in a moderately careful manner. This is in marked contrast with the results obtained from the inhalation of chloroform, a fact at last acknowledged by many of those who have heretofore employed the latter. The deaths from chloroform, which experience shows to occur even with the most careful administration, and which appear to depend upon a rapidly developed paralysis of the respiratory centres in the medulla oblongata or upon sudden paralysis of the heart, do not happen with ether. The best and simplest method of administering

ether by inhalation is to pour it upon a sponge or towel, and then apply the latter over the mouth and nose. At first the sponge should be held a few inches from the mouth so as to allow a free mixture of atmospheric air; as soon as the patient gets over the primary sensation of choking or suffocation, fresh ether may be added and carried close to and over, but not on, the mouth and nose. Ether is so inflammable that a light should not be brought near to it. The inhalation may be kept up with safety for hours if necessary. Ether may be used externally to produce cooling by its rapid evaporation. If applied in the form of a spray, by means of an "atomizer," the skin may be frozen so that small surgical operations may be performed without pain. For this purpose, however, it has been nearly superseded by a light coal oil of low boiling point, called rhigolene.—Several of the ethers exist in fruits, giving them their peculiar flavors; and the alcoholic liquors distilled from these fruits retain these principles in combination with some acid. Thus cænanthic ether combined with cænanthic acid forms the oil which contains the fragrance of brandy and some other spirits.

ETHEREGE, or **Etheridge**, Sir George, an English comic author, born about 1636, died about 1690. He studied at the university of Cambridge, travelled on the continent, abandoned law for literature, and became known as one of the wits and libertines of the reign of Charles II. His comedies entitled "The Comical Revenge, or Love in a Tub," "She Would if She Could," and "The Man of Mode, or Sir Fopling Flutter," are marked by a sprightlier and wittier dialogue than had before been displayed in the English comic drama. The author was an associate of Buckingham, Rochester, and other gay courtiers and pleasure-seekers of the time, and he introduced upon the stage the manners and characters with which he was familiar. He also wrote a few coarse songs and lampoons. He lived licentiously, wasted his fortune, and died by falling down stairs after a debauch.

ETHERIDGE, John Wesley, an English clergyman, born at Youngwoods, Isle of Wight, Feb. 24, 1804, died May 24, 1866. After a careful education, chiefly under his father's direction, he entered upon the work of the Methodist ministry, and in 1827 was stationed at Hull. Through failing health he became a supernumerary in 1838. In 1843 he took up his residence in Paris, and pursued his oriental studies through the aid furnished by the great public libraries of that city, and under the special instruction of M. Quatremère and the abbé Bargès. In 1845 he became pastor of the mission Methodist church in Boulogne. On the recovery of his health in 1847 he returned to England, and occupied some of the most important stations of the British conference till his death. Among his numerous writings are: *Horæ Aramaicæ* (12mo, London, 1843); "The

Syrian Churches, their early History, Liturgies, and Literature" (1849); "The Apostolic Acts and Epistles, from the Peshito" (1849); "Jerusalem and Tiberias, a Survey of the Religious and Scholastic Learning of the Jews" (1856); and "The Targums of Onkelos and Jonathan ben Uzziel" (1862).

ETHIOPIA. See MORAL PHILOSOPHY.

ETHIOPIA (Gr. *Aiθiopia*, from *αἰθερ*, to burn, and *ὥψ*, countenance), an ancient country of Africa, south of Egypt. The name was also used by the Greeks as an ethnic designation of all dark-complexioned races in Africa and Asia. The tribes most frequently mentioned were the Blemmyes, Megabari, Ichthyophagi or fish-eaters, Macrobi or long-lived, and Troglodytae or cave-dwellers. As late as the time of Darius we find "Ethiopians of Asia" forming part of the 17th satrapy.—Ethiopia proper was bounded N. by Egypt, W. by the desert of Bahinda, E. by the river Astaboras, and S. by the districts above the modern city of Khartoom, at the junction of the Blue river and the White Nile. In a wider sense, ancient geographers designated as Ethiopia the whole region between the Red sea and the Atlantic ocean, S. of Libya and Egypt. Pliny divides it by the Nile into East and West Ethiopia. Ethiopia proper included the state of Meroë, which was probably centred in the modern Sennaar; and as the city of Meroë became the capital of the land during the Meroë dynasty, the whole of Ethiopia was sometimes spoken of as the kingdom of Meroë. Another Ethiopian capital was Napata, which was probably in the neighborhood of Mount Barkal; but there is reason for supposing that this word designated a movable royal residence rather than a fixed locality.—The early history of the country is obscure. About 3,000 years before our era a considerable branch of the Cushite race, who had probably dwelt in Hedjaz, Arabia, crossed the Red sea, and settled in Ethiopia, the land of Napata and Meroë, till then inhabited by negroes. These regions of the upper Nile were from that time designated as the land of Cush. (See CUSH.) Other Cushites, called Sabæans, established themselves further south on the coast of Africa, opposite Yemen. The northern Cushites soon mixed with the negroes and Egyptians, and acquired peculiarities in type and language which separated them from the kindred race on the coast. As early as the 12th Egyptian dynasty (about 3000-2850 B. C.) they seem to have grown dangerous to the Egyptians, as the fortresses of Kumneh and Semneh were built near the second cataract of the Nile to oppose them. Several steles recently found show that Osortasen III. conquered them, and in the tomb of Amen, one of his generals, is an account of the campaign and his subsequent administration of the new province. The Ethiopian history of the thousand years following has not yet come to light. During the 17th century B. C. (according to the chronology of Mariette), the

Ethiopians were again at war with the Egyptians. Amen-hotep I. (Amenophis) was not as successful as Thothmes I., his successor, who left a description of his exploits on the rocks on the banks of the Nile, opposite the island of Tombos, about lat. 19° 30' N. The Ethiopians remained quiet for about two centuries, but rebelled again at the beginning of the 15th century, and were subdued by Har-em-Hebi, who, according to an inscription at Silsilis, "chastised the land of Cush as he had promised his father." In the time of Rameses II. the Ethiopians revolted again, and with them the negro tribes of Libya that had been subject to Egypt; but after long and bloody wars they were again subdued. In the subsequent period the country was nearly every year invaded by the Egyptians, who came on a sort of slave-hunting expedition, and carried away thousands of every age and of both sexes. At the invasion of Egypt by the descendants of the shepherds, Merneptah (1341-1321 B. C.) sought with 300,000 men an asylum in Ethiopia, and remained there till his son Seti II., 20 years later, regained the throne. The Ethiopian king Azerkh-Amen (the Zerah of Scripture) invaded Egypt during the reign of Usarken I. (or of Usarken II.), and penetrated into Palestine, where he was finally conquered about 941 by Asa, king of Judah. His defeat was so complete that he seems not even to have maintained his position in Egypt, but to have retired at once to his kingdom. Two centuries later, however, the kings of Ethiopia gained the crown of Egypt. Shabaka, the Sabaco of the Greeks and the So of the Bible, conquered all Egypt to the Mediterranean, and burned alive the king Bokenranf. Shabaka was subsequently called on by Hoshea, king of Israel, for assistance against the Assyrians; but he started too late to save Samaria, though an inscription at Karnak names Syria as tributary to him. A little later Tahraka (Tirhakah) successfully fought the army of Sennacherib, but warded off the danger for a short time only, for Esarhaddon entered Egypt and conquered him near Memphis. Esarhaddon remained two years in the country, and entitled himself "king of Egypt and Ethiopia" (669). Tahraka reconquered the whole Nile valley, but was not able to maintain his supremacy against the troops of Asshur-bani-pal, and retreated beyond the cataracts. The insurrection that broke out soon after in the Delta gave Tahraka another opportunity to descend the Nile, and he drove out the Assyrians. Necho, the general of Asshur-bani-pal, regained the Delta, and Rot-Amen, son-in-law of Tahraka, succeeded only to the thrones of Thebes and Napata. He put to death Necho, whom he had taken captive in a battle for the possession of the Delta, but was finally driven back to his Ethiopian states by Asshur-bani-pal, who came in person to reconquer Lower Egypt. Rot-Amen died without direct heirs, and Amen-meri-Nut, who was probably only distantly related to him, was proclaimed king.

He entered Egypt with a large army, and claimed the sovereignty. He was gladly received at Thebes, but the chiefs of the Delta united against him, and a bloody battle was fought before he entered Memphis. Amen-meri-Nut does not seem to have cared greatly for the crown of Egypt, for, after receiving an immense tribute from the princes of the Delta, he withdrew to his country. The Ethiopian kings continued in possession of the Thebaid during the time of the dodecarchy in Lower Egypt. Amen-iritis, the queen whom Pankhi II., the successor of Amen-meri-Nut, had married to legitimate his occupancy of the Ethiopian throne, seems to have been a woman of superior merit, and, being charged with the regency of Egypt under three successive Ethiopian kings, rendered herself very popular in the Thebaid. Her daughter Shap-en-ap became the wife of Psammetik I. (Psammetichus, 664-610), who in alliance with the Greeks had dethroned the 11 kings his colleagues, and ruled over Lower Egypt. The favors which this king bestowed on foreigners offended the military class, and they emigrated in a body of 200,000 men to Ethiopia, where they formed a separate colony. The Ethiopians soon after had to resist an invasion by Psammetik II. (Psammis, 594-588), the successor of Necho II., who had married his own aunt, Net-aker, daughter of Shap-en-ap, in order to create a right to the Ethiopian sovereignty. After the conquest of Egypt by Cambyses in 525, the Ethiopians were also threatened with being absorbed in the great Persian empire. A numerous force, led by Cambyses, marched toward their frontier, but had to return; for leaving the banks of the Nile, and attempting to cross the Nubian desert, the army nearly perished with famine. The Ethiopians were left unmolested by Darius (521-486), who was satisfied with receiving from them a very small tribute. They sent to Persia every third year 4 pints of gold dust, 200 logs of ebony, 5 negro slaves, and 20 tusks of ivory. When Egypt was ruled by the Ptolemies, the arts and enterprise of the Greeks also entered Ethiopia, and led to the overthrow of the tyranny of the priests, and to the founding of Hellenic trading posts on the coast of the Red sea. Ptolemy Evergetes (247-222) conquered the southern country, and set up a throne of white marble with an inscription of his conquests. The Ethiopians soon regained their independence. During the reign of Augustus they advanced under their queen Candace as far as the Roman garrisons at Philæ, where Petronius, the legate of the prefect of Egypt, Ælius Gallus, repulsed them and pursued them to the neighborhood of Napata. But it appears that the Romans did not enter into possession of any part of Ethiopia, and that Augustus remitted the tribute. The influx of Arabs must have been very great, for at this period the population of Ethiopia is frequently spoken of as Arabian. For the history of the country

during our era, see *ABYSSINIA*.—The monuments of Ethiopia are in part of a decidedly Egyptian character. Many temples have been found wholly or partly hewn in the rocks of the mountains. Tombs are not frequent. Near Mount Barkal are the remains of several pyramids, which differ from the Egyptian in being much higher proportionally to the base. Higher up the river the monuments are wholly Ethiopian in style, and indicate the great wealth and culture of the ancient nation. Lepsius gives a detailed description of them. He found in all 30 names of kings and queens, and it appears that the kings were at the same time high priests of Ammon. The eldest son seems to have inherited the throne, unless the wife of the king should survive, in which case the succession fell to her. The crown prince during the lifetime of his father was a second high priest of Ammon. The worship of Ammon and Osiris was carried, according to Herodotus, from Meroë to Egypt, and the temple of Karnak and several Nubian monuments seem to commemorate this migration. The constant intercourse of the Ethiopians with the Egyptians renders it probable that the two nations had many points of agreement in manners and customs. (See *EGYPT*.)

ETHIOPIA, Languages and Literature of. The inscriptions on the pyramids in Ethiopia consist in part of hieroglyphs strongly resembling the Egyptian; but the language of the two countries was not the same. The Ethiopians used the hieroglyphs as a sort of sacred character, but without a complete knowledge of their use, and evidently rather as an ornament than as a means of conveying information. There is at least no doubt that at the time of the erection of the oldest pyramids a demotic graphic system was commonly in use among them. The prominent position which this style of writing occupies on the monuments, while the hieroglyphs seem to furnish at best only marginal notes, shows clearly that it must have been the current language of the country. It resembles the Egyptian demotic, but the constant repetition of the same signs leads to the supposition that it had a more limited alphabet, perhaps not exceeding 30 signs. The analogy of the history of the development of the Ethiopic and the Egyptian graphic systems extends still further. At a later period an Ethiopic-Greek style of writing came into use, which may be compared to the Coptic, and from which it borrowed several letters. (See *EGYPT, LANGUAGE AND LITERATURE OF*.) The Ethiopic-Greek is found in the inscriptions of Soba and in many others, especially on the walls of the temple in Wady es-Safra. These and the Ethiopic demotic inscriptions contain undoubtedly the true language of ancient Ethiopia; but its vocabulary and grammar have not yet been determined.—The language now designated as Ethiopic was spoken in the subsequent Abyssinian empire. It was originally one of the many dialects of the Arabic-African

branch of the Semitic stem. Tigré, with its capital Axum, was probably the first seat of it, and it spread thence with the formation of the Abyssinian empire over a larger territory, and became the chief language of the country. When the S. W. provinces gained the ascendancy and the seat of government was transferred to them, the Amharic dialect, which was in general use in that region, rose to the rank of a court language. The Ethiopic remained, however, for nearly three centuries more the literary and business language of the empire. The invasion of the Galla tribes and the subsequent division of the country, as well as the introduction of Mohammedanism, led gradually to its extinction. The Ethiopic church continued to study and use it as a sort of sacred language; but there are probably very few among the priests who are still conversant with it. The Amharic is now the most widely spoken dialect in the regions of ancient Ethiopia. It is used, though with variations, in Shoa and the district between the Tacazze and the Abai. The Tigré has preserved a greater resemblance to the Ethiopic, or the language of the former Abyssinian empire.—The name Ethiopic is derived from the classic appellation of this country, and passed over from the Greeks to the Abyssinians themselves. They called their country **አጥላጦ**, Aithiopya, and their language **ግዕዝ** Aithiopya. But the original native name of the people and their language is **ግዕዝ**, Geez, signifying emigration, and in a secondary sense emigrants, or the free. In origin and character the Ethiopic or Geez is a pure Semitic language. It was carried by emigrants from Yemen to Abyssinia, and with the exception of a few names of plants and animals, which it incorporated from the dialects current in the new country, and of a few commercial terms learned from Greek traders, it was kept free from foreign admixture. Its relation to Arabic is attested by the final short vowels in the construction of words, the large number of roots of three and four syllables, the internal formation of the plural, the construction of the subjunctive from the imperfect, and by many other characteristics not found in the North Semitic tongues. In other respects the difference is too great to warrant us in classifying the Ethiopic as a dialect of the Arabic. It is safe to infer that the Ethiopic developed for a time, after its separation from the North Semitic stem, somewhat in the direction of the Arabic, and then returned to the principles of the parent tongue. For this reason many old Semitic forms lost in Arabic are found again in Ethiopic. This strange mixture of the old and the new leads to the conclusion that the language passed through a history of at least 1,000 years before it attained to the type presented by the texts that have come down to us.—The Ethiopic system of writing differs in form and character from all known Semitic languages. It resembles the Himyaritic, and represents with it the southern branch

of graphic systems into which the prototype of the Semitic writing was early divided. It was originally written with consonants only, and from right to left; but the Abyssinians learned very early to write in the opposite direction, and to indicate vowel sounds by the addition of rings and strokes. The vowel signs came into use as early as the 5th century of our era; they are superior to the methods of indicating vowels employed by other Semitic tongues. Each of the 26 consonants that compose the Ethiopic alphabet has seven distinct forms. The simple consonant is uttered with the sound of *ā*, and its variants indicate the vowels *ā* (pronounced like *oo* in *boot*), *ī*, *ē* (sounded as in *father*), *ō*, and *ū*. The last named variant is often equivalent to the simple consonant without vowel sound. Four consonants, *q*, *kh* aspirate, *k*, and *g*, received occasionally from the Abyssinians a peculiar pronunciation not indicated by the ordinary forms, introducing the sound of *u* between these consonants and *a*, *e*, and *i*. These utterances were indicated by five special vowel signs. The later Ethiopic used also the sign of *ūd* with the value of *va* in connection with other consonants. In the following table of the Abyssinian characters the modifications for vowel sounds are shown in the six extra forms of the letter *ha*:

ሀ	ha	ኀ	na	ሐ	za	ሁ	hu
ለ	la	ሐ	ā	ረ	fa	ሢ	hi
ከ	hha	ከ	ka	ፕ	psa	ሣ	hā
መ	ma	ዐ	wa			ሥ	he
ሠ	sa	ዘ	za	ሀ	a	ህ	h, he
ረ	ra	ዐ	ja	ሁ	n	ሆ	ho
ሸ	sa	ዐ	da	ሢ	i	ቁ	qua
ቀ	ka	ገ	ga	ሣ	ā	ኀ	khua
በ	ba	ጠ	ta	ሣ	e	ከ	kua
ተ	tha	ሐ	pa	ሀ	e	ገ	gua
ኀ	cha	ሐ	tza	ረ	o		

The Abyssinians separated words by **·**, sentences by **∴**, paragraphs by **❖** or **∴ = ∴**, and sometimes also by beginning a new line. They borrowed the signs of numbers from the Greeks, introducing slight variations to assimilate them with their own graphic system. The Ethiopic, like most Semitic languages, constructed numerous words out of simple verbal roots, by adding particles, doubling one or more consonants, or changing the vowel sound. Such words formed again the stem of many other derivatives. Time was considered as either complete or incomplete, and accordingly only two tenses are distinguished, the perfect and the imperfect. The latter embraced the present and the future, and inasmuch as that which is thought and willed and that which could be, should be, or would be, fall within these con-

ceptions, the imperfect is also the source of the moods. There are only two, the subjunctive and the imperative. Persons, gender, and number are indicated by pronominal prefixes to a verb in the imperfect tense or in the subjunctive mood, but by suffixes when the verb is in the perfect tense. The prefixes and suffixes used in conjugating verbs are abbreviations of the personal pronouns. Only the masculine and feminine genders are distinguished. The masculine has no special termination. Feminine words end generally in *ât*, which was the original form, or in abbreviations and assimilations of this termination, as *at*, *et*, and *t*. The Ethiopic, like the Syriac, abandoned the dual number. The singular and plural numbers are strictly contrasted; even the collectives are capable of receiving a plural termination, and the external formation of the plural is often substituted by an internal change of vowel. These plural forms, thus internally constructed, admit of a further plural termination, generally feminine. The cases of nouns, as in other Semitic languages, are not fully indicated, only the nominative, genitive, and accusative being recognized. The pronouns comprise demonstratives, reflexives, interrogatives, and personals. The prepositions are frequently appended to pronominal suffixes, and conjunctions are often derived from prepositions, if not from relative or demonstrative pronouns, and are sometimes used as enclitics. The Ethiopic has no article, like all Abyssinian languages with the exception of the Saho. Where in other languages it would be necessary to use an article in order to convey a certain idea, the Ethiopic makes use of relative or demonstrative pronouns. Almost every part of a sentence is subordinate to the verb, even the subject, which is often put in the accusative or is governed by prepositions. Subject and predicate stand side by side without a copulative, and agree in gender and number. The position of the parts of speech in a sentence is not governed by strict rules. The predicate stands generally first, next the subject, and last the object.—The literature of the Ethiopic or Geez is chiefly confined to the service of the church. There are numerous translations of the books of the Old and New Testaments and of foreign theological works. There are also some original theological disquisitions, which bear an unmistakable impress of the phraseology of the Bible. Such independent works date principally between A. D. 1300 and 1600. Books on conjuring, magic, astrology, and medicine were also introduced during this period. Early Ethiopian poetry bears a strong resemblance to the Hebrew psalms, but it fell gradually from Biblical subjects to eulogies of saints, and decreased at the same time in literary worth. There is little of metric construction, and at best only an attempt at harmonizing the verses, but without understanding the principles of rhyme. No native grammar has come down to us; the attempts at Amharic-Ethiopic lex-

icons that have been preserved are all in a very crude condition and without grammatical references.—The European study of the Ethiopic dates from the 16th century. In 1548 Tessa-Zion, an Abyssinian, published a New Testament in Rome; but contemporaneous with him, if not earlier, were Johann Potken, Marianus Victorius, Scaliger, Petreus, Nisselius, Wemmers, and Castellius. Hiob Ludolf is the father of the more accurate knowledge of the language. He published in the latter half of the 17th century a grammar and a lexicon, which are still the standard authority. His works are based on oral instruction received from an Abyssinian, at a time when the Ethiopic was still somewhat in use and a common study. But philological science has made such progress that his labors need remodelling. The Ethiopic languages were subsequently neglected. For 150 years scarcely a text was revised or republished, and only a few Hebrew grammars made an occasional reference to them. In 1823 Hupfeld published *Exercitationes Æthiopice*, giving a new impulse to Ethiopian philology. The principal later works are: F. Tuch, *Commentatio de Æthiopica Lingua, Sonorum Sibilantium, Natura et Usu* (Leipsic, 1854); A. Dillmann, *Grammatik der Aethiopischen Sprache* (Leipsic, 1857); Eberhard Schrader, *De Lingua Æthiopica cum Cognatis Linguis Comparatione* (Göttingen, 1860).—The Amharic language (properly Amharinfa) succeeded the Ethiopic or Geez, of which it is a modification, and enters extensively into the languages of Argobba and Harrar. Amhara, formerly an important province of Abyssinia, is now the seat of several Galla tribes. As a descendant of the Ethiopic, the Amharic is also related to the Semitic; but it has adopted many forms and words from surrounding nations which bear no relation to that family. It is written with the same alphabet as the Ethiopic, with the addition of seven peculiar orders of letters. Its grammatical forms and construction are also very similar to those of the parent tongue, though the verb admits of a greater variety of flexion. It has seven moods: indicative, contingent, subjunctive, constructive, imperative, infinitive, and participial. The simple preterite of the indicative, the compound preterite of the contingent, and the compound preterite of the constructive, are used to express past time. The present indicative, the second or aorist constructive, and the contingent with conjunctions denote the present. The infinitive can be used as a verbal noun, and as such it assumes nominal suffixes, but relates to or acts upon other nouns in a verbal capacity. By the aid of suffixed pronouns and prepositions, the verb is capable of expressing a whole sentence by itself. The verb is generally at the end of the sentence, whether the object be simple or complex. The language is very rich in words, but it has no literature. The earliest work on the Amharic language is Ludolf's *Lexicon Amharico-Latinum* (Frank-

MONOPHYLETIC ORIGIN AND THE DIFFUSION
OF THE
TWELVE SPECIES OF THE HUMAN RACE,
FROM
LEMURIA OVER THE EARTH.

fort, 1698). The Amharic translation of the whole Bible, executed in Egypt by an Abyssinian monk, Abu Rumi or Rüh, a native of Gojam, which was revised and published by the British and foreign Bible society (London, 1841), furnishes more valuable material for the study. Isenberg's "Dictionary, Amharic and English, and English and Amharic" (London, 1841), "Grammar of the Amharic Language" (1842), "Amharic Spelling Book," "Amharic Catechism," "Amharic Geography," "History of the Kingdom of God in Amharic," "Universal History in Amharic," and "Book of Common Prayer in Amharic," constitute the principal publications in the language.—Among the other languages related to Ethiopic, none stands as near as the dialect of Tigré. Around it are grouped the Adari, the Affar, the Somaali, and the Saho dialects, and the languages of the Danakils and the Adaiel, and of the district of Harar. The circle of the languages akin to the Ethiopic is constantly increasing, and indicates an extensive emigration of the Semitic races across the Red sea. These dialects are unimportant. They have no graphic system, and, like all unwritten languages, have undergone numerous changes. The variety of Ethiopic or Abyssinian dialects is perhaps unparalleled.—The best authorities on the languages spoken in the regions of ancient Ethiopia, and of the Ethiopic language in particular, are D'Abbadie, Biot, Dillmann, Franz, Gesenius, De Gobineau, Letronne, Lepsius, Renan, Rigby, Rödiger, Salt, and Schrader. See also König, *Vocabulaires appartenant à diverses contrées on tribus de l'Afrique*, in vol. iv. of *Recueil de voyages*, published by the *société de géographie*. Other vocabularies of Ethiopic languages will be found in Salt's "Voyage to Abyssinia" (London, 1814), and in Dr. G. Schweinfurth's *Linguistische Ergebnisse* (Berlin, 1873).

ETHNOLOGY (Gr. *ἔθνος*, nation, and *λόγος*, discourse), the science which treats of man as a member of a tribe or nation, and of his culture, morals, and language. It is closely allied to anthropology, which treats of man zoologically, and of his physical condition and inherent faculties. Ethnology and ethnography are sometimes used indiscriminately, but the former term is more usual. The terms linguistic and descriptive ethnology have recently been introduced to designate the two main branches of ethnological research. The separation of anthropology from ethnology has also been made recently; but in this article they will be considered together. It was formerly required that an ethnologist should not only be a naturalist, but should be familiar with philology or the science of language, archaeology or the study of human monuments and remains, and physical geography as far as it relates to climatic and kindred influences on the races. From the difficulties inherent in the subject, the science of ethnology long remained in a very unsatisfactory condition.

Now, however, it is considered an entirely distinct science, and anatomy, comparative anatomy, mental and moral philosophy, physiology, psychology, philology, climatology, archaeology, and kindred studies form separate divisions of scientific research. Ethnologists and anthropologists confine themselves now to systematizing the results obtained in all and each of these sciences; the latter striving to establish the relation existing between the various types of man for a classification of the human species into races; the former trying to analyze the natural and artificial forms of man in his social relations, in order to detect the forces which cause divergences and analogies among them, and to build thereon a classification of the human race into tribes and nations.—The ancient writers contributed very little to ethnology. Among the Greeks, Herodotus and Xenophon give a faint idea of the ancient populations; among the Latins, Sallust, Cesar, and especially Tacitus, supply fuller information; yet it is only in comparatively modern times, since the discovery of America, the circumnavigation of the globe, the explorations of Asia, Africa, and the Pacific islands, and the revival of physical and physiological studies, that ethnology can be said to have begun to accumulate the materials necessary for a natural classification of the human races. The most important of the classifications proposed during the last two centuries are the following, most of which, it will be observed, are purely anthropological. Linnæus, in the first edition of his *Systema Naturæ*, makes four divisions of the genus *homo*, founded upon the color of the skin, viz.: 1, European, whitish; 2, American, coppery; 3, Asiatic, tawny; and 4, African, black. The divisions proposed by Buffon were five: the Hyperborean (including the inhabitants of the polar regions and of eastern and central Asia, or Laplanders and Tartars), Southern Asiatic, European, Ethiopian, and American. Blumenbach adopted these, changing the names of some of the divisions, and more accurately defining their geographical distribution. He divided mankind into the five classes of Caucasian, Mongolian, Ethiopian, American, and Malay, founded on the combined characters of the complexion, hair, and skull. Before Blumenbach, Camper, a Dutch anatomist, attempted to classify the races by the shape of the skull and the size of the facial angle. Cuvier compares the areas of the cranium and face sawed vertically on the median line from before backward; according to this measurement, the area of the former in the highest races is four times that of the face, in the negro the area of the face being one fifth larger. The *norma verticalis* of Blumenbach measures the breadth of the skull and the projection of the face, and consists in viewing skulls from behind and above, the eye being fixed on the vertex of each. The comparisons of skulls made by Dr. Morton in his ethnological works are based on

the cubic contents of each cranium, measured by noting the quantity which they will hold of any small granular substance. Cuvier divides mankind into three stocks: 1, Caucasian, with the branches Armenian, Indian, and Scythian or Tartar; 2, Mongol or Altaic, with the branches Calmucks, Kalkas, Mantchoos, Japanese, and Siberians; 3, Negro or Ethiopian. He adopts the ill-chosen term "Caucasian" from Blumenbach. It originated from the prevalent belief at that time that the white races had their cradle in the mountains of Caucasus; as there is no foundation for such a belief, the name has been given up by many modern writers. Fischer, in his *Synopsis Mammalium*, divides man into *homo Japeticus*, with the branches *Caucasicus*, *Arabicus*, and *Indicus*; *H. Neptunianus*, with the branches *Occidentalis* and *Papuensis* (the Malay race); *H. Scythicus* (Calmucks and Mongols), with the branches *Sinicus* and *Hyperboreus*; *H. Americanus* (South American indigenes), with the branch *Patagonus*; *H. Columbius*, the indigenes of North America, eastern Mexico, the Antilles, &c.; *H. Ethiopicus*, with the branches *Caffer*, *Melanoides* (Papuan, Feejeeans, &c.), and *Hottentotus*; and *H. Polynesiensis*, the Alfooroos, Australians, &c. Lesson, in his *Mammalogie*, divides the races, according to complexion, into the white or Caucasian, the yellow or Mongol, and the black or negro stocks. His later arrangement in his *Spécies des mammifères* is the following: 1, the white race; 2, the bistre black or dusky race, including Hindoos, Caffres, Papuans, and Australians; 3, the orange-colored or Malay race; 4, the yellow race, including the Mongolians and Oceanic and South American branches; 5, the red, the North American and Carib races; 6, the black race, including the African and Asiatic negroes, Nigritians, Tasmanians, Hottentots, and Bushmen. The divisions of Duméril are: the Caucasian or Arab-European, Hyperborean, Mongolian, American, Malay, and Ethiopian. Virey makes two species of the genus *homo*: the first with a facial angle of 85° to 90° , including the white Caucasian race, the yellow Mongolian, and the copper-colored American; the second with a facial angle of 75° to 82° , including the dark brown Malay, the black or negro race, and the blackish Hottentots and Papuans. The sections of Desmoulins are: Celto-Scythians, Mongols, Ethiopians, Euro-Africans, Austro-Africans, Malays or Oceanians, Papous, negro Oceanians, Australasians, Columbians, and Americans. Bory de Saint-Vincent amplifies considerably the divisions of Desmoulins, making 15 stocks in three classes, as follows: 1. Races with smooth straight hair, peculiar to the old world, including: 1, the Japetic stock (named from Japetus, whom the ancients regarded as the progenitor of the race inhabiting the West, *audax Japeti genus*, the original seat of which is the mountain chains nearly parallel to lat. 45° N.), the Caucasian, Pe-

lagic, Celtic, Slavic, and Germanic races; 2, the Arabian stock, including the ancient Egyptians, North Africans, and Adamic or Syrian races; 3, the Hindoo stock; 4, the Scythic stock, or Tartars; 5, the Chinese stock; 6, the Hyperborean stock (Laplanders, &c.); 7, the Neptunian stock, including the Malays and Oceanic and Papuan races; 8, the Australasian stock. II. Races of the new world, with straight hair, including: 9, the Columbian stock, the North American races; 10, the American stock, the South American races; 11, the Patagonian stock. III. Crisp-haired or negro races, including: 12, the Ethiopian stock, or black races of central Africa; 13, the Caffre stock; 14, the Melanian stock, or races of Madagascar, Papua, Feejee islands, Tasmania, &c.; and 15, the Hottentot stock. Kant divides man into four varieties, white, black, copper, and olive, corresponding to the Caucasian, Negro, American, and Mongolian. Dr. Prichard, in his "Researches into the Physical History of Mankind" (1826-'47), refers mankind to seven stocks or classes of nations, the principal mark of distinction being the peculiar form of the skull; these are: 1, the Iranian (the Caucasian of previous writers), in the form of the skull and in physical traits resembling Europeans, including some Asiatic and African nations; 2, the Turanian or Mongolian; 3, the American, including the Esquimaux and kindred nations; 4, the Hottentot and Bushman; 5, the Negro; 6, the Papuan or woolly-haired Polynesians; and 7, the Australian and Alfooroo nations. Taking the color of the hair as a principal character, Prichard makes three great varieties: 1, the melanic, with very dark or black hair; 2, the xanthous, with yellow, red, or light brown hair, blue or light eyes, and fair skin; and 3, the leucous, or albinos, with white or pale yellow hair, very soft, fair, and delicate skin, and a red hue to the choroid of the eye. According to this author, examples of these varieties are found in all the races. Martin, in his "Natural History of Man and Monkeys" (1841), divides the human race into the following five stocks: 1, the Japetic, including the European branch, or the Celtic, Pelagic, Teutonic, and Slavic nations; the Asiatic branch, or the Tartarie, Caucasie, Semitic, and Sanskrit nations; and the African branch, or the Mizraimic nations (ancient Egyptians, Ethiopians, Abyssinians, Berbers, and Guanches); 2, the Neptunian, including the Malays and Polynesians; 3, the Mongol, including also the Hyperborean; 4, the prognathous (a term adopted from Prichard), including the Negro, Hottentot, Papuan, and Alfooroo branches; 5, the occidental, including the indigenes of North and South America. Dr. Latham, in his "Natural History of the Varieties of Man" (1850), separates the human family into three primary divisions, the *Mongolida*, *Atlantida*, and *Japetida*. The *Mongolida* inhabit Asia, Polynesia, and America, and are subdivided into: *a*, Altaic *Mongolida*, including the Seri-

form (Chinese, &c.) and Turanian (Mongol) stocks; *b*, Dioscurian Mongolidae (the Caucasian races of earlier writers); *c*, oceanic Mongolidae, including Malays, Polynesians, Papuans, and Australians; *d*, hyperborean Mongolidae, Samoyeds and similar nations; *e*, peninsular Mongolidae, Coreans, Japanese, and the nations of the islands and peninsulas of N. E. Asia; *f*, American Mongolidae, the Esquimaux and American Indians; *g*, Indian Mongolidae, in Hindostan, Cashmere, Ceylon, &c. The Atlantidae inhabit Africa and S. W. Asia, and are subdivided into: *a*, negro Atlantidae, occupying the central negro area of the continent; *b*, the Caffre Atlantidae; *c*, the Hottentot Atlantidae; *d*, the Nilotic Atlantidae; *e*, the Amazirgh Atlantidae, or Berbers; *f*, the Egyptian Atlantidae; *g*, the Semitic Atlantidae, or Copts, Abyssinians, Arabians, Syrians, Hebrews, &c. The Japetidae inhabit Europe, and embrace: *a*, the occidental Japetidae, the Celts and their branches; *b*, the Indo-Germanic Japetidae, the European and Iranian Indo-Germans. Dr. Pickering, in the "Races of Man, and their Geographical Distribution" (1848), enumerates eleven races, divided into four groups, according to complexion, as follows: *a*. White, including: 1, Arabian, with nose prominent, lips thin, beard abundant, and hair straight and flowing; 2, Abyssinian, with complexion hardly becoming florid, nose prominent, and hair crisped. *b*. Brown, including: 3, Mongolian, beardless, with perfectly straight and very long hair; 4, Hottentot, with negro features, close woolly hair, and diminutive stature; 5, Malay, with features not prominent in profile, darker complexion, and straight and flowing hair. *c*. Blackish brown, including: 6, Papuan, with features as in 5, abundant beard, harsh skin, and crisped or frizzled hair; 7, Negrillo, apparently beardless, with diminutive stature, negro features, and woolly hair; 8, Indian or Telingan, with Arabian features, and straight and flowing hair; 9, Ethiopian, with features intermediate between the last and the negro, and crisped hair. *d*. Black, including: 10, Australian, with negro features, but straight or flowing hair; and 11, Negro, with close woolly hair, flattened nose, and very thick lips. Prof. Agassiz, in the "Types of Mankind," by Messrs. Nott and Gliddon (1854), asserts "that what are called human races, down to their specialization as nations, are distinct primordial forms of the types of man." He makes the following realms: I. Arctic, inhabited by Hyperboreans; II. Asiatic, by Mongols; III. European, by white men; IV. American, by American Indians; V. African, by Nubians, Abyssinians, Foola, Negroes, Hottentots, and Bushmen; VI. East Indian or Malayan, by Telingans, Malays, and Negrillos; VII. Australian, by Papuans and Australians; and VIII. Polynesian, by South sea islanders. In a subsequent work ("Indigenous Races of the Earth," 1857) Nott and Gliddon give an ethnographic tableau in which the races are divided

zoologically according to the eight realms of Prof. Agassiz; they are also grouped physiologically (after Desmoulins, Achille Comte, and O. d'Halley) into 65 families. The same realms have also their corresponding classes arranged linguistically, after Maury, Crawford, Logan, &c., as follows: realm 1, with the Finno-Ugrian, containing 6 groups; realm 2, with the Tartarian, Sinic, North and South Dravidian, containing 5, 6, 4, and 6 groups respectively; realm 3, with the Ugrian, Iberian, Indo-Germanic or Japetic, Semitic, and Hamitic, containing respectively 3, 1, 6, 9, and 4 groups; realm 4, with the northern, central, and southern, containing 6, 4, and 4 groups; realm 5, with the Atlantic, Mandingo, upper Guinean, upper Soodanian, delta of the Niger, basin of the Tchad, central Africa, Senegambian, Guinean, Congo, Madagascar, and Hottentot, containing 4, 9, 3, 4, 3, 1, 2, 4, 3, 8, 1, and 3 groups; realm 6, with the polyglot class, containing 13 groups; realm 7, with the polyglot class, containing 2 groups; and realm 8, with the monoglot and polyglot classes, containing 4 and a single group.—Among the difficulties encountered in ethnology, the first is the important question of the descent of man. Huxley, Wallace, Darwin, Haeckel, and many others have advocated the hypothesis that man is a descendant of an ape-like animal. It is, however, acknowledged that no one of the now living genera of apes was the immediate ancestor of man. The orang has the closest resemblance to man in the convolutions of the brain; the chimpanzee, in the form of the skull; the gorilla, in the development of the hands and feet; and the gibbon, in the construction of the chest. On a voyage around the world with the recent Austrian scientific expedition (1868) Scherzer and Schwarz took numerous careful measurements of the bodies of individuals belonging to different races, and the conclusion arrived at, as given by Weissbach, was that the resemblance between man and apes is not restricted to any particular people, but is traceable in some portion of the body in all nations; that an heirloom of the relationship is owned by every one, and that even Europeans cannot claim exemption from it. (See EVOLUTION.) The question of the unity or diversity of origin of the different races can also be answered only hypothetically. Many believe still in the blood relationship of all human beings, while others are of opinion that each race originated independently. Not all who accept the doctrine of evolution are monogenists; and the polygenists, or those who believe in the plurality of origin of the human race, base their belief on the fact that the languages do not seem to have come from one and the same source. In order to overcome this evidence, it is necessary to accept the doctrine that primitive man was speechless. (See LANGUAGE.) The difficulties in the way of classifying the numerous races or types of man are as great as in the case of animals and plants.

All varieties are connected by numberless forms of transition, and it is impossible to settle beyond all dispute what is genus, and what species; what race, and what variety. Blumenbach's classification, given above, dividing mankind into five races, has been abandoned, because the difference between them is too great. Quenstedt remarks: "If negroes and Caucasians were snails instead of human beings, all zoölogists would agree in classifying them as two different species." The races are generally distinguished either according to the character of the hair, the color of the skin, the form of the skull, or the convolutions of the brain. The latest results arrived at through the measurements and weighings of the brain will be found in the works of Fritsch, Hitzig, and Meynert. It is believed that in the development of the brain, especially of the frontal lobe, may be retraced the history of man, and that skulls of primitive man furnish a clue to the intellectual spirit of primitive ages. This subject is fully treated in Schaaflhausen's *Ueber die Urform des menschlichen Schädels* (Bonn,

1868). The form of the skulls of the first inhabitants of Europe is ably discussed by Virchow, in his work *Die altnordischen Schädel zu Kopenhagen* (1871). Mankind is divided after the shape of the skull into long-headed (*dolicocephali*) and short-headed (*brachycephali*); the negroes and Australians are the strongest types of the former, and the Mongolians of the latter. Between these two extremes are placed the medium-headed (*mesocephali*), as the Americans. In each of these three divisions are further distinguished the *prognathi*, or those having oblique teeth on account of the projection of the jaws; and the *orthognathi*, or those having straight teeth because their jaws project but little. It seems, however, that the labors of the last ten years in measuring and investigating the forms of skulls have not been sufficiently rewarded. A more satisfactory classification is obtained from the character of the hair of the head, which seems to be strictly preserved in each race. The classification made on this basis, combined with the latest results of linguistic research, is given as follows:

CHARACTER OF HAIR.	Species.	Race.	Habitat.	Came from the	Present number in millions.	Origin of language	State of development.

—In order to gain a clear view of the geographical distribution of mankind, it is necessary to go back three or four centuries to the time of the discovery of America and of the Indian archipelago, when the present extensive mingling of species, and especially the

general invasion of the Indo-European races, were not so far advanced. In the following rapid survey of the human races copious references have been made to the latest works of travel. Our space does not permit us to give in detail the customs and morals of each;

we confine ourselves instead to a succinct enumeration of the physical characteristics, the languages, and the habitats. Beginning with the lowest types of man, we must consider first the Ulotriches or woolly-haired men, among whom the Papuans probably resemble very closely the primitive species. They inhabit at present the island of Papua and the Melanesian archipelago. A few are found in Malacca and on the Philippines. The recently extinct race of Tasmanians belonged also to this species. The Malays supplanted the Papuans in the S. E. portion of Asia, and drove them further east. The skin of the Papuans is black, with a slightly brown and occasionally blue tinge. The crisp hair grows in tufts, is wound spirally, and often more than a foot long, forming a tall woolly peruke. The forehead is narrow and flattened, the nose turned up and large, and the lips thick and broad. The Papuans differ greatly from their neighbors the Malays and Australians, for which reason they are generally classified now as a distinct species. Their dwellings resemble the lake dwellings recently discovered in central Europe. (See Semper, *Die Philippinen und ihre Bewohner*, Würzburg, 1868). The Hottentots are closely related to the Papuans, having like them hair in tufts. The females of both species are very fat around the loins. The skin of the Hottentots is yellowish brown; the face is exceedingly flat; the forehead and the nose are very small; the nostrils large; the mouth very broad, with thick lips; chin small and pointed. It is believed that the Hottentots occupied for some time the whole of S. E. Africa; they inhabit now only the most southern portion. The species is rapidly decreasing, and of the Hottentots proper only two tribes still exist, the Korana and the Namaqua. The Bushmen, who belong to the same species, live in the mountain regions of the interior of Capeland. The language is very peculiar, especially on account of the clicking. (See Schmarda, *Reise um die Erde*, 3 vols., Brunswick, 1861.) The Caffres have also crisp hair, not in tufts, but fleecy, and the skin runs through all tinges from yellow-brown to brown-black. They differ from the negroes in language and in the form of the skull. The face is thin and long, the forehead high and vaulted, the nose often aquiline, the chin pointed, and the lips are not very thick. The various languages of the Caffre races are retraced to the Bantu language, now dead, of the Hamitic group. This species inhabits equatorial Africa from lat. 20° S. to 4° N. The principal tribes are the Zooloo, Zambesi, Bechuanas or Sechuanas, Herreros, and Congos. They are said to have come from the northeast.—The genuine negro is now carefully distinguished from the Caffres, Hottentots, and Nubians. Only the tribes in the eastern portion of the Sahara, the Soodanese in the south of the great desert, and the population of the west African coast lands, from the Senegal in the north to below the mouth of

the Niger in the south, belong to this species. All the negro races seem to have come from the east. The color of the skin is more or less deep black; the skin itself is velvety, and generally emits a bad odor. The hair resembles that of the Caffres, but the face has a different shape. The forehead is exceedingly flat and low; the nose broad, thick, and little protruding; the lips are puffy and turned up very high; and the chin is very short. The genuine negro has always very thin calves and very long arms. This species separated probably very early into numerous tribes, inasmuch as the many totally different languages spoken by them cannot be retraced to the original tongue. The migrations of the African races so far noticed are due in part to the slavery practised among them, compelling the weaker tribes to move if possible beyond the reach of the stronger. They lived undoubtedly much further north at a very remote time; but the immigration of the Mediterraneans (Caucasians), and especially of the Hamites, across the isthmus of Suez, compelled them to cede their original habitation to the superior foreigners. Bearing in mind the age of the Egyptian empire, and the time previously needed for its establishment, it is considered probable that the Hamitic invasion took place about 6000 B. C. (See AFRICA, LANGUAGES OF; Barth's "Travels and Discoveries in North and Central Africa," 1855-'8; Bleek's "Grammar of South African Languages," London, 1869; Duveyrier, *Exploration du Sahara*, Paris, 1864 *et seq.*).—Among the eight species of the branch of smooth-haired men, the Australians or Australian negroes occupy the lowest rank, and seem to inhabit only the large island of Australia. They resemble the negroes in having a black or brown-black skin, a flat and retreating forehead, a thick nose, and puffy lips, and in the almost total want of calves. Their hair is either quite straight or somewhat curly. It is possible that they are related to the Dravidas. They are grouped into North and South Australians in accordance with the latest linguistic researches. (See AUSTRALIA; Christmann's *Australien, Geschichte der Entdeckungsreisen und der Kolonisation*, Leipzig, 1870.) The Malays are ethnologically of great importance, though not very numerous. High authorities consider it certain that the forefathers of the Malays, called Pro-Malays, were the ancestors of most of the nations of Asia, Europe, and America. The modern Malays comprise three races far distant from each other. The Sundanese inhabit Malacca, the Sunda archipelago, and the Philippines; a branch of them is found on the island of Madagascar, and another is scattered over the Polynesian archipelago. The Malays are very fond of navigation, which explains the great territorial extent of the species. Their early habitat was probably the S. E. portion of the Asiatic continent, whence they advanced toward the east and south, pushing the Papuans before them. They

are physically very similar to the Mongolians and Mediterraneans. The head is generally short, though sometimes of considerable length. The hair is smooth and straight, but occasionally curly. The skin is brown, but frequently with a yellow, and also with a ruddy tinge. The face is broad, the nose well developed, and the lips are thick; but the eyes are not quite as small and oblique as those of the Mongolians. Wallace measured several crania of the species so far noticed, and, as the following table shows, the difference between the Malays and Polynesians is not very great, while it is quite large among the others:

NUMBER OF CRANIA.	Capacity.	Proportion of width to length.	Proportion of height to length.
88 Malays (66 male).....	60 to 91	70 to 92	72 to 90
28 Papuans (23 male).....	66 to 80	65 to 85	71 to 85
156 Polynesians (90 male).....	62 to 91	69 to 90	68 to 88
23 Australians (16 male).....	59 to 86	57 to 80	64 to 80
72 Negroes (33 male).....	66 to 87	64 to 83	65 to 81

(See Wallace, "The Malay Archipelago," London, 1869; Bleek, "Handbook of African, Australian, and Polynesian Philology," 3 vols., London and Cape Town, 1858-'63; Friedmann, *Die Ost-Asiatische Inselwelt*, Leipsic, 1868.)—Mongolians are all the inhabitants of the Asiatic continent, with the exception of the Hyperboreans in the north, a few Malays in the southeast, the Dravidas in Further India, and the Mediterraneans in the southwest. The species is represented in Europe by the Finns and Lapps in the north, the Osmanlis in Turkey, and the Magyars in Hungary. The color of the skin is yellow, with either a white or a brown tinge; the hair is straight and black; the head is either short or medium in size, long heads being rare; the face is round; the eyes are small, and often oblique; the cheek bones protrude; the nose is broad, and the lips are thick. The languages of the Mongolians can be retraced to one primitive tongue, which separated at a very remote time into two main branches: the monosyllabic languages of the Indo-Chinese, and the polysyllabic languages of the other Mongolian races. The Thibetan, Burmese, Siamese, and Chinese belong to the former. The polysyllabic Mongolians are divided into three races: the Coreo-Japanese, comprising the Koreans and the Japanese; the Altaians, including Tartars, Kirghiz, Calmucks, and Tungusians; and the Uralians, with the Samoyeds and Finns. Kindred to the last named are the Magyars of Hungary. The Arctic or polar races also seem to descend from the Mongolians. They include the inhabitants of the arctic regions of both hemispheres: the Esquimaux proper and Greenlanders in North America, and the Hyperboreans in N. E. Asia. Acclimation transformed these races so peculiarly as to render it natural to classify them as a separate species. They are low in stature; their heads are medium-sized, and occasionally

long; their eyes are small and somewhat oblique; their cheek bones protrude; their mouths are large; their hair is straight and black. The color of the skin is more or less brown, sometimes with a white or a yellow tinge, like the Mongolians, and sometimes with a ruddy tinge, like the Americans. Their languages differ from the American and Mongolian. The Americans or redskins were the only inhabitants of America at the time of its discovery. The two preceding species are the nearest related to them. The head is generally medium-sized, rarely short or long; the forehead is broad and low; the nose large, protruding, and often aquiline; the cheek bones are prominent, and the lips rather thin; the hair is straight and black; the color of the skin is ruddy, becoming sometimes copper-colored, sometimes whitish, sometimes yellow-brown, and sometimes olive-brown. The numerous languages differ from each other considerably, but are essentially uniform in structure. (See AMERICAN INDIANS, and AMERICAN INDIANS, LANGUAGES OF.) It is probable that America was first peopled by Mongolians, who entered over the N. N. E. point of Asia, and from whom also the Arctic probably descend. It is not unlikely that Polynesians also entered America from the west.—The three species still to be noticed, Dravidas, Nubians, and Mediterraneans, have many characteristics in common, which separate them entirely from the others. The most noticeable feature is the development of a strong beard, which is either entirely wanting or but little developed in the other species. The hair is not quite as straight and smooth, but always more or less curly. The oldest of the three species are undoubtedly the Dravidas, who seem to have occupied the whole of India from Cape Comorin to the source of the Ganges, and to have spread as far as Beloochistan. Pushed by the Aryans or Indo-Europeans, they retired further south; they inhabit at present only the southern portion of the Indian peninsula and the island of Ceylon. The Dravidas resemble in some points the Australians, Malays, and Mongolians, as well as the Mediterraneans. The color of the skin is shaded from light brown to dark brown; the hair is neither straight nor woolly, but more or less curly, and the beard is well developed; the face is oval, the forehead high, the nose prominent and thin, and the lips are not thick. Their language is now strongly intermixed with Indo-European elements, but seems to descend from a peculiar primitive tongue. (See Caldwell, "Comparative Grammar of the Dravidian Family of Languages," London, 1856; Schlagintweit-Sakunlinski, *Reisen in Indien und Hoch-Asien*, 3 vols., Jena, 1869-'73 *et seq.*).—The Nubians include not only the Shangallas and Dongolese, but also the Foolaas must be counted as such. The Nubians proper inhabit the regions of the upper Nile: Dongola, Shangalla, Barabra, and Kordofan;

the Foolaahs moved further west, and inhabit now a broad district south of the western Sahara, between the Soodanese in the north and the Nigritians in the south. The Nubians and Foolaahs are generally classified either with the negroes or with the Hamitic races, and accordingly as Mediterraneans; but their peculiarities are great enough to constitute them a distinct species. The color of the skin is a yellow-brown or red-brown, and but seldom dark brown or black. The hair is not woolly, but generally curly, though frequently quite smooth; it is either dark brown or black. The growth of the beard is much fuller than with the negroes. The oval face gives them a Mediterranean type. The forehead is high and broad; the nose prominent and not flat; the lips are not puffy; and the languages spoken by the Nubian races have no connection with the tongues of the negroes proper. (See Arnaud d'Abbadie, *De l'Afrique centrale, ou voyage de S. A. Mohammed Saïd Pacha dans les provinces du Soudan*, Paris, 1857; and Antoine d'Abbadie, *Géodésie d'Éthiopie*, Paris, 1860-'63, which contains a number of Nubian vocabularies.)—The Mediterraneans have always been considered the best developed and most cultivated species. They were formerly classified as Caucasians, but the term was abandoned on account of the insignificance of the proper Caucasian branch, and Mediterranean was substituted because the most important races of this species flourished first on the shores of that sea. The Mediterraneans are now scattered over the whole world, and as a species they have no equal physically and mentally. The skin is as a rule of a light color, but appears in all tinges from a pure white or a ruddy white, through yellow and yellow brown, to dark and even black brown. The hair is generally rich in growth, and more or less curly, and the beard is fuller than with any other species. The skull is rather broad, and medium-sized heads are more common than others. No other species has an equally symmetrical development of the body. The languages of the Mediterranean races have not yet been retraced to a single primitive tongue; and at the present stage of philology four distinct languages are accepted as the earliest known antecedents of the languages now spoken. In harmony with this result, it is still necessary to divide the Mediterranean species into four races, which are only connected by the roots. Two of these races, the Basques and the Caucasians, are represented by only very small remnants. The Basques formerly inhabited the whole of Spain and the south of France, but are now reduced to about 800,000, dwelling near the northern coast of Spain, at the foot of the bay of Biscay, and a few on the French frontier. (See BASQUES.) The remnants of the Caucasian race are now confined to the Caucasian highlands. Their language, as well as that of the Basques, has no similarity with either the Aryan or the

Semitic tongues. (Consult Cuno, *Forschungen im Gebiete der alten Völkerkunde*, Berlin, 1871 et seq.). It has been attempted to prove that the Semitic and Aryan languages come from one common stock, as by Delitzsch in his *Studien über indo-germanisch-semitische Wurzelverwandschaft* (Leipsic, 1873); but the evidence is not quite sufficient. The two races must have separated at a very remote period. The Semitic race divided very early into the Egyptian and the Arabian branch. The Egyptians or Africans, also called Dyssemites, are by some entirely separated from the Semites, with the designation of Hamites. They embrace the ancient population of Egypt; the large group of Berbers who now inhabit the whole of North Africa, and formerly inhabited also the Canary islands; and finally the group of Ethiopians, Bedshas, Gallas, Danakils, Somaui, and other tribes, who people the coastland of N. E. Africa as far as the equator. The Arabian or Asiatic branch, also called Eusemites, and sometimes designated as Semites proper, embraces the inhabitants of the Arabian peninsula, and the highly cultivated group of Hebrews or Jews, and Arameans or Syrians and Chaldeans. The Hymyarites, an offshot of the South Arabians, have peopled Abyssinia and pushed into the adjacent countries. (See Renan, *Histoire comparée des langues sémitiques*, 2d ed., Paris, 1858).—The Indo-European race has surpassed all other races in intellectual development, and separated like the Semites at a very early period into two branches: the Aryo-Romanic and the Slavo-Germanic. The former produced the Aryans in the narrower sense, or Hindoos and Iranians, and the Græco-Romans, comprising the Greeks and Itali, and according to many authorities the Albanese and Celts; the latter the Slavs and Letts, with the Russian, Bulgarian, Czech, Polish, Serb, and Baltic stems, and the Germanic nations, comprising Scandinavians, Germans, Netherlands, and Anglo-Saxons. (See Fr. Spiegel, *Das Urland der Indogermanen*, Leipsic, 1871, and *Eranische Alterthumskunde: Geographie, Ethnographie und älteste Geschichte*, Leipsic, 1871 et seq.).—On the accompanying ethnological chart are shown the supposititious migrations and distribution of the human race from a continent now sunk under the level of the Indian ocean, to which Sclater has given the name of Lemuria. The cradle of the race is not known, and all the locations assigned to it are only hypothetical. Those ethnologists who give a plural origin to mankind account for the present distribution of the races by tracing their migrations to several starting points or primitive homes. The majority of ethnologists adopt, however, the monophyletic hypothesis, and regard the southern part of Asia as the birth-place of man, placing it either in the highlands of the Himalayas, or near the sources of the Oxus and Jaxartes, or between the Euphrates and Tigris, or in the southern part of Arabia,

or on the ancient continent of Lemuria. The chart traces the migrations of races from the last named region, as with a few small changes it can be made to answer all other hypotheses. Benfey, L. Geiger, and other students of the ancient Indo-European languages, have recently advanced the opinion that the original home of the Indo-European races must be sought in Europe, because their stock of words is rich in names of plants and animals, and contains names of seasons, that are not found in tropical countries or anywhere in Asia. But to establish where the Indo-European races were seated at any time, however remote, is not, as many believe, establishing the first home of the Semites, and much less of all mankind. The following table will show the relation which the most important living or historical races hold to each other, according to the more prevalent ethnological views:

ARYANS OR INDO-EUROPEANS.

I. ARYO-ROMANS.

- A. Aryans proper.
 - I. Iranians.
 - II. Indians.
- B. Græco-Romans.
 - I. Old Thracians.
 - a. Greeks.
 - b. Albanese.
 - II. Italo-Celts.
 - a. Itali.
 - 1. Latins.
 - 2. Romans.
 - b. Celts.
 - 1. British.
 - a. Gauls.
 - β. Old Britons.
 - 2. Gael.
 - a. Irish.
 - β. Old Scots.
 - II. SLAVO-GERMANS.
- A. Slavo-Letts.
 - I. Slavs.
 - a. Southeastern Slavs.
 - 1. Russian.
 - 2. Southern Slavs.
 - b. Western Slavs.
 - 1. Czechs.
 - 2. Poles.
 - 3. Serbs.
 - II. Baltics.
 - a. Old Prussians.
 - b. Letts.
 - c. Lithuanians.
- B. Old Germans or Teutons.
 - I. Goths.
 - II. Scandinavians.
- III. Germans.
 - a. Low Germans.
 - 1. Frisians.
 - 2. Saxons.
 - a. Old Saxons.
 - Netherlanders.
 - Low Germans.
 - β. Anglo-Saxons.
 - b. High Germans.

SEMITES.

- I. HAMITES OR DYSEMITES.
 - A. Mesopotamians (extinct).
 - I. Assyrians.
 - II. Babylonians.
 - III. Ancient Phœnicians.
 - B. Ancient Egyptians.
 - I. Copts or Modern Egyptians.
 - II. Ethiopians.
 - a. Bedshas.
 - b. Danakils.
 - 1. Somaulli.
 - 2. Gallas.
 - III. Libyans.
 - a. Berbers (Amazirghs).
 - 1. Tuariks.
 - 2. Kabyles.
 - a. Tuneses.
 - β. Algerians.
 - 3. Shellooks.
 - 4. Guanches.
- II. EUSEMITES, OR SEMITES PROPER.
 - A. North Semites.
 - I. Canaanites.
 - a. Phœnicians.
 - b. Jews (Hebrews).
 - II. Arameans.
 - a. Syrians.
 - b. Chaldeans.
 - c. Samaritans.
 - B. Arabs or South Semites.
 - I. South Arabs.
 - a. Himyarites.
 - b. Abyssinians.
 - c. Amharas.
 - 1. Hararas.
 - 2. Tigri.
 - II. Moors or Koranites.

The prominent races are described in separate articles.—Another question of interest is to determine the period in which man made his first appearance upon earth. Modern geology and archæology have rendered valuable assistance toward its solution, and at the present stage of these sciences it seems most probable that the time of man's advent must be placed in the tertiary or in the beginning of the dilu-

vial age. It is certain that human beings lived in central Europe as early as the latter period. (See *ARCHÆOLOGY, BONE CAVES, GEOLOGY, and LAKE DWELLINGS.*) Concerning the prehistoric races too little is known for a satisfactory ethnological classification of them. Fergusson suggests in his recent work entitled "*Rude Stone Monuments in all Countries*" (London, 1872) an arrangement of these races into five groups, with subdivisions, according to the degree of art exhibited and the material employed in the construction of the primitive sepulchres. They are designated accordingly as either tumulus, dolmen, circle, avenue, or menhir builders. The characteristics of these sepulchral remains are stated in the article *FINDS*.—Besides the works already mentioned, the following are among the most important recent publications on the subject: Lyell, "*The Geological Evidences of the Antiquity of Man*" (London, 1868); Waitz, *Anthropologie der Naturvölker* (5 vols., Leipsic, 1860-'70, continued by Gerland); Hervey Saint-Denys, *Collection ethnographique photographée* (Paris, 1864 et seq.); Carl Vogt, *Vorlesungen über den Menschen, seine Stellung in der Schöpfung und in der Natur* (2 vols., Giessen, 1864); Schleicher, *Ueber die Bedeutung der Sprache für die Naturgeschichte des Menschen* (Weimar, 1865); Bastian, *Die Völker des östlichen Asiens* (6 vols., Leipsic and Jena, 1866-'71), and *Die Rechtsverhältnisse der verschiedenen Völker der Erde* (Berlin, 1872); Lubbock, "*Prehistoric Times*" (London, 1867), and "*The Origin of Civilization and the Primitive Condition of Man*" (1870); Denison, "*Antiquity of Man*" (London, 1868); Haeckel, *Ueber die Entstehung und den Stammbaum des Menschengeschlechts* (Berlin, 1868); Friedrich Müller, *Ethnographie: Reisen der Fregatte Novara, Anthropologischer Theil* (Vienna, 1868), and *Allgemeine Ethnographie* (1873); Baldwin, "*Prehistoric Nations*" (New York, 1869); Mme. Clémence Royer, *Origine de l'homme et des sociétés* (Paris, 1870); Büchner, *Die Stellung des Menschen in der Natur, in Vergangenheit, Gegenwart und Zukunft* (Leipsic, 1870); J. G. Wood, "*The Natural History of Man*" (London, 1870); Charles Darwin, "*The Descent of Man*" (2 vols., London, 1871); Edward B. Tylor, "*Primitive Culture: Researches in the Development of Mythology, Philosophy, Religion, Art, and Culture*" (2 vols., London, 1871); Bray, "*Manual of Anthropology*" (London, 1871); and the periodicals, the London "*Journal of Ethnology*," "*Journal of the Anthropological Institute of New York*," and Bastian's *Zeitschrift für Ethnologie* (Berlin.)

ETHYLE (Gr. *αιθήρ*, upper air, and *ἔζη*, material), the name given by Berzelius to what was then a hypothetical body, which he considered, and which has since been proved to be, the base of ether and alcohol; ether being the oxide and alcohol the hydrated oxide of ethyle. It was not isolated during his life, but in 1849

Dr. Frankland obtained it by the action of zinc upon iodide of ethyle at a high temperature. Its formula is C_2H_4 when in combination; but when free it is regarded as the double of this, C_4H_{10} . It is a colorless, inflammable gas, having a slight ethereal odor (of which it would probably be devoid if absolutely pure) and a specific gravity of 2.00394. At a pressure of 2.25 atmospheres, and a temperature of $37^\circ F.$, it becomes a colorless, transparent, mobile liquid. It is nearly insoluble in water, but soluble in absolute alcohol. It enters into the composition of a great number of compounds, comporting itself in the manner of a monatomic basylous radical, analogous to hydrogen and potassium, the chloride, bromide, nitrate, &c., containing one atom of C_2H_4 ; the oxide, sulphide, neutral sulphate, and other neutral ethyle salts of dibasic acids containing two atoms of C_2H_4 ; and those of tribasic acids, three atoms of C_2H_4 . It also unites with other alcohol radicals, producing compound alcohol radicals having a composition analogous to ethyle itself.

ETNA (Lat. *Ætna*, probably from Gr. *aitheir*, to burn), a volcano of Sicily, called by the inhabitants of the island Mongibello, from a combination of the Italian *monte* with the Sara-

cenic *jebel*, also meaning mountain. It rises from the E. coast of the island, midway between its N. and S. extremities. The port of Catania is on the prolongation of its S. foot, and, as its history shows, is by no means beyond the reach of its devastating lava currents. North of the mountain is the Val di Demone, watered by the river Alcantara; and 30 m. S. of it is the N. margin of the Val di Noto, in which the waters of the Giaretta find their way toward the coast amid the ancient scorice of the great volcano. The country between these rivers is occupied by the mountain with its various ridges, volcanic cones, and deep depressions, which cover altogether an area of about 87 m. in circumference; yet the lava has spread far beyond these limits. In the midst is the apex of the great conical mass, the highest summit, as ascertained by Sir J. Herschel in 1824, being $10,872\frac{1}{2}$ ft., or 10,835 according to a measurement adopted by Petermann in his latest maps. The latitude of the point is $37^\circ 43' 31'' N.$, the longitude $15^\circ E.$ The cone, at the summit of which is the great crater, is in the midst of a comparatively level region, 9 m. in circumference, the highest point being 1,100 ft. below the principal apex. Around the mountain, at its base, is a fertile

Mount Etna from Catania.

and delightful region known as the *regione culta*. Near Catania this is 11 m. broad, till one reaches in ascending the *regione silvosa*, or woody district; but on the N. side the wood skirts the mountain to within half a mile of its foot. This lowest belt is the region of cultivation; towns and villages are clustered upon it; and in the rich soil of the decomposed lava and tufa are flourishing plantations of olives, vines, grain, fruits, and aromatic herbs. Though in the frequent eruptions some of these are often

swept away, or buried beneath the flow of lava, the attractions of the delicious climate, and of a soil so productive, overcome the fears of a people familiar with the danger, and render them comparatively indifferent to the annoyances of the sharp volcanic dust. The woody region encircles the mountain in a belt 6 or 7 m. in width; but the extensive forests are much broken in upon by the ravages of the lava. Here are fine groves of chestnut and cork trees, and in the higher portions pines of great magni-

tude abound, together with oak, beech, poplar, and hawthorn of immense size. The most famous of these trees is the gigantic chestnut tree seen from Aci Reale, which is, however, described by Capt. Smyth as a cluster of what appeared to be seven trees growing together, the largest of which measured 38 ft. in circumference, and the whole 163 ft. This region affords pasturage for many herds and flocks. Its elevation gives it a cooler and more agreeable temperature than that of the lowest belt. At the height of 5,362 ft. is the Goats' cavern or grotto, frequented by these animals in bad weather, and formerly a resting place for travellers, until the shelter known as the English house was built immediately under the cone, at the height of 9,592 ft., at the expense of some British officers who were stationed in Sicily. The upper edge of the woody region is estimated at about 6,000 ft. above the sea. Beyond it is the cold and desolate zone of the mountain called the *regione deserta*. Its surface spreads out in broad tracts, compared to plains, which are rough and black with the naked lava and scoræ, or white with drifts of snow, which perpetually cover the highest summits. These also collect in the crevices and grottoes of this portion of the mountain, and furnish supplies of ice to the inhabitants of the island, and of Malta and the neighboring region of Italy. In 1828, when the whole country was parched with the excessive heat, a quarry of perennial ice was opened under a stratum of lava, so situated that this must have flowed in a melted state at some distant period over the snow, which, as suggested by Sir Charles Lyell, was no doubt protected from the action of the heat by a previous covering of fine dust and scoræ. The great crater is on a mountain of stones and ashes, which rises about 1,100 ft. above its base in this snowy tract. The diameter of its mouth is estimated by different travellers at from $\frac{1}{4}$ to $\frac{1}{2}$ m., and the depth from 600 to 800 ft. Sulphurous smoke and rumbling noises issue from it continually. The view from this summit at sunrise is magnificent. The mountain itself, lying directly beneath the eye of the observer, which can penetrate into the inferior cones upon its flanks, presents the most original feature of the landscape. The cones, however, are best seen from the lower borders of the desert region. Of these secondary volcanoes Lyell enumerates 80 which are of considerable dimensions, and one of these, called Monte Minardo, near Bronte, is 700 ft. high; and the double hill Monti Rossi, near Nicolosi, formed in 1669, is 450 ft. high, with a base 2 m. in circumference. They are produced by lateral eruptions in the desert region or in the wooded belt below. In the latter their height is reduced by the flow of lava from higher sources, which gathers around, and in some instances buries them and even pours into their craters.—The earliest recorded eruption of Etna is one mentioned by Diodorus Siculus, which caused the Sicani to desert its vicinity and

move further to the south. No date is given, but it appears to have happened before the Trojan war. The next are three eruptions referred to by Thucydides, of which, according to his narrative, one was in 475 B. C., one in 425, and one at an earlier time not clearly specified. These, added to the later recorded eruptions to the present time, make about 70 in all. The most important are those of 1169, 1669, 1755, 1787, 1792, 1852, and 1868. An earthquake in March, 1669, destroyed all the houses in the village of Nicolosi, 10 m. from Catania, near the lower margin of the wooded district. Streams of lava not many days afterward broke forth from chasms which opened in different parts of the mountain. These destroyed as many as 14 villages. From a gulf that formed near Nicolosi, sand and scoræ were projected that produced in the course of three or four months the double cone Monti Rossi. A fissure 12 m. long was formed, which emitted a most vivid light, and extended to within a mile of the summit of Etna. Afterward five other parallel fissures opened, which gave forth smoke and loud bellowing noises. These fissures, which were without doubt partially filled with lava, afford an illustration of the manner in which the porphyritic dikes are formed, which are seen cutting the lavas, and projecting in the form of walls from the precipitous sides of the deep valleys of the mountain; and also of the origin of the trap dikes of older formations. By the flow of the lava among the deep caverns within the mountain, its vaulted foundations were melted away, and the crest, rent with numerous fissures, settled into the vacant spaces. To protect the city of Catania, its walls next the mountain had been raised to the height of 60 ft.; but the lava rose steadily till it overtopped the rampart, and poured a cascade of liquid fire into the midst of the houses. Longafterward, when excavated by the prince of Biscari, the solid lava was brought to view, its layers curling over the wall, as if just petrified in their flow. Its rate of progress varied greatly with the consistency of the melted matter and the slope of the surface. The greater part of the 15 m. of its flow to the sea was accomplished in 20 days, but the last 2 m. were only at the rate of 22 ft. an hour. Its surface exposed to the air was a crust of solid rock; through the side walls streams of the fluid lava often burst out, and by excavating into the great current at suitable places the flow might be diverted in new directions. Attempts to do this by some of the inhabitants of Catania, to protect their town, were opposed with arms by the people of Paterno, as the new current threatened to bring destruction upon their habitations. In some places hills of older lava were melted into the flowing stream. In others the cooling matter taking an arched form protected objects on the surface by enclosing them in grottoes of lava. Thus were preserved many valued articles from one of the churches of Mompigliere,

afterward obtained by excavating 35 ft. into the solid lava. This lava current was so hot at Catania eight years after it entered the town, that it was impossible to hold the hand in some of the crevices. The great lava current as it flowed into the sea had spread over a width of 600 yards, and its depth was estimated at 40 ft. The water was thrown into violent commotion. Sounds louder and more terrific than peals of thunder were constantly sent forth, and the light of the sun was darkened by the clouds of vapor. The fish were destroyed along the coast, and many months passed before the water became again clear and transparent.—The eruption of 1755 is remarkable for a great inundation caused by the flow of two streams of lava upon a vast collection of snow. For 8 m. down the flanks of the mountain the torrent poured, sweeping on the loose scoria and blocks of lava, which were deposited in the plains below. The inhabitants believed that the water was discharged from the crater itself, and the stories of its saltiness and of the marine shells contained in it are still found in the popular accounts of this eruption.

ETON, a town of Buckinghamshire, England, on the left bank of the Thames, opposite Windsor, 22 m. W. of London by road; pop. about 3,000. Its college, the most celebrated of English public schools, was founded by Henry VI. in 1440, and endowed by a gift from his own demesne lands and those belonging to some priories whose revenues had been appropriated to religious houses abroad. The original foundation consisted of a provost, 10 priests or fellows, 4 clerks, 6 choristers, a master, 25 poor scholars, and as many poor men, or beadsmen. Henry VI. at the same time founded King's college, Cambridge, to which Eton was to be preparatory. The first stone of the building was laid July 3, 1441. In 1443 Henry VI. increased the number of scholars to 70 and reduced the beadsmen to 13. At present the foundation consists of a provost appointed by the crown, a vice provost, 6 fellows, 2 chaplains called conducts, 10 lay clerks, 10 choristers, besides inferior officers and servants, and 70 scholars, who since the reign of George III. have been called "king's scholars." As Eton was a Lancastrian foundation, it suffered under the rule of the house of York, and was curtailed by Edward IV. of many of its possessions. More fortunate under the Tudors, Eton was specially excepted from the act of parlia-

ment passed in the time of Henry VIII. for the dissolution of colleges and chantries. At this period its revenues were estimated at £1,100. In 1506 the total income was £652. Its present income is about £7,000. The college buildings consist of two quadrangles, built partly of freestone, but chiefly of brick. The scholars on the foundation are lodged and boarded in the college, and by way of distinction are called collegers. They are admissible from the age of 8 to 16, and, unless put on the roll for admission to King's college at 17, are superannuated and obliged to leave at 18. If put on the roll, they may continue till 19. The foundation scholars must be born in England, of parents lawfully married. By the statutes they should be instructed gratis and clothed in some coarse uniform, but in neither of these points are the statutes adhered to. The sum of £6 or £7 per annum is charged to the parents of every foundation scholar who are able to pay it. Every year the 12 head boys are

Eton College.

put on the roll of King's college, but continue at Eton until there is a vacancy or until superannuated. At King's college the Etonians are maintained free of expense, and after three years they succeed to fellowships. On an average four scholars go to King's college yearly. There are also two scholarships at Merton college, Oxford, for foundation scholars who are not elected for King's college. These latter are called *portionists*, or by corruption, postmasters. In 1842 Prince Albert instituted an annual prize of £50 for proficiency in the modern languages. The larger number of Etonians are not on the foundation, and are called oppidans; they do not board in the college. The annual expenses of an oppidan amount to about £150 or £200. The sixth form is the highest in the school, and is limited in number to 22; of these the highest 10 are styled monitors, and the head boy is called the captain. The

classes are divided between the lower and upper school. There are a head master and a lower master, 23 assistant masters in the upper school and 4 in the lower, 6 mathematical masters, and masters of the French, German and Hebrew, and Italian languages. The course of instruction was formerly almost wholly classical; but mathematics and modern languages are now a part of the curriculum. The annual elections take place in the last days of July every year. The usual number of scholars is between 700 and 800. The Eton montem was a peculiar ceremony, formerly biennial, but after 1759 held triennially on Whit-Tuesday, and discontinued since 1844. On this occasion the boys marched in procession to an elevation on the Bath road called Salt hill, under the lead of the head boy of the foundation scholars as captain. Here they spent the day, partook of a bountiful breakfast and dinner, with music and various ceremonies, and collected toll from all spectators and passers-by. The scene was visited by great numbers of people, and even sometimes by the royal family, and the contributions, called salt, have been known to exceed £1,000. After deducting expenses, the remainder was paid over to the captain, who in 1847 was indemnified by the queen for his loss by the omission of the ceremony.—See "History of the School of Eton," by J. H. Jesse (London, 1872).

ETOWAH, a N. E. county of Alabama, intersected by Coosa river; area, about 500 sq. m.; pop. in 1870, 10,109, of whom 1,708 were colored. The Alabama and Chattanooga railroad passes through it. The surface is somewhat mountainous, but the soil is fertile. Forests abound. The chief productions in 1870 were 41,128 bushels of wheat, 181,034 of Indian corn, 16,745 of sweet potatoes, 13,791 lbs. of wool, and 1,383 bales of cotton. There were 923 horses, 4,623 cattle, 4,950 sheep, and 8,649 swine. Capital, Gadsden.

ETRURIA, or **Tuscia**, a division of ancient Italy, bounded W. by the Tyrrhenian sea, and separated on the N. W. from Liguria by the river Macra (now Magra), N. E. by the Apennines from Cispadine Gaul, and E. and S. by the Tiber from Umbria and Latium. It thus embraced the modern Tuscany, and some adjoining territories, and was a fertile and well cultivated country. Its principal mountains were the Ciminus (Monte di Viterbo) and Soracte (Monte di San Oreste). Its chief rivers were the Tiber and the Arnus (Arno); its chief lakes the Thrasymenus (lake of Perugia), the Lacus Vadimonis (Bassano), the Volsinensis (Bolsena), and the Sabatinus (Brocciano). The testimony of ancient writers, and late discoveries of antique monuments, comprising walls, cloacæ, tombs adorned with sculptures, vases, coins, &c., prove that Etruria was inhabited by a civilized and cultivated people long before the foundation of Rome. They were called Etrusci or Tusc by the Romans, and Tyrrheni or Tyrseni by the Greeks; their

national name was Ras, or with the gentile termination Ras-ennæ. They were distinguished from the Latin and Sabellian Italians, as well as from the Greeks, by their bodily structure, as the sculptures of the Etruscans exhibit only short sturdy figures with large heads and thick arms; by their religion, which was of a gloomy character, delighting in mystical handling of numbers and in horrible speculations and practices; and by the complete isolation of their language. For these reasons no one has as yet succeeded in connecting the Etruscans with any other race. Many dialects have been examined, and sometimes tortured, with a view of discovering some affinity, but in vain. The geographical position of the Basque nation suggested that the Basque language might be cognate to the Etruscan; but no analogies of a decisive character have been brought forward. The scanty remains of the Ligurians, and the sepulchral towers called *nuraghe*, which are found by thousands in the Tuscan sea, and especially in Sardinia, fail to evince relationship with the Tuscan people. As the oldest Etruscan towns lay far inland, it was conjectured that they migrated into the peninsula by land, and perhaps over the Rhaetian Alps, for the oldest traceable settlers in the Grisons and Tyrol, the Rhæti, spoke Etruscan down to historical times, and their name has a resemblance to that of Ras. In strong contradiction to this opinion stands the view that the Etruscan language was Semitic, as well as the ancient tradition that the Etruscans were Lydians who had emigrated from Asia. The latter occurs in Herodotus; but Dionysius asserts that there was not the slightest apparent similarity between the Lydians and Etruscans in religion, laws, manners, or language. It is possible that the belief rested on a mere verbal mistake. The Etruscans or *Turs-ennæ* (which seems to be the original form of the Greek *Τυρσ-ἑννῶι*, *Τυρρῆνῶι*, and of the Roman *Tusci*, *Etrusci*) nearly coincide in name with the Lydian people, the *Τορρήβοι*; and Thucydides confounded their maritime commerce with the piracy of the Lydians, and the Torrebian pirates with the buccaneering Pelasgians. Schwegler's opinion is that the Etruscans were driven into Rætia by the Gauls. Livy's account is also at variance with the opinion given above (Mommson's) that the Etruscans came from the north. The Roman historians generally represent the original Etruscan settlements to have been on the southern or Roman side of the Apennines, and that the Etruscans pushed forward northward to the Alps. It is thus still unexplained how the Etruscans came into Italy. They probably occupied at one time the plains of Lombardy, having subdued the Umbrians, and were then themselves driven out by the Celts or Gauls, about the time of Tarquinius Priscus, when part of them seem to have taken refuge in the mountains of Rætia, and the remainder to have proceeded toward the south.—The few

Etruscan literary remains, as inscriptions on coins and tombs, fail to throw light on the question of their ethnological affinity, as the interpretation of the Etruscan language is still a matter of hypothesis. Dionysius of Halicarnassus and Bochart regard the Etruscan as an aboriginal language; Fréret and Sir William Betham make it Celtic; Ciampi and Kollar, Slavic; Micali, Albanese; Passeri, Gori, and Lanzi derive it from the Greek and Latin, and hold that the Umbrie, Volscie, Oscie, and Samnitic are dialects of it; O. Müller thinks it akin to the Greek; others derive it from Rhætia; others make it cognate to the Basque or the Finnish; and finally, Lami, Pfizmaier, and others, suppose it to be Semitic, a hypothesis which in 1858 J. G. Stickel was thought to have demonstrated to be the truth. In 1873 Prof. Corssen announced that he was about to publish a work on the subject that would show entirely new results. Taylor's "Etruscan Researches" (London, 1874) again endeavors to establish a Turanian relationship. The alphabet is believed to consist of 21 letters, almost coincident in form with the ancient Greek letters, written from right to left, but corresponding in value to those of the Hebrew, though not used as numerical signs. Of several hundred short funeral inscriptions known, 17 have been published as proofs of the Semitic character of the language; some of them are bilingual, with a Latin part giving the name of the deceased. There are also inscriptions on candelabra, drinking cups, and other utensils. Of inscriptions on coins there are but few. Under the Roman emperors the haruspices used Latin versions of Etruscan rituals. Such were the *libri Etrusci*, *Etrusca disciplina* (religion); rituals on the manner of building cities, temples, and altars; on the sanctity of walls and gates; on the *tribus curiæ*, military order, &c.; *fulgurales* and *haruspici*, and the *prodigia*; *Tugetici*, on the ceremonies (*cæremoniæ*, from *Cære* or Agylla) of the earth-born god Tages; *Acheruntici*, on conciliation with the gods, &c. There were also ancient pastoral and augural songs. Varro preserved some fragments, and mentions Etruscan tragedies by Volturnius. The histories to which Varro alludes were probably superstitious inventions similar to those preserved in Plutarch's life of Sulla. In the speech of the emperor Claudius, preserved on bronze plates at Lyons, is cited a version of the adventures of Servius Tullius from Etruscan authorities, and, as Niebuhr thinks, from native annals beginning with the year 407 B. C. It seems, however, that the Etruscan testimony adduced by Claudius is not entitled to credit. The scoffing and jocular Fescennine (so called from Fescennium, a city of Etruria) and Saturnalian verses were also derived from the Tuscans. Cicero, Aulus Gellius, Cæcina, Nigidius Figulus, and some later Romans translated and explained various Etruscan books, of which we have but fragments.—There is no doubt

that the inhabitants of Etruria proper formed a confederacy of 12 cities with adjacent districts, which are supposed to have been the following: Cære (now Cerveteri, Old Cære), Tarquinii (in Roman history the cradle of the Tarquins), Rusellæ (Roselle, remarkable for its monuments), Vetulonia (Torre Vecchia), Volaterræ (Volterra), Arretium (Arezzo), Cortona, Perusia (Perugia), Volsinii (Bolsena), Falerii (Civitas Castellana), Veii (Isola Farnese), and Clusium (Chiusi), the seat of King Porsena. They possessed flourishing colonies in Corsica, Ilva (Elba), and in Campania, where they are supposed to have founded (about 800 B. C.) a confederacy similar to that of Etruria. Their navy was powerful on the Mediterranean at a very early period; a legend mentions an attack upon the Argo, the ship of the Argonauts, by Tyrrhenian mariners. Their commercial vessels visited the eastern shores of the Mediterranean. The inhabitants of Cære were dreaded as pirates. Various remains attest their proficiency in the arts; the frequently occurring representations of festive entertainments, games, races, and dances, accompanied by music, prove their love of recreation, no doubt fostered by the mildness of the climate. They also had national assemblies for religious and political purposes, celebrated at the temple of Voltumna in Volsinii. Their religion resembled in most of its conceptions the polytheism of the Greeks and Romans; it appears, however, to have been deeper, gloomier, and less fanciful than that of the former. The names of many of their deities, who were divided into higher or hidden and other gods, and were believed to reside in the remotest north, seem to mark the transition from the Grecian to the Roman forms. Tina (Jupiter) presides over the council of 12 *consentes* or *complices*, probably personifications of the 12 constellations of the zodiac. They had lunar and solar divisions of time, and cycles of more than a century. Of their numerous sacred books, the principal of which were believed to contain the revelations of the demon Tages, the so-called Acherontic taught how to propitiate the gods, to delay fate, and to deify the soul. Many of their religious rites, those of augury for instance, were adopted by the Romans, who also imitated their games, insignia, and triumphal distinctions. Their priests, called *lucumos*, appear at the same time as heads of noble families and as kings or rulers of cities. They formed the senate of the confederacy, which seems to have consisted of loosely connected independent and sovereign members, at a later period ruled by magistrates chosen annually. The common people were dependent upon the priestly aristocratic families in a kind of feudal clientship, whose forms appear more servile than in the similar Roman institution. Freemen also occur in the history of some of the confederate cities, but as a politically unimportant class.—Walls of cities, sewers, vaults, subterranean tombs, and bridges are the only existing monu-

ments of Etrurian architecture. The Cloaca Maxima at Rome, which is believed to be an Etruscan work, shows that they were acquainted with the use of the arch. The paintings display archaic outlines and an unreal or fantastical coloring. The painted vases usually termed Etruscan, which are found in large numbers in the tombs of Etruria, but also in Campania, Sicily, and Greece, were probably the work of Greek artisans. Authorities differ on the question whether the vases were imported into Etruria or made by Greek workmen settled there. The Etruscans showed great skill in the manufacture of pottery; but the only kinds now assigned to them are the red ware of Arretium and the black ware of Clusium. The specimens of sculpture and carving in marble and wood discovered in the tombs, though very numerous, are not of a very superior order, and the ancient writers do not greatly admire the Etruscans in these arts. But the bronze statues of Etruria were very famous; they filled the temples of Rome, and it is said that the city of Volsinii alone contained 2,000 of them. Some were very large and heavy; Pliny says that the Apollo on the Palatine was 50 ft. high, and as wonderful for its enormous weight as for its beauty. Their greatest fame rests, however, on the artistic designs and skilful execution of decorative objects, as thrones, chariots of state, chandeliers, shields, shells, rings and other jewelry. Etruscan art was imitative rather than creative, and bore at every period the marks of foreign influence, especially Egyptian, Babylonian, and Hellenic.—Some Egyptologists are of opinion that the Takkara nation, mentioned on an inscription among the allies of the Libyans, at the invasion of Egypt during the reign of Rameses III., in the 13th century B. C., were Etruscans, and had a considerable fleet. Other authorities maintain, however, that the Etruscans did not dwell in Italy till a much later period. About 540 B. C. the Etruscans fought jointly with the Carthaginians the first naval battle recorded in the history of the western part of the Mediterranean, at Alalia, against the Phocæans, whom they defeated, gaining thereby possession of the island of Corsica. The subsequent treaties made by the Etruscans with the Carthaginians, reciprocally renouncing piracy in each other's waters, and prohibiting the establishment of colonies on each other's territories, have not been preserved, and Aristotle is the only ancient historian who makes mention of them. The most flourishing period of the history of Etruria comprises some centuries before and after the foundation of Rome. Some believe that the Tarquins were Etruscans, but others hold that they were of Corinthian origin. It does not seem probable that the Etruscans exercised a kind of dominion over their younger neighbor, as Müller, Becker, and Schweigler suppose. According to Livy, whose narrative is now, however, considered legendary, Por-

senas, king of Clusium, made war on Rome for the restoration of Tarquin the Proud, and compelled the Romans to a humiliating treaty. But scarcely had Rome gained peace from him when it commenced a protracted but eventually successful war with another Etruscan enemy, Veii. The distraction of the confederacy by frequent successful and devastating incursions of the Syracusans, by attacks of the Samnites upon its Campanian dependencies, the inroads of the Gauls under Brennus, and the two battles fought near the Vadimonian lake by Quintus Fabius (310) and Publius Cornelius Dolabella (283), finally broke the power of Etruria. The social relation to Rome, into which it entered in 280 B. C., was changed after the social war (90), in reward for its fidelity, into Roman citizenship. Soon afterward Etruria suffered greatly from the revenge taken by Sulla on the partisans of Marius in its cities. Whole districts were given as confiscated estates to the veterans of the dictator, who afterward became the accomplices of Catiline (63–62). Octavianus, too, had his military colonies in Etruria.—Among the numerous writers who have treated of the antiquities of Etruria, the most instructive are Lanzi, Inghirami, Niebuhr, Ottfried Müller, Hey, Wachsmuth, Hormayr, Steub, Dorow, Miceli, Abeken, Seckl, Lepsius, Gerhardt, Denon, Mrs. Gray, Bunsen, Rossignol, Witte, Winckelmann, and Noël des Vergers (*L'Etrurie et les Étrusques*, 3 vols., Paris, 1864). In addition to the authorities mentioned in connection with the theories on the Etruscan language, see Dempster, *De Etruria Regali* (Florence, 1723–'4); Gori, *Difesa dell'alfabeto degli antichi Toscani* (Florence, 1742); Amaduzzi, *Alphabetum Veterum Etruscorum* (Rome, 1775); Vermiglioli, *Saggio di congetture*, &c. (1824); Kollar, *Staroitalia slovjanska* (Vienna, 1853); Mommsen, *Nord-Etruskische Alphabete*; Crawford, "Etruscan Inscriptions" (London, 1873); Uhden, Creuzer, Gesenius, Curtius, Heath, Du-reau de la Malle, Beulé, Levy, Bargès, Renan, and Dr. Frick, in archaeological and philological periodicals.—The history of modern Etruria, a kingdom created by Napoleon in 1801, and given to Louis, crown prince of Parma, ruled after his death by his widow Maria Louisa of Spain as regent, and in 1807 annexed to France as a province, belongs to that of Tuscany (a name derived from the Roman *Tuscia*).

ETTLINGEN, a town of Baden, Germany, at the entrance of the valley of the Alb, 5 m. S. of Carlsruhe; pop. in 1871, 5,092. It has belonged to Baden since 1234, previous to which it was a free city. The town is noted for the large number of interesting Roman antiquities which have been found near it.

ETTY, William, an English painter, born in York, March 10, 1787, died there, Nov. 13, 1849. He was the son of a baker, and at the age of 12 was apprenticed to a printer at Hull, with whom he remained seven years. He studied at the royal academy and as a private pupil of Sir Thomas Lawrence, but was long

unsuccessful. In 1811 one of his pictures was admitted to the academy's exhibition; and in 1821 his "Cleopatra's Arrival at Cilicia," in which the nude female form was depicted with great correctness, and with a voluptuous glow of color, brought him into considerable notice. In 1822 he went to Italy, and spent many months in the study of the Venetian colorists. In 1848 an exhibition of his works was opened in London, prominent among which were the nine great paintings which he considered the triumphs of his artistic career, and in which he says he aimed "to paint some great moral on the heart." They comprise "The Combat," the three "Judith" pictures, "Benaiah, David's Chief Captain," "Ulysses and the Sirens," and the three pictures of "Joan of Arc." Etty is considered one of the chief artists of the modern English school. He wrote an autobiography, which was published in the "Art Journal" for 1849; and his life has been written by A. Gilchrist (2 vols. 8vo, 1855).

ETYMOLOGY. See LANGUAGE.

EU, a town of France, in the department of Seine-Inférieure, on the Bresle, about 2 m. from its mouth in the English channel and 17 m. E. N. E. of Dieppe; pop. in 1866, 4,168. It has a fine Gothic church, with a famous subterranean chapel, and manufactures of lace, serges, and soap. The château d'Eu, in the neighborhood, was one of the favorite castles of Louis Philippe, and it now (1874) belongs to the count de Paris.

EU, Louis Philippe Marie Ferdinand Gaston d'Orléans, count d', a Brazilian general, born at Neuilly, April 28, 1842. He is the elder son of the duke de Nemours, and grandson of King Louis Philippe, and married in 1864 the princess Isabella of Brazil, heir apparent to the throne. He holds the rank of marshal in the Brazilian army. In 1869 he was commander-in-chief of the allied forces in the war against Paraguay, and achieved signal victories which impelled the retreat of Lopez in September, and led to his overthrow and death early in 1870. Previous to leaving Paraguay he proclaimed the abolition of slavery, and a number of slaves were emancipated in Brazil in 1870 in honor of his services.

EUBŒA (Ital. *Negroponte*; Turk. *Egripo*), an island of Greece, the largest of the archipelago, lying in the Ægean sea, between lat. 37° 57' and 39° 3' N., and lon. 22° 48' and 24° 35' E.; area, about 1,400 sq. m.; pop. in 1870, 82,541. It is separated from the coasts of Attica, Bœotia, Locris, and Phocis by a channel called Talanti in its northern part, Egripo in its southern, and about midway, where the coasts are only about 200 ft. apart, the strait of Euripus. At this point it is connected with the mainland by a bridge. On the north the channel of Trikeri separates it from the coast of Thessaly, and on the south the channel of Doro from the island of Andros. Eubœa is long and narrow, being about 100 m. in length, and varying from 6 to 30 m. in breadth. The E.

coast is rocky, irregular, and destitute of harbors. The rocks, which rise almost precipitously from the water, are seldom interrupted by open places, excepting at the N. end. The W. coast has several good harbors. A range of mountains runs through the entire length of the island, culminating in the peak of Delphi, near the middle of the chain, which is 5,730 ft. high. Mt. Kandili, on the W. coast, is 3,967 ft. high; St. Elias, at the S. E. end, 4,840 ft. These peaks are mostly barren. In some parts the mountains are clothed with luxuriant woods, chiefly pines, oaks, and ilexes, with an undergrowth of flowering shrubs, among which are the arbutus, cistus, and oleander. The slopes, which furnish abundant pasturage, are dotted with magnificent trees, and resemble the most beautiful parks in their scenery. There are no rivers, and no streams large enough to admit a boat, but the soil is exuberantly rich and productive. In the north the vine grows luxuriantly, and a red wine of good quality is made in considerable quantities. In the south corn and oil are the principal crops. Fruits also grow in abundance. A number of English and French proprietors, who have settled in the island, have given a favorable impulse to agriculture and done much for the advancement of the people. The principal exports are grain, wine, oil, honey, cheese, cotton, wool, and hides.—The early history of Eubœa is involved in obscurity. In historical times it was inhabited by Ionic Greeks, and was divided between six or seven independent cities, of which Chalcis and Eretria were the most important. They had an extensive commerce, and founded colonies in Macedonia, Italy, Sicily, and the islands of the Ægean. After the Persian war the whole island became subject to the Athenians, who regarded it as the most valuable of their foreign possessions, as it furnished them with corn, timber, and firewood, and with pasture for their horses and cattle. After the battle of Cheronæa (338 B. C.) it formed a part of the Macedonian dominions until after the battle of Cynoscephalæ (197), when its cities formed alliances with the Romans and recovered their independence; but the island was soon incorporated with the Roman province of Achaia. On the dismemberment of the Byzantine empire it fell to the Venetians, from whom it was wrested in 1470 by the Turks, who held it until the Greek insurrection of 1821. It now forms, with the islands of Skyro, Scopelo, Skiatho, and some others, the nomarchy of Eubœa; area, 1,573 sq. m.; pop. in 1870, 82,541.

EUBULIDES OF MILETUS, a Greek philosopher, the best known disciple of Euclid of Megara, flourished about the middle of the 4th century B. C. His life was a struggle against Aristotle, in which by a captious logic he sought to prevail against good sense. A partisan of the Megaric principle, that there is nothing real but what is always one, simple, and identical, he immediately found an adversary in the

founder of the great contemporary school which made experience the condition of science. He attacked the peripatetic doctrine, like Zeno of Elea, by striving to show that there is none of our experimental notions which does not give place to insolvable difficulties. To this end he invented his famous sophisms, of which the following is a specimen: "Some one lies, and says that he lies. Does he lie, or not? By the hypothesis, he lies. Then he does not lie, for what he says is true. Thus he lies and does not lie at the same time, which is contradictory."

EUCALYPTUS (Gr. *εὐ καλύπτω*, well covered), a genus of myrtaceous trees, mostly natives of Australia and the Indian archipelago. The calyx tube is turbinate or campanulate; sepals united in a calyptra or cover, which separates in flowering by a fissure at the base, carrying the petals with it; stamens indefinite, free, with threadlike filaments; anthers versatile, opening longitudinally; ovary 3-4-celled; style filiform, stigma small; seeds usually angular, with a membranaceous testa. While in many species the flowers are small and inconspicuous, they are large in *E. macrocarpa*, and rendered showy by the carmine color of the numerous stamens. Sometimes the eucalypti are found in greenhouse collections, but in pot culture they are kept as mere shrubs. *E. Preissiana* and others are used in Europe for this purpose. The eucalypti are lofty trees, often attaining a height of nearly 250 ft. and a circumference of 70 ft. at the base. The leaves on young trees are opposite, on old usually alternate, coriaceous, entire, and feather-veined. About 100

work. The latter has been raised in southern Europe, and has been largely planted in Algeria and in some parts of British India. It succeeds remarkably in California, where its growth is exceedingly rapid. *E. resinifera* produces a gum much resembling kino, and called Bot-

Eucalyptus Preissiana.

Eucalyptus macrocarpa.

species are recognized, mostly belonging to Australia, where they form 99 per cent. of the forest vegetation, and afford large supplies of honey to bees. *E. gigantea*, the "stringy bark," is a valuable timber tree, and the *E. globulus* or bluegum is even better. The wood is hard and heavy, and well adapted to cabinet

any Bay kino. *E. robusta* has cavities in the stem between the annual rings, which contain a brilliant red or vermilion-colored gum. From *E. mannifera* and *E. dumosa*, during the dry season only, a kind of manna is obtained resembling the officinal manna in its properties, but of a more agreeable taste. *E. piperita* yields an essential oil sold as a medicine in the eastern bazaars. *E. Gunnii* when wounded gives a sap cool and refreshing and slightly aperient; the Tasmanians allow this to ferment, when a pleasant beer results. Almost all the species contain much tannin in the bark, which has been profitably extracted in Australia and sent to England.—A new interest has been given to the genus by the discovery of properties in the leaves and bark of several species resembling those of the cinchona or Peruvian bark, and much more abundant. The *E. globulus* (bluegum) is the species supposed to be most efficacious in marsh and other fevers, and is known in Spain as the "fever tree." Vauquelin obtained in analysis an essential oil containing eucalyptal or eucalypt camphor, and a resin closely resembling resin of cinchona. This extract yielded a substance capable of neutralizing the strong acids, and forming crystalline salts. The sulphate crystallizes in star-shaped crystals like the sulphate of quinia or cinchona, and presents the green coloration on the action of chlorine and ammonia supposed to be peculiar to that salt. The part of the tree most used in medicine is the leaves dried and powdered, although the bark and even the wood have produced favorable results.

EUCHARIST. See LORD'S SUPPER.

EUCHRE, a game of cards, usually played by two or four persons with a pack from which all the cards from 2 to 6 inclusive have been withdrawn. Before commencing the game, the players draw for the deal, which belongs to him who first draws a knave. The pack having been cut by his opponent, or, in four-handed euchre, by his right-hand adversary, the dealer distributes five cards to each player, including himself, commencing at his left, and giving first two and then three, and turns up the 11th card (in four-handed euchre the 21st). The cards have the same relative value as in whist, except that the knave of trumps, called the right bower, is the highest card in the pack, and the other knave of the same color, called the left bower, the next highest; after which come ace, king, &c. Players must in all cases follow suit, and the left bower is invariably to be considered a trump. The game consists of five points. The deal having been completed, the elder hand has the privilege of deciding whether the suit turned up shall be trumps. If he desires to retain it as such, he "orders up" the trump card, in which case the dealer rejects a card from his hand and takes that which he has turned up. In that case, however, the elder hand must take three tricks, constituting a point, or he is, technically speaking, "euchred;" that is, his adversary is entitled to score two points. If, on the other hand, he does not choose to order up the card, he says, "I pass," and the same privilege, with similar conditions, belongs to the next player, and so on. When all the players, including the dealer, have passed, the latter turns down the card, and the elder hand has the privilege of designating the suit which shall be trumps, which must however be another than that previously turned up. If he names a trump, he must score his point or be euchred; and if he is unwilling to take the risk, he passes again. When all the players have passed for the second time, they throw up their cards, and the elder hand succeeds to the deal. A player making all five tricks makes what is called a "march," and is entitled to score two; taking either three or four tricks, he scores but one. In four-handed euchre, in which the players sitting opposite to each other are partners, as in whist, a player having good cards will sometimes desire to "play the hand alone," without the assistance of his partner. If under these circumstances he makes a march, he scores four points; but if euchred, his adversaries score two. The game has been recently modified by the addition of a blank card, called "the yerker" or "little joker," which is the highest in the pack. The game is sometimes played by three persons, in which case any two will combine against the third who may have "taken up" the hand; if they succeed in euchring him, each of them scores two points. This is sometimes called "the cutthroat game," since either of the three players is at any time liable

to be opposed by the other two.—The game of enchre is peculiar to the United States, where it is a universal favorite, being preferred by many to whist. Its origin is not known with certainty, but it is supposed to have been invented in Pennsylvania. It has been recently introduced into England.

EUCLID (Gr. *Εὐκλείδης*), the most celebrated of ancient geometers, flourished at Alexandria in the reign of the first Ptolemy, about 300 B. C. The Arabic historians give many unauthenticated particulars of his life; but it is only certain that he dwelt first in Greece and then in Egypt; and it is probable that he studied at Athens under the successors of Plato, and afterward passed over to Alexandria. There he founded the mathematical school, and was remarkable for his zeal in science, his affection for learned men, and his gentle and modest deportment. Ptolemy having asked him if geometry could not be made easier, he made the celebrated answer that there was no royal road to geometry. To appreciate the merit of Euclid, the state of geometry before him should be considered. Proclus gives the improbable legend that the Egyptians were obliged to invent geometry in order to find again the boundaries of their fields, effaced by the inundations of the Nile. Thence it was brought to Greece by Thales, but it was first raised to a liberal science, and applied to the solution of speculative and theoretical problems, by Pythagoras. Hippocrates was the first to write on elements. Plato, without writing particularly upon geometry, contributed much to its progress by his use of the analytic method, and by the mathematical style of his books; and new theorems were added by numerous lesser philosophers. At the advent of Euclid something had been written on proportion, incommensurables, loci, solids, and perhaps conic sections; and the important property of the right-angled triangle had been discovered. It was the glory of Euclid to unite in a single book all the discoveries of his predecessors, and to add several new ones of his own. He surpassed all other geometers of antiquity in the clear exposition of his theorems and the rigid order of his demonstrations. The "Elements" of Euclid belong both to geometry and arithmetic. They consist of 13 books written by Euclid, and two others written probably by Hypsicles; and they may be divided into four parts, of which the first, comprising the first six books, treats of the properties of plane figures, and presents the theory of proportions; the second gives, in the three following books, the general properties of numbers; the third, consisting of the tenth book, is the development of all the power of the preceding ones, and is occupied with a curious and profound theory of incommensurable quantities; and the remaining books are on the elements of solid geometry, and were so much studied among the Platonists as to receive the name of the Platonic. The best

known of the treatises of Euclid, after the "Elements," is the "Data." By this name are designated certain known quantities which by means of analysis lead to the discovery of other quantities before unknown. One hundred propositions are here collected which are the most curious examples of geometrical analysis among the ancients. Newton highly valued them, and Montucla styles them the first step toward transcendental geometry.—The history of the works of Euclid is the history of geometry itself, both in Christian and Mohammedan countries, until after the revival of learning. They were commented upon by Theon and Proclus, and became the foundation of mathematical instruction in the school of Alexandria. Of the numerous editions and commentaries among the Orientals, that of Nasir ed-Din, a Persian astronomer of the 13th century, was the best. The "Elements" were restored to Europe by translation from the Arabic, the first European who translated them being Adelard of Bath, who was alive in 1180, and who found his original among the Moors of Spain. Campanus, under whose name this translation was printed, was for a long time thought to be its author. The Greek text was first published in 1533 by Simon Grynaeus at Basel, and in subsequent editions was corrected by comparison of manuscripts. Since then the work has been published in a great variety of editions, and translated into all the European and many oriental languages. The English adaptations by Simson and Playfair have been widely received as text books in geometry.

EUCLID OF MEGARA, a Greek philosopher, born about 440 B. C. His first master was Parmenides; afterward he became a devoted disciple of Socrates, at whose death, according to Plato, he was present. But notwithstanding his affection for his second teacher, he retained from the Eleatic school an invincible tendency to subtlety, and it was said of him by Socrates that he knew how to live with sophists, but not with men. After the death of Socrates, his disciples, fearing for their lives, fled from Athens; and at Megara, in the house of Euclid, they found an asylum and a new centre for their studies. Plato himself was an ardent attendant upon Euclid, who taught that the essence of good was unity, unity so entire as to embrace immobility, identity, and permanence. Hence the sensible world has no moral character and no relation to good. He taught also that being consists only in unity, identity, and permanence, and hence the sensible world has no part in existence. Being and good are thus the same thing, namely, unity; good therefore alone exists, and evil is but the absence of existence. It does not follow, however, that there is but a single being and a single sort of good, for unity may be found contained in various things. Euclid expressly taught that in spite of their unity, being and good clothe themselves in

different forms, present themselves under different points of view, and receive different names, as wisdom, God, intelligence, and others. Euclid also anticipated Aristotle in distinguishing the act from the power, and resolved according to his ideas of being the relation between the two.

EUDIOMETER (Gr. *εἰδία*, pure air, and *μέτρον*, measure), an instrument invented by Priestley for determining the proportion of oxygen in the air, in the belief that on this depended its salubrity. Many other instruments have since been invented for estimating the amount of oxygen in gaseous mixtures, and the name is retained for these, though it has no longer its original significance. In the application of the instrument for estimating oxygen, the gas is made to unite with some substance, as phosphorus, introduced into the gaseous mixture, which is contained in the upper end of a graduated glass tube inverted over mercury. The diminution of bulk caused by the absorption of the oxygen indicates its quantity. In other forms a known quantity of hydrogen is introduced, and a mixture fired by an electric spark produced by means of two wires being melted into the sides of the tube and nearly meeting each other within. In this case the tube is made very thick to withstand the explosion. Every two volumes of hydrogen consume one of oxygen, whence the quantity of the latter may be estimated.

EUDOCIA. **I.** A Roman empress, born in Athens about A. D. 394, died in Jerusalem about 461. She was instructed by her father, the sophist Leontinus, in the religion, literature, and science of the pagan Greeks, and was as remarkable for beauty as for learning. Leontinus at his death left her only 100 pieces of gold, saying that the merits of his daughter, which raised her so much above her sex, would be sufficient for her. Having sought in vain from her brothers a share in the paternal heritage, she went with an aunt to Constantinople to solicit the cancelling of the will. She procured an audience of Pulcheria, sister of the young emperor Theodosius II., and regent in his name, who was so charmed by her wit and beauty that she induced her brother to marry her in 421, after her baptism, when she received the name of Eudocia in place of her original one of Athenais. She received the title of Augusta in 423, and requited the unkindness of her brothers by making them consuls and prefects. During the first 20 years after her marriage she took little part in public affairs, which remained in the hands of Pulcheria. She translated parts of the Old Testament into hexameter verses, and a life of Jesus Christ composed in verses taken from Homer is attributed to her. She also celebrated in verse the Persian victories of Theodosius, and the legends and martyrdom of St. Cyprian. She at length, supplanting Pulcheria, ruled the empire for several years. Her court was filled with learned men, with one

of whom, Paulinus, a companion of her early studies in Athens, she cherished an intimacy which roused the jealousy of her husband, and Paulinus was banished to Cappadocia, where he was soon afterward assassinated. The Eutychiean discussion was at this time vexing the church; Pulcheria and Eudocia adopted different views, and in the alternate ascendancy of the two parties, first the former and then the latter was exiled. Eudocia retired to Jerusalem, where the jealousy of the emperor or the vindictive spirit of Pulcheria pursued her, and two priests who shared her exile were slain. The exasperated empress immediately put to death the agent of the emperor; and being now stripped of all the honors of her rank, she passed the remainder of her life in exercises of piety and charity.

II. A Byzantine empress, wife of the emperors Constantine XI. (Ducas) and Romanus IV. (Diogenes). She was married to Constantine before his accession in 1059, receiving the title of Augusta. On his death in 1067 he bequeathed the empire to her and her three sons, binding her by an oath not to marry again. Romanus Diogenes, a popular and able soldier, prepared to seize the throne. Eudocia imprisoned and exiled him, but subsequently married him and made him her colleague. They differed, however, and she again imprisoned him, and during his captivity Joannes Ducas, brother of Constantine, who had been made Caesar, declared Michael Parapinaces sole emperor, and banished Eudocia to a convent near the Propontis. Her husband died from cruel treatment in 1071, and she buried him with great splendor. She appears to have lived many years after this. She compiled a dictionary of history and mythology, entitled *Ἰαννά* (a "Collection of Violets," printed in the *Anecdota Græca*, Venice, 1781).

EUDOXIA, empress of the West, daughter of Theodosius II. and Eudocia, born in Constantinople in 422, died about 463. She was married to her cousin Valentinian III., emperor of the West, after whose death by the hands of emissaries of the senator Maximus for having outraged his wife, she was constrained to espouse the latter. Maximus subsequently had the folly to reveal to her the part which he had taken in the murder of Valentinian, and when the time for vengeance seemed to her to have come she invited to Italy Genseric, king of the Vandals, at whose approach Maximus was murdered. Genseric delivered Rome to pillage, and bore away with him to Africa Eudoxia and her two daughters. They were released after a detention of some years, during which one of the daughters was forced to marry the son of Genseric.

EUDOXUS OF CNIDUS, a Greek natural philosopher, born about 409 B. C., died about 356. He studied under Archytas and Plato, travelled in Egypt, and returned to Cnidus in 359, founded a school, and built an astronomical observatory. Though he seems to have treated the

whole circle of the sciences, he particularly excelled in geometry and astronomy, and is called by Cicero the prince of astronomers. In his astronomical system the earth was the motionless centre of all the celestial revolutions. The movements of the sun, moon, and five planets resulted, according to him, from the combined revolutions of concentric spheres, of which there were three each for the sun and moon, and four for each of the planets. Every planet occupied a part of the heavens by itself, and was surrounded by moving spheres, whose mutually modified motions made the orbit of the planet. He first fixed the length of the year as adopted in the Julian calendar at 365 $\frac{1}{4}$ days, and introduced celestial spheres or globes. In music he studied the numerical relations of sound according to the rapidity of the vibration of the chords. In arithmetic he added three kinds of proportion to the three kinds known before him.

EUDOXUS OF CYZICUS, a Greek navigator of the latter half of the 2d century B. C. Expeditions from Egypt to India had for a time ceased, when he revived them under the reign of Ptolemy Physcon. His bold enterprise in seeking the most direct route to India, to which he made two voyages, and whence he seems to have been the first to bring diamonds, and in attempting to circumnavigate Africa by the west, caused him many persecutions; and his reputation has been obscured by the fables with which Mela and others sought to embellish it.

EUFAULA, a city of Barbour co., Alabama, on the right bank of the Chattahoochee river, at the terminus of the Montgomery and Eufaula railroad, and a branch of the Southwestern railroad of Georgia, 80 m. S. E. of Montgomery; pop. in 1870, 3,185, of whom 1,640 were colored. It stands on a high bluff, 200 ft. above the water, and contains several churches and newspaper offices, and many stores. An active trade is carried on by means of the river, which is navigable to this point from November to June. It is the principal shipping point for the produce of the surrounding plantations, and exports cotton.

EUGENE (FRANÇOIS EUGÈNE DE SAVOIE-CARIGNAN), prince, a general in the service of the house of Austria, born in Paris, Oct. 18, 1663, died in Vienna, April 21, 1736. He was the youngest of the five sons of Prince Eugène Maurice of Savoie-Carignan, count of Soissons, and Olympia Mancini, a niece of Cardinal Mazarin, who was conspicuous for her intrigues at the court of Louis XIV. It was intended by his parents that Eugene should enter the priesthood; but this was against his wish, and he neglected all clerical studies and devoted himself to military reading. Indignant at an attempt of the king to force him into the church, and angry at the treatment to which his mother was subjected by her enemies with the tacit consent of Louis, Eugene left France in 1683, declaring that he would never thereafter enter French territory save as

an enemy. He entered the Austrian service, and made his first campaign against the Turks the same year, so distinguishing himself that he was placed in command of a dragoon regiment. He was present at the battle of Vienna. Further service led to further promotion, and he held the rank of major general at the siege of Belgrade in 1688, where he was severely wounded. Louvois now required all Frenchmen serving in foreign armies to return home, on pain of banishment. Eugene refused to obey, and declaring that he would return to France in spite of the minister, remained in the imperial service, and was rapidly promoted. He was sent to Savoy in command of the Austrian troops furnished to the duke of that country to aid him against France. In this service he fought in several campaigns, and fulfilled the boast he had made at the time of Louvois's order, by invading France with the duke in 1692. He was breveted field marshal, and after his return to Vienna in 1696 was placed at the head of the army in Hungary. Sensible of the folly he had committed, Louis XIV. now made him great offers on condition of his entering the French service. These offers he would not listen to, but took command of an army that was employed against the Turks. He completely outgeneralled the enemy and exterminated their army at Zenta, Sept. 11, 1697, winning one of the greatest victories of that age. A story that the action was fought in violation of orders, that he was afterward placed under arrest, and that it was intended to send him before a council of war, was long current, and has generally been given by all but the more recent historians and biographers; but it has now been proved to be entirely false. He accomplished nothing more of importance in this campaign, and peace was made at Carlovitz in 1699. When the war of the Spanish succession opened in 1701, Eugene was sent to Italy, whither he led his troops by a skilful march across the Tyrolese Alps. Opposed to Catinat, he won great successes. Villeroi, Catinat's successor, he defeated at Chiari, and compelled him to abandon the territory of Mantua. In January, 1702, he attacked the French in Cremona, and, though repulsed, captured their general. In Vendôme he found a worthy antagonist, and they fought the bloody drawn battle at Luzzara, Aug. 15, 1702. Appointed president of the war council, and afterward sent against the Hungarians, Eugene's next important command was in southern Germany, whither he was sent to oppose the united Bavarian and French armies threatening Austria from that direction. Here he first served in company with Marlborough. They fought and won the battle of Blenheim, Aug. 13, 1704, Eugene's part in the action being important. He was then sent again to Italy, and was defeated at Cassano by Vendôme, Aug. 16, 1705, being twice wounded. When the French army passed into the hands of the duke of Orleans and Marshal Marsin, and they

were engaged in besieging Turin, Eugene, at the head of only 30,000 men, attacked their 80,000 men, and defeated them, Sept. 7, 1706. He was wounded in the action, and was rewarded with the government of the Milanese. The next year he again led an army into the south of France, and made an attempt upon Toulon, but failed. He was then employed at the German court in hastening preparations for the next campaign in the Netherlands, now the scene of the chief events of the war, and in that campaign (1708) he helped Marlborough to win the battle of Oudenarde, and took Lille. He also won with him the battle of Malplaquet, Sept. 11, 1709. Much of the ground gained by these victories was lost through the subsequent lukewarmness of the English. On the decline of Marlborough's power in 1711, Eugene visited England, hoping to gain her back to her former position in the alliance, but ineffectually. The peace of Utrecht was concluded in 1713. His own exertions against the French were fruitless, and in 1714 the peace of Rastadt, in negotiating which he played a principal part, put an end to the war between the empire and France. After residing at Vienna for some time, where he was much consulted by the emperor, he was appointed to the command of the army sent against the Turks. He defeated them at Peterwardein, Aug. 5, 1716, with immense slaughter. The next year he advanced against Belgrade, and was there assailed by very superior forces; but at a time when his destruction was regarded as inevitable he assailed the enemy, inflicted upon them the greatest defeat they ever experienced, Aug. 16, and two days later the city surrendered. He was wounded in the battle. In 1718 he hoped to dictate peace at Constantinople, but the treaty of Passarowitz stopped his career of conquest. He was rewarded by a pension, an estate worth 300,000 florins per annum, and the vicar-generalship of Italy, having previously occupied the office of governor of the Netherlands. He held for many years nearly the same position in Austria that Wellington subsequently held in England. Yet he had bitter enemies, toward whom he was very forbearing and patient. In many of his political opinions he was in advance of his age. He saw the error of the house of Austria in encouraging the growth of Prussia, and in conferring on her chief the royal title. He favored an alliance with France, thus anticipating the policy of Kaunitz. He fostered literature, science, and art, and corresponded with Boerhaave, Montesquieu, and Leibnitz, the last named being his personal friend; and he made great collections of MSS., books, and pictures. The last military service in which he was engaged was that which grew out of the war of the Polish succession, in 1734, when he commanded an army against the French on the Rhine. There was not much fighting and no pitched battle. The heir apparent to the Prussian crown, afterward Frederick II., then served under him, and the first

hostile cannon he ever heard, at Philippsburg, were the last heard by Eugene. Frederick pronounced his commander to be only "the shadow of the great Eugene." Nearly two years later Eugene was found dead in his bed one morning, after having played piquet the previous evening. His funeral was one of the most magnificent ever known, 16 field marshals carrying the coffin, and the emperor attending as a private mourner. He was never married.

EUGÉNIE, empress of France. See **BONA-PARTE**, vol. iii., p. 55.

EUGENIUS, the name of four popes. **I. Saint**, born in Rome, died there, June 2, 657. After the banishment of Martin I. in 653, Eugenius was chosen to govern the church as vicar general, and in September, 654, pope, with the consent of Martin, who died in the following year. He labored in vain, like his predecessor, to end the Monothelite controversy. **II.** Born in Rome, died there, Aug. 27, 827. His election, in February, 824, gave rise to a schism that was quelled by the arrival in Rome of Lothaire, son of Louis le Débonnaire. This prince, conjointly with the pope, purified the administration of justice, and corrected many inveterate abuses. A council was convened for the reform of church discipline, which, among other enactments, enjoined on all who had charge of souls to expound the Scriptures to the people and instruct them in all their Christian duties. Eugenius also adopted wise measures for preventing scarcity of food and providing for the sick and poor, whence he was called "father of the people." Some writers have affirmed that he approved of the ordeal by water. **III. Bernardo Paganelli**, born in Montemago, near Pisa, about 1100, died in Tivoli, July 8, 1153. He belonged at first to the order of Cluny, became afterward a follower of St. Bernard, and was by him appointed abbot of the Cistercian monastery of the Three Fountains in Rome. On his accession to the papacy, in February, 1145, he found Rome under the government of a senate, with a president bearing the title of *patricius*. Lucius II. had been killed while attempting to put down a revolt; and Eugenius, unwilling to sanction the new order of things, left Rome, called on the Tiberines for aid, and restored for a time his own authority. He then proceeded to France and Germany for the purpose of organizing the second crusade; held councils in Paris, Rheims, and Treves; visited Clairvaux, where he had been a monk; and in 1149 returned to Italy. The Romans, who during his absence had again established a republic, were forced to submit to the pope through fear of the king of Sicily. Eugenius reëntered Rome, but was driven out after a short time, and spent the remainder of his life in Tivoli. The present division of Ireland into four ecclesiastical provinces is due to this pontiff. It was by his direction that Gratian published the body of canon law called *Decretum*; and at Gratian's suggestion he instituted the academic degrees of bachelor,

licentiate or master, and doctor, to which he attached many privileges. **IV. Gabriele Condulmero, or de' Condulmeri**, born in Venice in 1383, died in Rome, Feb. 23, 1447. His mother was sister to Gregory XII. Gabriele after his father's death distributed 25,000 ducats among the poor, and became a canon in the Celestine congregation of San Giorgio in Alga. On the elevation of Gregory XII. he was induced to go to Rome, where his uncle made him successively chamberlain, bishop of Siena, and cardinal. Martin V. employed him in many important offices, and made him legate (governor) of the marches and Bologna. He was elected pope on the very day appointed by his predecessor for the opening of the œcumenical council of Basel, March 3, 1431. The counsels of the Orsini faction immediately involved him in a quarrel with their hereditary rivals, the Colonnas, the family of Martin V. The civil war which ensued was quelled for a time by the interposition of the emperor Sigismund, and the active support of the Florentines and Venetians. This led him to form an alliance with Venice and Florence against Filippo Maria Visconti, duke of Milan, and his father-in-law Alfonso the Wise of Aragon, both of whom thus became almost his lifelong enemies. The Colonnas, though reduced to temporary submission, were powerfully aided by the Visconti; and their attacks and intrigues were followed up so perseveringly, that the Romans rose against Eugenius in 1434, and compelled him to fly in disguise to Florence. The council of Basel had been convened primarily for the double purpose of reforming the western clergy and healing the Hussite schism, and secondarily for bringing about a reconciliation with the eastern churches. The emperor Sigismund, with all the western princes and prelates, considered the former object as the only one of urgent importance, and approved of Basel for the meeting of the council. The pope, the Greek emperor and his prelates, and the Italian bishops were chiefly anxious for the reunion of the churches, and desired that the council should be held in an Italian city. The small number of prelates present in Basel throughout the year 1431, and some erroneous information given to the pope by a messenger from the council, induced him on Nov. 12 to write to Cardinal Cesarini, the president of the council, ordering him to dissolve it, and to proclaim the indiction of a new council in Bologna for 1433. Cesarini, who had just returned (October, 1431) from Bohemia, where he had witnessed the disgraceful rout of 100,000 imperial troops by Procopius and his Hussites, remonstrated energetically. The council and the emperor had at his suggestion sent a pressing invitation to the Hussite leaders to come to Basel. The change ordered by the pope would destroy the last hope of ending the dreadful religious war which now threatened to devastate all Germany. This opposition of Cesarini was shared by the emperor, by all the western

princes, and particularly by the king of Aragon and the duke of Milan. The members of the council therefore proceeded to act at first independently of the pope, and soon after against his authority and person. (See *BASEL, COUNCIL OF*.) The efforts of Sigismund, who was crowned in Rome in August, 1433, brought about a momentary peace between pope and council; but the revolutionary measures of the latter compelled the pope to dissolve it in June, 1437. An œcumenical council was opened in Ferrara Jan. 10, 1438; on Jan. 27 the pope arrived to preside in person, and early in February the Greek emperor, John Palæologus, and a large number of Greek bishops, arrived in Ferrara, after having been magnificently entertained in Venice. The plague soon breaking out, the pontiff transferred the council to Florence, where on July 6, 1439, was published the decree of union of the Greek and Latin churches. (See *FLORENCE, COUNCIL OF*.) The Armenians, Jacobites, and other eastern communions sent in their adhesion subsequently, either before the end of this council or during that held in Rome in 1444. Meanwhile the refractory prelates of Basel had elected an antipope in the person of Amadeus of Savoy. In 1435 Joanna II. of Naples bequeathed her crown to René of Anjou; but the king of Aragon claimed it as his rightful inheritance, and supported his claim by a powerful armament. The pope, who was the acknowledged suzerain of Naples, rejected both pretenders, and a calamitous war followed between him and Alfonso. It ended by the pope's granting the investiture of the kingdom to Alfonso, and by the latter's aiding the pope to repel the attacks of his own domestic enemies. The pope was thus enabled to reënter Rome Oct. 28, 1443, after nine years' absence; and he immediately convened a new council to meet in St. John Lateran in 1444. A new storm had been threatening Eugenius from the side of Germany. The bishops of Cologne and Treves had been excommunicated and deposed by him for their adherence to the antipope. As they enjoyed the rank of prince-electors of the empire, the whole electoral body took up their quarrel, which was also espoused by the emperor and all the German princes. They had taken at first a position of neutrality between Eugenius and the antipope; but the persistent refusal of the former to revoke his sentence of deposition brought on a threat of recognizing Felix V. as the lawful pope. At length, through the good offices of Æneas Sylvius Piccolomini, afterward pope as Pius II., the difficulty was settled, and all Germany declared formally against the antipope (1447). One of the great anxieties of Eugenius had been the steady progress westward of the Mohammedan power. The letters of the pontiff and the earnest exhortations of his legate Cesarini had induced Ladislas, the young king of Poland and Hungary, to take up arms against the Turks in 1440. The victories of Hunyady at length

forced them to conclude a peace for ten years, and the treaty had been solemnly sworn to on the Gospel and Koran. The pope, however, refused to accept the peace, on the pretext that it had been concluded without his knowledge; a new war was begun, which ended on the field of Varna (1444), where Ladislas perished with 10,000 of his followers. Eugenius declared this disaster to be the bitterest affliction in his troublous life. In 1447, simultaneously with the settlement of the German difficulty, a plan was submitted to the pope by the French king for ending the schism in the church. This was accepted, and caused unbounded joy, in the midst of which Eugenius sickened and died. He has been reproached with his monkish austerity of life, with rashness and inconstancy in many things, and inflexible obstinacy in others. Those most opposed to him allowed him, nevertheless, the praise of an unblemished life. He was, without being learned himself, a most generous patron of learning.

EULER, Leonhard, a Swiss mathematician, born in Basel, April 15, 1707, died in St. Petersburg, Sept. 7, 1783. He was intended for the church, and entered the university of Basel; but the influence of the Bernoullis diverted his attention to philosophical pursuits. At the age of 19 he graduated, after having already attracted the notice of the French academy of sciences by a memoir upon some points of naval architecture. In the following year he went to St. Petersburg, where after several disappointments Daniel Bernoulli obtained for him the professorship of natural philosophy; and in 1733 he became professor of mathematics. His publications on the nature and propagation of sound, curves, the integral calculus, the movement of celestial bodies, &c., had gained him wide reputation; and in 1741, at the invitation of Frederick the Great, he left St. Petersburg for Berlin, where he remained 25 years. During this time he continued to hold his Russian appointments, and even drew a portion of their salary, receiving at the same time from all parts of Europe the most flattering marks of respect. When the dominions of Frederick were invaded by a Russian army in 1760, and a farm belonging to Euler was laid waste, the empress Elizabeth immediately reimbursed his losses. These generous acts, among other motives, induced him to accept an invitation from the empress Catharine II. to return to St. Petersburg in 1766. He had during some years previously suffered from weakness of the eyes; and soon after returning to Russia he became so nearly blind as to be able only to distinguish very large chalk marks on a blackboard. The affection was the consequence of fever brought on by a calculation, for which his fellow academicians demanded four months, but which Euler completed in three days. He continued almost blind during the remainder of his life; but by constant exercise he acquired a power of recollection of mathematical formulas and figures almost incredible. Some of his most

valuable works were composed after his loss of sight; among them, his "Elements of Algebra" and "New Theory of the Motions of the Moon." In more than 50 years of incessant labor he composed 30 separate works, chiefly in Latin, and more than 700 memoirs or treatises. The whole could not be contained in less than 40 large 4to volumes, and embrace every existing branch of mathematics, and almost every conceivable application of them. To Euler belongs the credit of improving the analytic method, according to the system of Leibnitz and the Bernoullis, and of uniformly applying it to scientific investigations. Nor was he less remarkable for his popular expositions of the principles of his favorite science. His "Letters to a German Princess," which have been translated into English, and several times reprinted, throw a clear light on the most important facts in mechanics, optics, acoustics, and physical astronomy, and, though to some degree superseded by the progress of modern discovery, will always remain a model of perspicuous statement and felicitous illustration. His "Introduction to Algebra," translated by Prof. Farrar of Harvard college as preliminary to the Cambridge course of mathematics, has never been surpassed for its lucid and attractive mode of presenting the elements of that science. Euler was a man of simple, reserved, and benevolent mind, with a strong devotional sense and religious habit. He undertook to prove the immateriality of the soul, and had the courage to defend revelation at the court of Frederick II. He was twice married, his second wife being the aunt of his first, and had 13 children, only four of whom survived him. The eldest son was his assistant and successor at St. Petersburg, and the second was physician to Catharine II.

EUMENES, a general of Alexander the Great, and one of his successors, born at Cardia, in the Thracian Chersonese, about 360 B. C., put to death in Gabiene, Elymais, in 316. He attracted the notice of Philip of Macedon, who made him his private secretary, and he held the same office under Alexander. When Alexander married the daughter of Darius, he gave to Eumenes Artonis, daughter of Artabanus. He was at enmity with Alexander's friend Hephæstion, yet maintained his influence, and was ultimately appointed a commander of the cavalry. After the death of Alexander, he at first took no part in the discussions of the Macedonian generals, knowing their jealousy of his Greek birth; but subsequently he reconciled the opposing parties, and in the division of the satrapies obtained the government of Cappadocia, Paphlagonia, and Pontus. These provinces had never been conquered, and Antigonus and Leonnatus were appointed to reduce them for him. Antigonus disdained compliance, and Leonnatus went to Greece to carry out plans of personal ambition, having tried to persuade Eumenes to join with him. Eumenes, however, exposed the

schemes of Leonnatus to Perdicas, and the latter subdued his provinces for him, and gave him the chief command in Asia. Eumenes now subdued Neoptolemus, who had revolted from him, and defended Asia Minor against Craterus in a decisive battle (321), in which the latter fell. Perdicas having fallen in a revolt of his own troops, a general assembly of the Macedonian army condemned Eumenes to death. Antigonus marched against him, defeated him in Cappadocia (320), and blockaded him in the fortress of Nora. The death of Antipater changed the aspect of parties, and Antigonus sought the alliance of Eumenes; but the latter, having been allowed to leave his mountain fortress, accepted overtures offering him by royal authority the supreme command in Asia. Eluding Antigonus, he joined the army in Cilicia, and to avoid the jealousy of the generals set up in a tent the throne, crown, and sceptre of Alexander, before which the councils of war were held, as though in the presence of the deceased monarch. He advanced into Phœnicia, but retired before the combined fleet and army of Antigonus, and took up winter quarters in Babylonia. The armies subsequently met on the confines of Gabiene in two pitched battles, with no decisive result; but Eumenes was sold by his own troops to Antigonus, who slew him.

EUMENIDES (called also Erinnyes, and by the Romans Furia and Dira), the avenging goddesses of the Greek mythology, daughters of Night, and tormentors of the wicked both in the upper and the lower world. The Greeks dreaded to call them by an appropriate name, and therefore addressed them euphemistically as the Eumenides, or gracious goddesses. They seem to have been originally a personification of the curses pronounced upon a criminal, and are represented by Homer as resting in the depths of Tartarus till the condemnation of some person for violated pious or hospitable duties wakes them into life and activity. They then pursue the offender with the relentlessness of fate, chasing him from place to place, allowing him no peace nor rest, moved by no supplications, and supported by the goddess of justice, whose ministers they are. As described by Æschylus, snakes instead of hair enveloped their heads, their eyes were bloody, their faces black and full of hatefulness, and they bore torches and daggers in their fleshless hands. In the later poets wings were added, and their number was reduced from an indefinite number to three, bearing the names of Tisiphone, Alecto, and Megæra. The terrific drama of Æschylus entitled "Eumenides" is said to have frightened several Athenian matrons into premature labor, and in subsequent representations upon the stage and in art their appearance was greatly softened down.

EUNAPIUS, a Greek sophist, physician, and biographer, born in Sardis, Lydia, A. D. 347, died about 420. He was an adversary of Christianity, and an enthusiastic admirer of the em-

peror Julian. At the age of 16 years he went to Athens, where after four years' study he was admitted to know the secrets of the theurgic doctrine of Iamblichus, and was initiated into the Eleusinian mysteries. He returned to Sardis as a teacher of rhetoric, and studied medicine. One of his works remains, a book entitled "Lives of the Sophists and Philosophers," which gives the history of philosophers, physicians, and rhetoricians, and of nearly all known in science and letters from the beginning of the 3d to the end of the 4th century. The best edition is that of Boissonade (2 vols. 8vo, Amsterdam, 1822).

EUNOMIUS, a heresiarch of the 4th century, a native of Dacora in Cappadocia, who studied theology under the Arian teacher Aëtius, and was made bishop of Cyzicus about 360. His opinions were a logical exaggeration of Arianism. He was soon deposed from his bishopric, resided at Constantinople during the reigns of Julian and Jovian, and at Chalcedon during that of Valens; was banished by the last named, but soon recalled; was again banished by Theodosius the Great to Halmiris in Moesia, driven thence to Cæsarea, and at length permitted to return to his native village, where he spent the remainder of his life, and died at an advanced age. His works were ordered by imperial edicts to be destroyed, but there remain of them a "Confession of Faith," which was presented to the emperor Theodosius at Constantinople in 383, and an "Apologetic Discourse," a famous treatise, of which St. Basil wrote a refutation in five books. His disciples were called Eunomians, and also Anomæans (Gr. *ἀνόμοιος*, dissimilar), because, unlike the Athanasians or Homoousians and the Arians or Homoiousians, they affirmed that the Son and Holy Spirit were neither identical with nor similar in essence to the Father. They acknowledged the Father as supreme, eternal, and distinct; the Son as generated from the Father, and the Holy Spirit as generated from the Son. Like their founder, they were accustomed to subtle speculations upon the divine nature, the incomprehensibility of which they denied. They rejected mysteries, and opposed the honors rendered to martyrs and to the relics of saints.

EUNUCHS (Gr. *εὐνοῦχος*, from *εὐνή*, a bed, and *ἔχειν*, to guard), emasculated men employed in the East from time immemorial to take charge of women. A product of oriental polygamy, jealousy, and despotism, eunuchs were early common in Egypt, Syria, Asia Minor, and the neighboring countries, and were introduced thence into Greece and Rome. Among the later Romans they were admitted into the families of senators and emperors, and by their skill in flattery and intrigue often established their power at court, especially under the Byzantine empire. The Romans ingeniously devised a method of making castration more or less complete. Gibbon affirms that the general history of Persia, India, and

China proves that the power of the eunuchs has uniformly marked the decline and fall of every dynasty. They are still employed in the East as guardians of the harem, black slaves from Africa being generally preferred. The eunuchs of the Turkish harems are mostly made such in Upper Egypt, near Nubia, at a village where the operation of castration is performed by Coptic priests. It is stated that about one in seven of the boys die in consequence of the operation.—The Christian church from the beginning manifested her abhorrence of the practice of mutilating men, excluding eunuchs from orders even before a law to that effect had been promulgated. The ordination of Origen at an advanced age, by the bishops of Cæsarea and Jerusalem, was protested against by his own bishop, Demetrius of Alexandria, on the ground that Origen in his youth had mutilated himself as a safeguard against temptation—a fact which Origen had concealed, but which had become known to Demetrius. This recognition of such an ordination as irregular attested the universal discipline of the church, confirmed by the law enacted by the council of Nice, and observed ever since throughout Christendom. This law was directed more especially at a sect of fanatics called Valesians, from their Arab founder Valesius, who insisted upon this practice of mutilation as a necessary means of salvation. Christian Italy inherited from pagan times the custom of mutilating boys in order to preserve their voice; and down to our days such singers have been much sought for in theatres and churches. Clement XIV., renewing the enactments of several preceding popes, forbade their employment in religious services. Nevertheless, the custom still continued to prevail in Rome itself. (See CASTRATION.)

EUPATORIA (formerly *Kozlor*), a seaport town of Russia, in the government of Taurida, on the W. coast of the Crimea, and on the N. shore of the bay of Kalamita, 38 m. N. W. of Simferopol, and 40 m. N. of Sebastopol; pop. in 1867, 7,730, chiefly Tartars and Caraites. Under the Tartars it was one of the most prosperous and populous towns in the Crimea. Before the Russian occupation of the peninsula, when the name of Eupatoria was given to the town by Catharine II., it had a population of above 30,000. It has a considerable trade in grain, and some trade in hides, butter, wax, &c. The export of salt, which is drawn from adjoining salt lakes, and from which the Tartars formerly derived great profit, has fallen off considerably. Butter, felt stuffs, and the black lambskins known in England as astrakhans, are prepared in the town. The port is shallow, but safe, and never frozen up. The principal buildings are a Greek church, an Armenian church, two synagogues, and several mosques, the chief of which, built by Devlet-Ghiri Khan in 1552, is the finest in the Crimea.—On Sept. 14, 1854, the English and French effected a landing in the bay of Eupatoria, with about 60,000 men.

The town was provided with fortifications by order of Omar Pasha, who was at the head of the Turkish troops in 1855. The Russians made an ineffectual attack on it Feb. 17, 1855. It was evacuated by the allies after the ratification of the peace of Paris, May 30, 1856.

EUPATORIUM. See BONESET.

EUPEN (Fr. *Néau*), a town of Prussia, in the province of the Rhine, capital of a circle of the same name, situated near the Belgian frontier, 9 m. S. of Aix-la-Chapelle; pop. in 1871, 14,696. It has a Protestant and three Catholic churches, a town school of a high grade, an orphan asylum, and a court of primary jurisdiction. It is one of the most flourishing manufacturing towns of the province.

EUPHORBIA, the typical genus of the botanical family *euphorbiaceæ*, or spurge, said to have been so named from Euphorbus, physician to Juba, king of Mauritania. The flowers are monœcious, collected within an involucre often closely simulating a calyx or corolla; male flowers consisting of a single stamen on a pedicel arising from the axil of a minute bract at the base of the involucre; fertile flower solitary in the middle of the involucre, consisting of a three-celled, three-lobed ovary, with a mere vestige of calyx, and borne on a pedicel which finally elongates and inclines to one side of the involucre; styles three, stigmas six. The pod separates into three one-seeded carpels. Plants or shrubs, often with a milky, acrid juice. The leaves are whorled or opposite, and sometimes wanting, the stem being succulent, and the plant assuming the appearance of a cactus. It is a cosmopolitan genus of many and diverse species. Some are commonly cultivated as ornamental plants, as *E. pulcherrima* (*Poinsettia*)

Euphorbia officinarum.

of Mexico, whose floral leaves are 4 or 5 in. long and of the brightest vermilion red; *E. splendens* of the Mauritius, with thick, prickly stems, and cymes of deep red bract-surrounded flowers. The gum resin, *euphorbium*, is gathered in Africa from *E. officinarum* and *E. an-*

tiquorum, and in the Canaries from *E. Canariensis*; it flows from incisions made in the stems, and is extremely acrid, producing violent inflammation of the nostrils in those who handle it. In India this gum is used externally in rheumatism, internally in cases of severe

Euphorbia ipecacuanha.

constipation. *E. Tirucalli* is common near Madras, where it is used for hedging; no cattle will touch the leaves; the fresh juice of this species is used as a vesicant. The roots of many species are emetic. Of our native species, the principal and the only one of general interest is *E. ipecacuanha* (wild ipecac), which was considered by Barton equal in value to the genuine ipecacuanha (*cephælis*), and it possesses the advantage of having no disagreeable taste or smell. *E. lathyris* was one of the plants Charlemagne in his capitularies commanded to be cultivated in all monastic gardens, as its seeds were purgative and known as *semina cataputiae minoris*. It is said that the capsules of this plant stupefy fish; it is well known that *E. Hibernica* and *E. piscatoria* are so used, and so powerful is the former that a small basketful of the bruised plant will stupefy the fishes for several miles down a river. *E. Cattimandu* furnishes a caoutchouc; and notwithstanding the generally poisonous qualities of the genus, *E. edulis* is a pot herb, its acrid qualities being dispelled by boiling. *E. balsamifera* is used in the same way. Many species of euphorbia grow in poor sandy soil, through which the roots penetrate to a depth of several yards. Violent vomiting and purging are often produced in children by eating the seeds of a variegated-leaved euphorbia cultivated as an ornamental plant. The uncertainty of their action forbids their general use as medicine.

EUPHRATES (Turk. *Frat*), the largest river of western Asia. It rises from two chief sources in the Armenian mountains; one of them at Damly, 25 m. N. E. of Erzerum, the other on the northern slope of the Ala Dagh,

near the village of Diyadin, and not far from Mt. Ararat. The former, or Northern Euphrates, has the name of Frat from the first, but is known also as the Kara-su (Black river); the latter, or Southern Euphrates, is not called the Frat, but the Murad Chai, though in reality the main river. Both branches flow mainly W. S. W. and meet at Kieban-Maaden, about lat. 38° 50' N. and lon. 38° 40' E., after a course of respectively 270 and 400 m. The combined stream is here 360 ft. wide, rapid, and very deep. It flows a winding course, mostly S. and S. W., traversing a chain of Mt. Taurus, till it reaches the vicinity of Nizib, where it is deflected S. E., keeps its way without deviation till near its junction with the Tigris, and the united rivers fall, under the name Shat-el-Arab, into the Persian gulf. Its total length is about 1,800 m., its average breadth about 200 yards, and its depth from 12 to 30 ft. The upper part of its course lies amid lofty mountains, and near the village of Pashtash it plunges through a gorge formed by precipices more than 1,000 ft. in height, and so narrow that it is bridged at the top. It then enters the plains of western and southern Mesopotamia, where the swiftness of its current is diminished, and where in ancient times numerous canals extended from its banks to irrigate the neighboring country. It extricates itself from the marshes of Lemlun just before reaching Korna, the point of its union with the Tigris. It is navigable both below and above the cataracts which it forms in the passes of the Taurus, though numerous islands, shallows, and rapids make its navigation in many places difficult. Its waters are subject to periodical increase from the melting of the snow on the mountains along the upper part of its course, and its inundations were anciently of great advantage to the agriculture of the level districts through which it passes. Under the misrule of the Turks, however, the canals and embankments which regulated the inundations have been neglected.—The Euphrates is linked with the most important events in ancient history. It is mentioned in the Bible as one of the four rivers of the garden of Eden, and is often named the great river. On its banks stood the city of Babylon, which was for ages not only the capital of great empires, but also one of the greatest commercial emporiums of the world. Indian and Egyptian merchandise destined for Babylon was transhipped in the port of Gerrha, now Katif, in the Persian gulf, from the large vessels that had made the sea voyage into smaller ones fit for the navigation of the river. Nebuchadnezzar, however, had locks constructed, and dikes raised to contain the waters of the Shat-el-Arab, which allowed vessels of heavy burden to ascend the Euphrates as far as Babylon. It was for a long time the western boundary of the Parthian and the eastern boundary of the Roman empire. The army of Necho was defeated on its banks by Nebuchadnezzar at

Circesium (Carchemish); Cyrus the Younger and Crassus perished after crossing it, the one at Cunaxa, the other at Carrhæ; Alexander crossed it at Thapsacus; Trajan and Severus descended it in fleets built in upper Mesopotamia. In recent times the English have tried to use it as their path of communication with India. For this purpose an expedition was sent from England under command of Col. Chesney, which in 1836 descended the river from Bir and surveyed 509 m. of its course. The steam navigation of the Euphrates, from its mouth to Bir, has since become of some importance. The electric telegraph line from Bagdad to the Persian gulf, which was opened in 1865, skirts the Euphrates as well as the Tigris. It is a singular fact concerning the Euphrates that several thousand years ago the waters do not seem to have reached the sea at all, but were lost in marshes or consumed by irrigation, which was practised on an immense scale under the Babylonian and Assyrian sovereigns. It is certain that at a much later period the Tigris and Euphrates flowed into the sea by distinct channels. Their junction is supposed to have taken place more than 2,000 years ago.

EUPHUISM (Gr. *εὐφύς*, elegant), an affected style of speech which distinguished the conversation and writings of many of the wits at the court of Queen Elizabeth. The name and the style were derived from the "Euphues, the Anatomy of Wit" (1580), and the "Euphues and his England" (1581), of John Lilly, of which Anthony à Wood said: "Our nation is indebted for a new English in them, which the flower of the youth thereof learned." The style of these once famed books, which became the model of the wits and gallants of the time, and was almost regarded as a test of courtly breeding, was characterized by smoothness and verbal elegance, and chiefly by fantastic similes and illustrations formed by attributing fanciful and fabulous properties to animals, vegetables, and minerals. Supported by fashionable sanction, Lilly was for a time esteemed the rival of Demosthenes and Cicero in "all the partes of rhetoricke, in fitte phrases, in pithy sentences, in gallant tropes, in flowing speech." But the applause was not universal. Euphuism is ridiculed in Marston's comedy of "What You Will" and Ben Jonson's "Cynthia's Revels," and is thought to be referred to in the style of Don Armado in Shakespeare's "Love's Labor's Lost." Sir Walter Scott in his "Monastery" makes Sir Piercie Shafton "parley euphuism."

EUPOLIS, one of the six Greek comic poets whom the grammarians of the school of Alexandria judged worthy of a place in their canon, born about 446, died about 411 B. C. He belonged to the old comedy, was a disciple of Cratinus, and composed 17 pieces, seven of which were crowned. He was reputed superior to Aristophanes in elegance, and in bitter and personal jests was the rival of Cratinus. Among the objects of his satire were Alcibia-

des and Socrates, the former of whom, according to one report, exasperated by his attacks, threw him into the sea, where he was drowned. He is also said, with more probability, to have been killed in battle during the Peloponnesian war. The fragments of his plays have been edited by Runkel (Leipsic, 1829), and are contained in Meineke's *Fragmenta Poetarum Comicorum Græcorum* (Berlin, 1839-47).

EURE, a N. department of France, formed by the union of four ancient districts of Normandy, bordering on the departments of Seine-Inférieure (from which it is partly separated by the lower part of the Seine), Oise, Seine-et-Oise, Eure-et-Loir, Orne, and Calvados; area, 2,300 sq. m.; pop. in 1872, 377,874. It has a level surface, naturally divided into six plateaus by the rivers Epte, Andelle, Eure, Iton, Rille, and Charentonne, which flow through it to the Seine; and it presents well cultivated fields and enclosures, fine forests, marshes, and a few hills. The river from which the department has its name flows on the S. E. border, and then mostly parallel with the Seine. Agriculture is carried to a high degree of perfection, and the vine, apple, and pear are objects of special cultivation. Its most celebrated and flourishing cloth manufactories are at Louviers. It has important copper founderies at Romilly, and manufactories of nails, pins, &c. It has considerable commerce, chiefly in its own manufactured and agricultural products. It is divided into the arrondissements of Evreux, Louviers, Pont-Audemer, Bernay, and Les Andelys. Capital, Evreux.

EURE-ET-LOIR, a N. department of France, formed from parts of the ancient provinces of Orléanais, Ile-de-France, and Maine, bordering on the departments of Eure, Seine-et-Oise, Loir-et-Cher, Sarthe, and Orne, and comprised in the basins of the Seine and the Loire; area, 2,268 sq. m.; pop. in 1872, 282,622. Its general aspect is that of a plain, with slight undulations of hill and valley, and its soil is unsurpassed in fertility by any in France. The river Eure, which rises near the W. border in Orne, flows E. and N. through the northern part, and the Loir rises near the centre and flows S. S. W. to the Loire. The climate is mild, with frequent rains in spring and autumn. There are but small remains of the immense forests which formerly covered its surface. Cereals, the vine, prune, pear, cherry, and apricot are cultivated. It has some cloth manufactories. It is divided into the arrondissements of Chartres, Châteaudun, Dreux, and Nogent-le-Rotrou. Capital, Chartres.

EURIPIDES, the last of the illustrious trio of the tragic poets of Athens, born, according to the almost unanimous consent of the ancient authorities, in the island of Salamis, in the 1st year of the 75th Olympiad, 480 B. C., and, as was generally believed, on the very day of the battle of Salamis (Sept. 23). The Parian mar-

ble alone carries back the date of his birth to 485, or the fourth year of the 73d Olympiad. He died in 406. The name Euripides is said to have been bestowed upon him in commemoration of the battle of Artemisium, fought not long before, near the channel of the Euripus. He was the son of an Athenian citizen named Mnesarchus, and his wife Clito, of the deme of Phlya and the tribe Cecropis, or according to others of the deme of Phyle and the tribe Eneis. His parents had left Athens on the approach of Xerxes and his Persian host. The condition of the family was respectable and perhaps affluent, though Aristophanes, in his comic attacks upon the poet, describes his mother as a seller of herbs. Early trained in athletic exercises, Euripides is said to have gained while still a boy the victory in the Eleusinian and Thesean contests; and at the age of 17 he offered himself at the Olympic games, but was not received. For a time he devoted himself to the art of painting, and some of his performances are said to have been exhibited at Megara. He studied rhetoric under Prodicus, the author of the apologue of the "Choice of Hercules," who visited Athens as ambassador of his native city; physics under Anaxagoras, whose opinions gave a coloring to his poetry; and perhaps philosophy under Protagoras. He became an intimate friend of Socrates, who was 11 years his junior. At length, after trying his hand in other pursuits, his natural turn for tragedy manifested itself. His first piece was written at the age of 18, but there is no evidence that it was brought upon the stage. "Peliades," the first of his plays represented in his own name, was brought out in 455. This is not preserved. Fourteen years later, in 441, he gained for the first time the first tragic prize. Ten years after this, in 431, he gained the first prize with the tetralogy, including "Medea," "Philoctetes," "Dictys," and "Theristæ." In 428 he brought out the "Hippolytus;" in 412 "Andromeda;" and in 408 "Orestes." He appears to have carried off the prize but seldom, if we consider the number of his plays—15 times according to Thomas Magister, or five times as others state; while he is said by some to have written 92, and by others 75 pieces, including the satyric dramas or afterpieces with which the tragic trilogy was usually followed. Soon after the representation of "Orestes," Euripides appears to have accepted the invitation of Archelaus, king of Macedon, to take up his residence at that court. He had already held possession of the Athenian stage for more than 50 years, and had written an extraordinary number of masterpieces, when he went to try the uncertain experiment of residence at a foreign court; but there were some powerful reasons which urged him to this step. The rivalries in his art, and still more the attacks to which he exposed himself by the freedom of his philosophical and religious opinions, proba-

bly embittered his life at Athens. According to tradition, Euripides was not happy in his domestic relations, but the details on this subject seem to rest on no credible authority. He lived but a short time after he went to Macedon. According to tradition, he was torn in pieces by the hounds of the king. During his short residence there he acquired a great ascendancy over Archelaus, who loaded him with gifts and honors. When the news of his death reached Athens, it threw the whole city into mourning. Sophocles, then 90 years old, was so deeply moved that he changed his garments, and required his actors to lay aside their crowns and appear in mourning on the stage. The Athenians requested that his remains might be sent home for burial; but the request was not granted. They, however, erected a cenotaph to the poet, on the road from the Piræus to Athens, and his statue was afterward set up, with those of Æschylus and Sophocles, in the Dionysiac theatre, by Lycurgus the orator, a contemporary of Demosthenes. The inscription on the cenotaph is supposed to have been written by Thucydides the historian. —Of the numerous works of Euripides only 19 entire pieces have come down to our times. Many fragments of other plays exist, and are published in the editions of his works. Of the extant pieces, the genuineness of one, "Rhesus," has been called in question. Seventeen are tragedies, and two, "Cyclops" and "Alcestis," were intended as afterpieces, like the satyric dramas (of which "Cyclops" is indeed the only remaining specimen) in tetralogies. The earliest of all is "Alcestis," which was brought out in 438; the date of "Orestes" is the latest ascertained, 408; but several of his pieces were brought out after his death by his son Euripides. The best editions are those of Beck (Leipsic, 1778-'88), of Matthiæ (Leipsic, 1813-'37), that of Glasgow (1821), Kirchhoff (Berlin, 1855), Nauck (Leipsic, 1857), Donner (Leipsic, 1859), and Fritze (Berlin, 1866-'8). Paley's edition (3 vols., London, 1857-'60) is the most beautiful. The whole works of Euripides have been translated into English verse by Potter (2 vols. 4to, London, 1781-'2; 2 vols. 8vo, Oxford, 1814), and into prose by Buckley in Bohn's "Classical Library." —On the moral, intellectual, and poetical merits of Euripides, there was in ancient times, as there is in modern, a great diversity of opinion. Among his contemporaries, Socrates thought so highly of him that he made it a point to attend the theatre whenever a play of his was to be performed, and the philosopher delighted in his conversation. Aristophanes, on the other hand, pursued him with the keenest ridicule, denouncing him as the corrupter of tragedy and the teacher of immoral doctrines, and contrasting him unfavorably in these respects with Æschylus and Sophocles. In modern times, A. W. von Schlegel and the critics of his school have adopted the representations of Aristophanes as the basis of a disparaging judgment.

Aristotle, while censuring his faulty management in some respects, yet pronounces him the most tragic of poets. Milton's opinion nearly coincided with that of Aristotle. Euripides is censured as a woman-hater, and it is supposed that his distrust of the female sex grew out of his own domestic experience. He, like Socrates, is charged with a want of belief in the gods of his country. In a literary point of view, the principal charges against him are that he lowered the tone of tragedy and weakened its style; that he degraded heroic characters by representing them in beggary and rags, and by these coarse means attempting to work out pathetic effects; that he too often introduced his plays with long and tedious narrative or genealogical prologues; that his choruses frequently have little to do with the subject of the piece; and finally, that he delighted in the representation of criminal and unnatural passions. These statements, though having a germ of fact, are quite too absolutely made. In his style Euripides is not lofty like Æschylus, nor elaborately elegant like Sophocles. In his plots he is not so simple as Æschylus, nor so carefully balanced as Sophocles. But in the study of human passions, in the analysis of the characters of men and women, in tracing actions to their hidden motives through all the labyrinthine windings of pretence or self-deception, he is undoubtedly their superior. In his plays there is more of philosophy, in spite of the occasional sophistry that deforms them; there are more pithy maxims, sententious expressions of metaphysical and ethical truth, and discussions that really evolve important conclusions bearing upon the conduct of private or public life. If we judge by the busts and statues of Euripides that have come down to us in the collections of ancient art, he was a man of capacious brain, of grave countenance, and studious habits.

EURIPUS, the narrowest part of the channel separating the island of Eubœa, in the Grecian archipelago, from the coast of Bœotia. Its width, opposite the town of Chalcis, is 200 ft., and its average depth from 7 to 8 ft. In the channel is a rocky islet, on which is a small square castle, partly of Venetian and partly of Turkish construction, connected by bridges with both shores. It is under this double bridge, which was built originally in the 21st year of the Peloponnesian war, that the extraordinary changes of current, noted by both ancient and modern writers, take place. These irregularities of the tide are probably caused by the windings of the gulf N. and S. of the strait. In the middle ages Euripus was corrupted into Egripo, which afterward became Egripo-ponte, and finally Negroponte, its more modern appellation. With other important points in Greece it has lately resumed its ancient name.

EUROPA, in mythology, according to the Iliad, a daughter of Phoenix, mother of Minos and Rhadamanthus by Zeus, who, disguised as a white bull, bore her upon his back across the

sea from Phœnicia to Crete. Hegesippus says there were three Europas: one a daughter of Oceanus, another a Phœnician princess, the daughter of Agenor, and the third a Thracian, in search of whom Cadmus left Asia. He derives the name of Europe from the last, Hippias and Andron from the first, and Herodotus from the second.

EUROPE, one of the five principal divisions of the globe, the smallest except Australia, but the most important in the history of civilization. Geographically considered, it is merely a N. W. peninsula of the Asiatic continent, but from the earliest times it has been distinguished as a separate division. The Greeks first applied the name to that portion of the continent nearest to them, and traced it to the myth of Europa. But there have been many other theories, none of which has remained uncontested. Ancient writers derive the name from Eurus, south wind, or from *εὐρώς* and *ἀντα* (a Scythic word, quoted by the Greeks), the broad land, or from *εὐρύς* and *ὄψις*, the broad-looking (land). Modern scholars have sought for the origin of the name in the Semitic languages. Thus Bochart derives it from the Hebrew word *ereb* (west), while others hold that it is a corrupt form of the words *havra appa* (white-faced). If the name be Semitic, it must have been introduced by the Phœnicians, who were early familiar with almost all the shores of Europe. Their neighbors, the Hebrews, however, had no general name for the countries N. of the Mediterranean, though they were well known to them. The name of Europe does not appear in Homer's catalogue of countries, though it occurs, and so far as we know for the first time, in the Homeric hymn to Apollo. It is here applied to a region especially distinguished from the Peloponnesus and the Greek islands, but to exactly what portion of the then known world it is impossible to determine. Greece, the islands of the Ægean and Ionian seas, Sicily, Thrace, and a part of southern Italy, seem to have been all the territories now included under the designation of which the contemporaries of Homer had any definite knowledge. In the time of the historian Hecæteus (about 500 B. C.) some acquaintance had been made with the general features of Spain, southern Gaul, the region near the source of the Rhine, the borders of the lower Danube, and the shores of the Euxine and of the Palus Mæotis (sea of Azov); Italy, all the Mediterranean islands, and Thrace were now perfectly known. Herodotus, though in his day exploration had been carried much further to the north, placed the northern boundary of Europe (which he like his predecessors believed to be formed by the great river Oceanus) at a considerable distance south of the coast of the Baltic; but in his time the eastern and southeastern boundary afterward accepted as the limit of Europe by all the ancient nations, and formed by the Tanais river (Don), the Palus Mæotis, and the Cimmerian Bosphorus (strait of Yenikale), was

already well defined; the knowledge of northern and central Gaul had been largely increased, and all the south-central region was comparatively well known ground. Even in Strabo's time, when the North and Baltic seas were considered the extreme northern boundaries, the central and north-central portions of the continent were still but little explored; the present Russian possessions were almost entirely unknown; and though the great provinces conquered by Rome had now been thoroughly surveyed, it was not till the northern campaigns of Drusus Nero (B. C. 12-9) and of Germanicus (A. D. 14-16) that any really accurate knowledge of the northern Germanic regions appears to have been gained. About this period, too, the existence of the Scandinavian peninsula, northern Russia, and the Arctic ocean seems to have become known. From this time exploration and the knowledge of European geography made rapid progress; but it was not perfected until the political supremacy had passed from the Roman to the Germanic races.—Though much smaller in size than either Asia, Africa, or America, Europe has for many centuries exerted a greater influence upon the destiny of other portions of the globe than all the other divisions. For nearly 1,000 years subsequent to the downfall of the Roman empire, it is true, it slowly and laboriously struggled through barbarism at a time when the Mongolian race in eastern Asia had already attained a more perfect state of society and culture. It is only within the last four centuries that European civilization has matured so far as to be able to wield a controlling influence over distant regions and to stamp its seal upon their political state.—According to Ritter, Europe, with all islands belonging to it, has a superficies of 3,700,000 sq. m., and 20,780 m. of coast line, including 790 on the Caspian sea. Behm and Wagner (*Bevölkerung der Erde*, 1872) estimate the total area at 3,787,000 sq. m.; while the *Almanach de Gotha* and several other eminent statistical authorities agree in stating it at about 3,627,000 sq. m. Regarding the length of the coast line there is a much greater difference in the estimates, but Ritter's is probably nearly correct. The extreme points of the European continent are:

North:	Cape North,	lat. 71° 10' N.,	lon. 25° 46' E.
South:	Cape Taria,	" 26° 00' N.,	" 5° 38' W.
West:	Cape Roca,	" 38° 46' N.,	" 9° 31' W.
East:	Sea of Kara,	" 63° 00' N.,	" 66° 00' E.

The length of Europe from Cape St. Vincent in the southwest to the sea of Kara in the northeast is about 3,450 m.; the width from Cape North to Cape Matapan (the southernmost point of the Greek peninsula), 2,420 m. Europe is bounded N. by the Arctic ocean, E. by the Ural mountains and river and the Caspian sea, S. by the ridge of the Caucasus mountains, the Black sea, and the Mediterranean, and W. by the Atlantic ocean. The boundary line between Europe and Asia is somewhat un-

determined, but that which ascends the Ural river from its mouth at the Caspian sea to the Ural mountain range, and follows the crest of that range to the sea of Kara, is usually adopted. The islands of Nova Zembla are set down by Humboldt as properly belonging to Asia, since by their vertical configuration they appear as a continuation of the Ural range, which he included in Asia. Erman, on the contrary, shows their connection with the Scandinavian mountain system, and this is also the view taken by most English geographers. The continent proper has the shape of a rectangular triangle, the hypothenuse of which extends from the bay of Biscay to the sea of Kara, while the right angle rests on the Caspian sea. The area of this main body of the continent is about 2,650,000 sq. m., that of the peninsular projections about 860,000, and that of the islands nearly 200,000. Altogether Europe contains about $\frac{7}{10}$ of the total area of the dry land of the globe. The proportion of the total area of the peninsular projections to the main body of the continent is as 1 to 3, a larger ratio than is found in any other division of the globe. A curved line drawn from a point in the Ural mountains, lat. 60° or 61° N., to the W. coast of Norway, lat. 69°, passing through Lake Onega and a little N. of the gulf of Bothnia, marks the general limit of cultivation. It cuts off an area of about 550,000 sq. m., or more than one seventh of the entire surface. Europe is surrounded by water on three sides. On the north the Arctic ocean, penetrating 400 m. into the continent, forms the White sea, which has an area of upward of 40,000 sq. m. Its coast, situated for the greatest part within the temperate zone, has become a seat of culture notwithstanding its high latitude. On the west the Atlantic ocean, narrowing between the British islands, the Scandinavian peninsula, and the continent, assumes the form of an inland sea (North sea, or German ocean, area upward of 200,000 sq. m.), which is connected by the Skager Rack and Cattegat with the Baltic sea. The Baltic, comparatively a shallow sea, and less salt than the ocean, is almost entirely landlocked. By its numerous affluents, however, it has obtained a commercial and even a political importance in the history of the Teutonic race almost equal to that of the Black sea in early Greek history. Its area, exclusive of islands, is over 150,000 sq. m. The configuration of the southern coast of Europe is determined by the Mediterranean sea (including the Adriatic and archipelago), a sheet of water over 2,300 m. in length, covering an area of over 1,000,000 sq. m. By its position it forms the connecting link between Europe, Asia, and Africa, and for more than 20 centuries the history of the Caucasian race was principally developed upon its coast. The Black sea, connected with the Mediterranean by a narrow channel, is 700 m. long, 400 m. broad, and has a superficies of 180,000 sq. m. exclusive of the sea of Azov. In consequence of the deep in-

dentations of the sea, the western half of Europe contains no great inland country shut up from direct communication with the ocean. The distance from the bay of Biscay to the gulf of Lyons is only about 240 m.; from the English channel to the same gulf, 445 m.; from the Pomeranian shore of the Baltic to the gulf of Trieste, 585 m.; from the gulf of Dantzic to the Black sea, 740 m.; from the gulf of Finland to the sea of Azov, 950 m.; from the White sea to the sea of Azov, 1,160 m.; and from the sea of Kara to the Caspian sea, 1,575 m. Twelve large peninsulas are formed by indentations of the sea, five of them on the north: Kanin, Kola, the Scandinavian peninsula, the Cimbric, and North Holland; two on the west: Normandy and Brittany; one on the southwest: the Iberian; and four on the south: Italy, Istria, Greece, and the Crimea. The first two of the five northern peninsulas stretch toward the Arctic ocean, and are consequently almost uninhabitable. The largest of the five (the Scandinavian) has a southern direction. Thus only a small portion of the coast configuration is lost to culture and commerce. The islands, too, with the exception of Iceland, cluster so closely around the continent that, in considering the natural facilities which Europe offers to commercial intercourse, their coast line might be added to that of the continent. The principal of them are: the main island of Great Britain, Ireland, Iceland, Seeland, Corsica, Sardinia, and Candia. The following may also be mentioned: Nova Zembla and Vaigatch, in the Arctic ocean; the Loffiden, on the coast of Norway; the Aland archipelago, Öland, Gothland, Oesel, in the Baltic; Fünen, between the two Belts; the Azores, in the Atlantic; Majorca, Minorca, Elba, the Lipari islands, Malta, the Dalmatian archipelago, the Ionian islands, the Sporades and Cyclades, in the Mediterranean sea and its branches.—The same direction from S. W. to N. E. which prevails in the coast configuration is perceptible in the position of the mountains and their different strata. All the peninsulas, those stretching to the northward excepted, are mountainous, as are the islands, while the plains cover the largest portion of the main body of the continent. The proportion of the plains to the mountainous regions in all Europe is as 5 to 2; but in that portion of Europe which has been preëminently the seat of civilization and the theatre of history, the mountains prevail over the plains as 3 to 1. A diagonal line of mountain ranges, extending from S. E. to N. W. (Caucasus, Carpathians, and the mountains of central Germany), forms the dividing line between the mountainous and the level portions of Europe. The level region extending from the shores of the North sea to the Ural, and from the coast of the Netherlands in an irregular southeasterly direction to the Black sea, appears as a western continuation of the steppes of Siberia and Turan, intersected by the isolated Ural range. While on the shores of

the North sea its width is less than 100 m., in the extreme east it is 1,400 m. wide. Its entire length is near 2,300 m., its area about 2,000,000 sq. m. Proceeding from the heaths of West Brabant in an easterly direction, even beyond the Ural passes to the steppes on the western slope of the Altai mountains, 80 degrees of longitude, no elevation of over 1,200 or 1,300 ft. above the level of the sea is met with. The western or European portion of this plain appears to have formed, after the commencement of the tertiary period of geology, the bed of the sea. It includes the basins of the Baltic and White seas. A part of it is traversed by rivers flowing northward from the Alps, the mountains of central Germany, and the Carpathians. To the eastward the watershed between the Baltic and the Black and Caspian seas is only a few hundred feet in elevation; commencing at a spur of the Carpathians near the source of the Dniester, it runs through the Russian governments of Volhynia, Grodno, Minsk, Mohilev, Smolensk, Pskov, Tver, Novgorod, and Vologda, to the Ural range. Though interspersed with marshes, bogs, and heaths, this immense plain is susceptible of high culture, but nowhere is the soil so fertile as to produce crops without laborious diligence. Connected with this large plain are two lesser ones, in France and in Hungary.—The mountain system of southern and western Europe is grouped around the central mass of the Alps, which forms the summit and the principal watershed of the continent. The Alps, covering an area of nearly 100,000 sq. m., slope down on four sides toward France, Germany, Hungary, and Italy. The highest elevation of this system and of all Europe is Mont Blanc (15,732 ft., according to Bruguère). The lowest limit of perpetual snow in the Alps is 8,760 ft., between lat. 45° and 46° N. Connected with the Alpine system are the mountain systems of the three southern peninsulas, viz., the Pyrenean system, the Apennines, and the Balkan, and also the group of the Carpathian and Sudetic mountains. The Pyrenees stretch from E. to W. for 240 m., but, including the Cantabrian mountains, their length is 500 m. Their S. side, toward Spain, is rugged and precipitous, while on the north they descend gradually by a series of parallel ridges into France. They send four principal branches through the Iberian peninsula, the whole system covering a superficial area of about 200,000 sq. m. The culminating point of the system, in its widest acceptance, is the Cerro de Mulhacen in the Sierra Nevada (11,654 ft.). The Apennines, stretching from the Alps through the entire length of Italy to the strait of Messina, cover an area of 60,000 sq. m. Their highest summit is Monte Corno (9,542 ft.). The Carpathian and Sudetic mountains, with the Erzgebirge and the Bohemian Forest, form one chain extending 1,200 m. in length, from the Danube in Hungary to the same river in Bavaria. Their highest elevations, from 6,000 to 9,000 ft., are in Transyl-

vania and Hungary, where they surpass the lower limit of perpetual snow. The Balkan, a direct continuation of the Dinaric Alps, sweeps in an irregular curve from the Adriatic to the Black sea. Its principal part is the Hæmus of the ancients. Its general elevation is about 4,000 ft.; a few of its summits rise about 4,000 ft. higher. Thence one range, including the ancient Pindus, diverges to the south, dividing Albania from Roumelia, and connecting with the mountains of Greece, the loftiest summits of which attain an elevation of upward of 8,000 ft. Another, the Rhodope of the ancients, now called Despoto Dagh, diverges further E. in a S. E. direction, and, traversing western Thrace, reaches the archipelago. The Rilo Dagh, near its starting point, is 9,838 ft. high. Between the two are various branches, one of which includes Mt. Olympus, 9,754 ft. Between the Alpine system proper, the Pyrenees, and the Atlantic (in France), there are three separate mountain ranges, viz., the Cévennes and mountains of Auvergne, the Jura, and the Vosges. The first divides the low country on the Mediterranean and the basin of the Rhône from the plains extending W. to the Atlantic; its general elevation is from 3,000 to 5,000 ft., though some peaks (Mont Dore, Cantal, and Mont Mezin) rise to a height of about 6,000 ft. The Jura, of nearly the same elevation, extends along the frontier of France and Switzerland. Further N. the Vosges divide the basin of the Rhine from that of the Moselle, their loftiest summits reaching an altitude of about 4,700 ft. There are several plains, independent and differing in their principal features from the great northern plain, enclosed by the Alpine system, namely, the basins of the Po, the Rhône, and the upper Rhine. Besides the above mentioned ranges, all more or less immediately connected with the central system of the Alps, Europe contains in its islands and peninsulas five distinct mountain systems. They are the Sardo-Corsican, the Tauric, the British-Hibernian, the Scandinavian, and the Sar-matian. The Sardo-Corsican, as its designation implies, is the range of mountains stretching from N. to S. through the islands of Corsica and Sardinia; its highest summit, Monte Rotondo in Corsica, has an elevation of 9,054 ft. The Tauric system is confined to the southern portion of the Crimea, its greatest elevation being 4,740 ft. The British-Hibernian system, in Great Britain and Ireland, is comparatively insignificant, rising in its highest peaks (in Scotland) but little over 4,000 ft. The Scandinavian Alps (Kjölen and Dovrefield) extend 1,000 m. from N. to S. through the entire length of the Scandinavian peninsula, at a general elevation of from 3,000 to 6,000 ft. The highest summits are Ymes Field, 8,540 ft., Skagtöls Tind, 8,061, and the Sneehætten, 7,562 ft. In the N. portion the lower limit of perpetual snow is at 3,500 ft. above the level of the sea. The Sar-matian system consists only of a few scattered hill chains in Russia,

Poland, and the N. E. part of Prussia; its greatest elevation, in the plateau of Valdai, is only 1,150 ft. The Ural range, which forms the northern portion of the E. boundary line of Europe, extends from N. to S. through 18 degrees of latitude, with a general elevation of about 2,000 ft., several summits rising to a height of more than 5,000 ft. Toward the south it diverges into smaller ridges that extend to the Caspian sea, the sea of Aral, and the steppes of the Kirghiz. A volcanic belt extends through the southernmost portion of Europe from central Asia and Asia Minor through the archipelago, Greece, Naples, Sicily, Spain, and Portugal, to the Azores. Along this line destructive earthquakes are of frequent occurrence. Besides many extinct craters, there are two active volcanoes, Etna in Sicily and Vesuvius near Naples. In the north, Iceland constitutes a distinct volcanic region. Its principal volcano is Mt. Hecla, some eruptions of which have lasted for six years. The S. W. portion of the island contains the famous geysers, or intermittent springs of steam and boiling water. There are two other volcanoes, one on the island of Jan Mayen, between Iceland and Spitzbergen, the other on the northern island of Nova Zembla. —The river systems of Europe are less extensive than those of either Asia or America. The principal watershed, running S. W. and N. E., from the strait of Gibraltar to the sea of Kara, divides the continent into a S. E. and a N. W. slope, the former containing about four sevenths and the latter three sevenths of the total area. On the S. E. slope the basin of the Caspian sea comprises over 500,000 sq. m.; that of the Black sea and the sea of Azov about 950,000 sq. m.; and the basin of the Mediterranean sea, 575,000 sq. m. On the N. W. slope the Atlantic basin and the basin of the Baltic comprise about 450,000 sq. m. each, the basin of the North sea 400,000, and that of the Arctic ocean nearly 200,000. The following are some of the more important rivers flowing into the different seas: 1, Caspian sea: Ural and Volga; 2, sea of Azov: Don; 3, Black sea: Dnieper, Dniester, Danube; 4, Mediterranean: Maritza, Isonzo, Adige, Po, Tiber, Arno, Var, Rhône, Ebro; 5, Atlantic: Minho, Douro, Tagus, Guadiana, Guadalquivir; 6, bay of Biscay: Garonne, Loire; 7, British channel: Seine, Somme; 8, North sea: Scheldt, Rhine, Ems, Weser, Elbe, Eider; 9, Cattegat: Glommen; 10, Baltic sea: Ulea, Neva, Düna, Niemen, Vistula, Oder, Dal Elf, Angermann Elf, Umea Elf, Pitea Elf, Lulea Elf, Tornea Elf; 11, Arctic ocean: Onega, Dwina, Mezen, Petchora. Besides these, there are the rivers of the British islands, the chief of which are the Thames, Severn, Humber, and Mersey, in England; the Tweed, Clyde, and Forth, in Scotland; the Shannon, Blackwater, Liffey, and Boyne, in Ireland. The largest river of Europe is the Volga, with a course of 2,300 m. and a basin of 500,000 sq. m.; next comes the Danube,

with a length of 1,820 m. and a basin of 300,000 sq. m. Artificial watercourses connect the Caspian sea, the Baltic, and the Arctic ocean, by the Volga, Neva, Düna, and Dwina rivers; the Black and the North sea by the Danube and Rhine; the Mediterranean and the Atlantic ocean, the British channel and the North sea, by numerous canals between the Rhône, Garonne, Loire, Seine, Scheldt, and Rhine. The middle course of most of the large rivers is well adapted to navigation by steam and other vessels, but their usefulness for the purposes of commerce is restricted by obstructions at their mouths. Such is especially the case with the Volga, Don, Danube, and Rhine.—The lakes of Europe are small, and scarcely any of them are important to commerce. The following are among the largest: Ladoga (between 6,000 and 7,000 sq. m.), Onega, Saima, and Enare, in Russia; Wener (about 2,000), Wetter, and Mælar, in Sweden; Lake Balaton (450), in Hungary; the lakes of Geneva and Constance in Switzerland; and Garda and Lago Maggiore, in Italy. Four fifths of the lakes in Europe are situated in the region around the Baltic sea. (The geology of Europe is treated under the special heads of the different countries and mountain ranges.)—The whole of Europe, with the exception of a small northernmost portion of the Scandinavian peninsula and Russia, being situated within the temperate zone, enjoys an equable and temperate climate. The disadvantages arising from the proximity of the Arctic ocean and the climatic influences of northern Asia are more than overborne by many advantages which no other division of the globe enjoys in an equal degree. The prevailing winds are western, and hence before reaching Europe have been in contact with an expanse of water, the surface of which has, even in January and in lat. 45–50° N., rarely a lower temperature than 50° F. In the second place, Europe is influenced by a broad tropical zone, including Africa and Arabia, whose dry soil serves to warm the air carried to Europe by southern winds. On the other hand, the influence of the Arctic ocean upon the climate of the continent is neutralized by the Gulf stream. The combination of all these advantages explains the fact that the mean temperature of Europe is higher than that of any other division of the globe in corresponding latitudes, the isothermal lines of Asia and America bending in Europe to the northward by some 10 degrees of latitude. Thus in lat. 36° N. the mean temperature of the year is 66° F., and in lat. 71° N. (Cape North) it is 32° F., not lower than in lat. 56° N. on the E. coast of Asia and America. Owing to the causes before mentioned, the mean temperature of Europe is higher and the extremes are less in the same latitudes in the western than in the eastern part. The isothermal line of 50° F. (mean annual temperature) runs from London to Cracow and Odessa, that is to say, from lat. 51° 30' to 46° 22' N., thus declining

5° of latitude to the south in a course of 31° 5' of longitude. A mean annual temperature of 68° is only met with on the southern coast of Portugal. But while the mean temperature diminishes advancing eastward, the extremes of the heat of summer and the cold of winter increase. Thus London has the same mean temperature as Vienna, which lies more than 3° further S., but it has the summer of St. Petersburg and the winter of Milan. The transitions from winter to summer and from summer to winter are less abrupt in the largest portion of Europe than they are in America. Almost everywhere the seasons succeed each other with great regularity. The extreme north only, where the winter lasts for eight months, and the extreme south, form exceptions. The fall of rain is more equally distributed N. of the Alpine system than S. of it. It has been calculated that the entire quantity of rain falling in the N. part of Europe is less by one third than in the S., but the snow of the north covers the deficiency of rain. The western winds, being laden with the moisture which they have received in passing the Atlantic, generally bring rain, while the eastern winds are dry and chilly. From the same cause the average quantity of rain is largest in Great Britain, and decreases in advancing E. and S. E. Thunderstorms occur in the N. part of Europe almost exclusively during the summer, in the S. part at all seasons of the year.—The vegetation of Europe, dependent upon and corresponding to its climate, has not the extremes of luxuriance or sterility belonging to other great continents. Culture has diversified it, and has domesticated many plants, natives of other countries. Thus the vine, olive, and mulberry have been introduced from Syria, the cotton plant from India, maize from North America, the potato from South America, the walnut and peach from Persia, the apricot from Armenia, the sugar cane and orange from China; while many of the indigenous plants, especially vegetables (as lettuce, cabbage, turnips), have been improved by culture to such a degree that their relationship with their wild types is scarcely evident. Europe may be divided into three vegetable zones, viz.: 1. The sub-arctic zone, characterized by the prevalence of the pine and birch and of cryptogamous plants. It produces little grain except barley, and no fruit. This zone comprises Iceland, the Faroe islands, the Scandinavian peninsula N. of lat. 64°, and Russia N. of lat. 62°. 2. The central zone, subdivided into the zone of the beech and oak, and that of the chestnut and vine. The former includes Great Britain and Ireland, the Scandinavian peninsula S. of lat. 64° N., and the German and Sarmatian plain between lat. 62° and 48°. The latter comprises the valleys and plains between the mountain ranges of central Europe and the Sarmatian plain. In the former, rye and wheat are the principal grains; in the latter, wheat and maize. 3. The southern zone, or

the region of perpetual verdure, and of the olive, comprising the three southern peninsulas and the southern coast country of France, distinguished by a great variety and luxuriance of sub-tropical vegetation. The sugar cane, cotton plant, orange, citron, fig, pomegranate, and date grow in the southernmost belt of this region. The zones in which these fruits and plants grow follow the lines of equal summer heat, and hence run from S. W. to N. E., since the extremes of summer heat and winter cold increase advancing eastward, though the mean annual temperature decreases. Thus the cotton plant is cultivated on a small scale in the southernmost portion of Spain, from lat. 36° to 37°, more largely in Sicily and in the S. E. angle of Italy, in the Balkan peninsula as high as lat. 41° 30', and at Astrakhan in lat. 46°. The olive, which does not succeed on the W. coast of France in lat. 43°, grows as far as lat. 44–45° in the S. E. provinces of France and in Italy. The fig and pomegranate, which accompany the olive in the west, are found in the Crimea as far N. as lat. 45°. The climate proper for the culture of maize terminates on the W. coast of France at lat. 45° 30', on the Rhine at 49°, and on the Elbe at 50–51°. Rice has nearly the same geographical range. The culture of the vine extends as far N. as lat. 47° 30' on the Atlantic coast, 50° 30' on the banks of the Rhine, 52° on the Oder river. In Russia it grows as far N. as lat. 52°, but it is not cultivated beyond 50°. Altogether the region adapted to the cultivation of the vine comprises about three sevenths of Europe, that adapted to the culture of wheat four sevenths. The N. limit of the latter is lat. 57–58° N., though it is raised in a few favored spots in Finland as far N. as lat. 60° and 61°. The hardier kinds of grain, rye, barley, and oats, are cultivated on the W. side of Norway as far as lat. 69° 55' N., but on the E. side of the Scandinavian mountains they scarcely ripen at 67–68°, and still further E. in Russia they cannot be cultivated beyond lat. 60–62°. Peaches and apricots succeed in Russia as far N. as lat. 50°, melons at lat. 52°; and plums and cherries, growing wild as far as lat. 55°, are carried beyond that limit by cultivation. Tobacco is extensively cultivated over the greater part of Europe, from Sicily to Sweden, as are flax and hemp, though they thrive best between lat. 45° and 60°.—Europe contains the various minerals, though in unequal proportions. It is abundantly supplied with iron, copper, lead, coal, and salt, but produces comparatively small quantities of gold and silver. Gold, though widely diffused, is only found in a few places (Carpathians, Ural mountains, and Scandinavian Alps) in sufficient quantities to repay the expense of working it. Silver is mined in the Hartz, the Carpathians, Ural mountains, Scandinavian Alps, and Sardinia. The richest iron mines are in Sweden, which produces the best quality, in Great Britain, which has the largest quantity, in Styria, Carinthia, Bavaria, the Py-

renees, the Carpathians, and the Hartz mountains. Copper is less abundant than iron; the richest mines of this metal are to be found in Hungary, the Saxon and Bohemian mountains, in England, the Ural mountains, and the Scandinavian Alps. Lead is wrought in most of the large mountain ranges, tin only in a few places (Cornwall and the Hartz). Mercury is likewise confined to a few spots, as the mines of Idria in Carniola, Zweibrücken in the Palatinate, and the Spanish province of La Mancha. The richest coal fields exist in the N. and W. parts of England, on both sides of the middle region of Scotland, in Ireland, Belgium, France, Germany, Hungary, Catalonia in Spain, and Sardinia. Salt is either obtained by the evaporation of brine from salt springs, or from depositories of mineral salt, of which the most extensive are found within the Austro-Hungarian empire at Wieliczka, in Marmaros, and in Salzburg. Salt springs are numerous along the sides of all mountains belonging to the primitive formation. Large quantities of salt are also collected from the salt lakes of the Crimea. Zinc is wrought in England and Germany, and cobalt in Saxony and Sweden. Besides these metals, antimony, bismuth, manganese, sulphur, alum, &c., are obtained in larger or smaller quantities in the different mountain chains.—The animal kingdom of Europe is far less varied than the flora. The diversities of the three zoölogical regions are inconsiderable, and the only real contrast is between the arctic animals of the extreme north, as the reindeer, white bear, &c., and the beasts of prey of the extreme south, the lynx, wild cat, &c. The original features of the fauna of Europe have been greatly modified by culture. Several species of wild animals have disappeared entirely in many countries, as the wolf and bear in Great Britain and in some parts of the continent, while others are becoming scarcer from year to year. Thus the aurochs and the elk in some provinces of Russia, the porcupine in the extreme south, the monkey near Gibraltar, the chamois and ibex in the higher mountain ranges. But if Europe is poor in wild beasts, it is rich in domestic animals. In the northernmost region, as far S. as lat. 63° in Russia, the domesticated reindeer abounds; central Europe has immense numbers of horses, horned cattle, sheep, goats, and hogs; and southern Europe possesses, besides these, mules, camels (in South Russia), and buffaloes. Of small birds Europe has several hundred species, but many of them are only birds of passage. Among those kinds of birds peculiar to certain regions are the flamingo, spoonbill, pelican, and vulture in the south, gray eagle in the north, eider duck, swan, and red grouse in the north and north-east, bee-eater in the southeast, white owl in the extreme north, &c. Various species of turtles excepted, Europe has no large amphibia. Fish are more abundant on the N. than on the S. coast; herring and codfish are found only in the north, sturgeon in the Rus-

sian rivers and seas, anchovies and pilchards on the S. W. coast, tunny fish in the Mediterranean. Of insects, several kinds of tarantula and scorpions are peculiar to Europe. The silkworm is raised principally in the southern countries, and the honey bee in all the temperate portions of the continent. The annelids of Europe include the medicinal leech (in Sweden, Germany, Hungary, and Poland). Europe is abundantly supplied with edible mollusks, but they are found in greater abundance and better quality in the Mediterranean sea than on the N. coast. Radiated animals, zoöphytes, &c., also abound on the S. coasts, where some of them (the actinias) are used as food, and where the coral fisheries employ many persons. Generally the S. part of Europe possesses a greater variety of animals and species than the N., while the latter has them in greater numbers.—The inhabitants of Europe are the descendants of many different tribes, though the great majority belong to the Indo-European branch of the human family, and would seem to have sprung originally from a common stock. Without referring to the prehistoric migrations of the various races which are more or less distinctly traceable through philological and archaeological investigation, and which are treated in other articles, it is sufficient to indicate in this place the positions occupied by the different peoples at the period of the earliest written records; as it is from nations then already settled in the continent that the present population is almost entirely derived. At the dawn of history, then, the W. and S. W. portions of Europe appear to have been in possession of the Celts and the Iberians. In the east and north-east the Ugrian (Mongolian) races (part of the Scythians of the ancients), of whom the Lapps, Finns, Samoyeds, and Magyars are the present remains, seem to have been the original inhabitants. At an early period the Slavs settled in the countries N. of the Black sea, and pressing N. E. gradually dispossessed the Ugrians of their country. Between the Ugrian and Slavic races of the east and the Celts of the west, the Germanic races are found at the earliest period of traditionary history pressing N. to conquer Scandinavia and S. against France and Italy. The southeast of Europe was probably settled from Asia and Africa; history finds in Greece and Italy two races who afterward became known as the Hellenic and Roman. The former was the first to develop in Europe a high state of culture, which, having been received by the conquering Roman race, was carried over all the countries around the Mediterranean. Having exhausted their power, the Roman conquerors were in their turn overthrown by the hardy, vigorous, and barbarous northern nations, who, after having embraced Christianity, in the course of many centuries developed a new and different civilization. The Heruli, Ostrogoths, Longobards, and other Teutonic tribes, penetrated into and settled in Italy; Suevi, Visigoths, and Vandals in Spain; Franks

and Burgundians in Gaul (France); Angles, Saxons, Jutes, and Frisians in Britain. In Italy, Spain, and France, the conquerors were mostly assimilated to the nations whom they had found there, and by their admixture with them the present so-called Latin or Romanic race was produced. In Britain, the invaders drove the original inhabitants into Wales, Cornwall, and Cumberland, but were in their turn invaded by Normans and French in the 11th century; and the admixture of all these different elements, Celtic, Anglo-Saxon, and Norman, gradually produced the present English race. In Spain, the Teutonic tribes were overrun by Arabs in the 8th century, and did not recover possession of the whole country for nearly eight centuries. In the southeast the Hellenic race became during the middle ages largely mixed with the Slavic, while around the lower course of the Danube an intermixture of the ancient Dacians with a Roman colony produced the present Rouman or Wallach race. Toward the end of the 9th century an Ugric race settled in the ancient Pannonia, where they remain to the present day under the names of Magyars and Szeklers in Hungary and Transylvania. Of the Tartars who under Genghis Khan entered Europe in the 13th century, and kept possession of a large portion of Russia till the end of the 15th century, some descendants still remain in the south of that empire. The Osmanli, another branch of the Mongolian race, invaded Europe in the 14th century, and have ever since kept possession of the S. E. corner of the continent. By mingling freely with western nations they have lost many characteristic features of the Mongolian stock. —The population of Europe, which can now be estimated with accuracy, owing to the fact that official censuses are taken in all countries of the continent, amounted in 1872, according to the best authorities, to about 301,000,000, or about 80 to the square mile. Its distribution between the E. and W. portions is very unequal, the average population on a square mile being about 34 in Russia, which occupies the eastern half of the continent, and about 125 in the west. With the exception of the three free cities in Germany, the canton of Geneva, and Malta, the greatest density of population prevails in Belgium (447); then follow in order the Netherlands (279), Great Britain and Ireland (263), Italy (234), Germany (197), France (177), Switzerland (167), Austria (149), Denmark (121), Portugal (117), Spain (85), Turkey (80), Greece (75), Russia (34), Sweden (27), and Norway (15). The average natural increase per annum of the population varies from 0·5 to 1·43 per cent. It is 1·43 per cent. in Great Britain, 1·16 in Prussia, 0·6 in all Germany, 0·59 in France. Ireland is the only country in which there has been of late a steady decrease of population. There were in Europe in 1872, in all, 67 cities with more than 100,000 inhabitants to each. The following table exhibits in round figures the

comparative numbers of different races among the present population of Europe :

I. INDO-EUROPEAN OR ARYAN FAMILY.	
1. Græco-Latin races.	
<i>a.</i> Greeks.....	3,000,000
<i>b.</i> Latin nations.	
<i>a.</i> Italians.....	27,000,000
<i>β.</i> Rhetians (in Switzerland, Tyrol, &c.).....	100,000
<i>γ.</i> French (including the Provencals).....	37,000,000
<i>δ.</i> Spaniards and Portuguese.....	19,000,000
<i>e.</i> Roumans.....	8,000,000
	<hr/> 94,100,000
2. Celtic race.	
<i>a.</i> Celts in the British isles.....	6,500,000
<i>b.</i> Celts in Brittany.....	1,000,000
	<hr/> 7,500,000
3. Germanic or Teutonic races.	
<i>a.</i> Germans, Dutch, and Flemings.....	56,000,000
<i>b.</i> Scandinavians (Danes, Norwegians, Swedes, Icelanders).....	8,000,000
<i>c.</i> English (Anglo-Saxons).....	23,500,000
	<hr/> 87,500,000
4. Slavic races.	
<i>a.</i> Russians (including Ruthenians, &c.).....	57,000,000
<i>b.</i> Poles.....	11,000,000
<i>c.</i> Wends.....	150,000
<i>d.</i> Czechs and Slovaks.....	7,000,000
<i>e.</i> Illyro-Serbs (Serbs, Croats, Slavons, Dalmatians, Slovenes, Bosnians, Herzegovinians, Montenegrins).....	7,500,000
<i>f.</i> Bulgarians.....	5,000,000
	<hr/> 87,650,000
5. Letts and Lithuanians.....	3,000,000
6. Caucasian races.	
<i>a.</i> Georgians, Armenians, &c.....	1,500,000
<i>b.</i> Caucasian tribes.....	1,000,000
	<hr/> 2,500,000
7. Albanians.....	1,500,000
8. Basques.....	800,000
9. Gypsies and scattered inhabitants of Indian race.....	250,000
Indo-European family.....	<hr/> 284,800,000
II. SEMITIC FAMILY.	
1. Jews.....	5,000,000
2. Arabs (Moors and Maltese).....	100,000
Semitic family.....	<hr/> 5,100,000
III. MONGOLIAN OR TURANIAN FAMILY.	
1. Tehudic branch of the Finnic race.	
<i>a.</i> Finns proper.....	1,500,000
<i>b.</i> Estonians.....	500,000
<i>c.</i> Lapps, Tchuds.....	50,000
	<hr/> 2,050,000
2. Magyars (including Szeklers).....	5,500,000
3. Turks.	
<i>a.</i> Osmanli.....	1,750,000
<i>b.</i> Mixed Turkish and Tartar peoples.....	1,000,000
	<hr/> 2,750,000
4. Minor tribes (Samoyeds, Votiaks, Mordvins, &c.).....	1,500,000
Mongolian family.....	<hr/> 11,800,000
Grand total.....	<hr/> 301,700,000

—For the classification of the languages, which almost closely correspond to the races and peoples enumerated in the table, see ARYAN LANGUAGES, ETHNOLOGY, SLAVIC RACE AND LANGUAGES, and TURANIAN RACE AND LANGUAGES. —With the exception of China proper, the physical culture of no other part of the world is so much developed as that of Europe. Of the total area, 20 or 23 per cent. is non-productive, being either lakes, rivers, swamps, rocks, or occupied by buildings, or, like the extreme northern portion, unfit for human habi-

tation; 36 per cent. is devoted to agriculture or cattle raising; and over 40 per cent. is in forests, of which Russia alone has more than 1,000,000 sq. m. The best cultivated countries are Great Britain, Germany, and France. The introduction of scientific methods of agriculture into these countries has tended steadily to increase the productive capacities of the soil. The average crop of grain to the acre is considerably larger than in the United States. The last trustworthy estimate of the number and value of domestic animals in Europe, as computed by Reden about 1860, gives the statistics as follows: Horses 27,000,000, valued at \$775,470,000; horned cattle 80,000,000, value \$864,720,000; sheep 191,000,000, value \$687,600,000; asses 1,800,000, value \$12,600,000; goats 16,800,000, value \$36,450,000; hogs 37,500,000, value \$108,240,000; mules 800,000, value \$17,160,000; aggregate value of domestic animals, \$2,502,210,000. The average yearly mineral production was estimated as follows by Kolb in 1871: gold, 53,000 lbs.; silver, 470,000 lbs.; iron, 177,000,000 cwt.; copper, 916,000 cwt.; lead, 4,510,000 cwt.; coal and brown coal, 3,450,000,000 cwt.; salt, 100,000,000 cwt. The industrial production is largest in Great Britain, Belgium, France, and Germany. The total annual value of European commerce was estimated by Kolb in 1871 at \$7,960,000,000; but he called attention to the fact that as all goods are counted in one country as imports and in another as exports, and many in a third also in the transit trade, the real value must be considerably less than half the apparent value above stated.—Christianity is almost exclusively the religion professed by the nations of Europe. The three

principal denominations, Roman Catholic, Protestant, and Greek, correspond nearly to the three principal races, Latin, Teutonic, and Slavic. Geographically, the Roman Catholic is the dominant religion in the south and southwest, the Greek Catholic in the east and southeast, and the Protestant in the north and northwest. The number of Mohammedans is about 5,000,000 (3,500,000 in Turkey, the remainder in S. Russia), of Jews 5,000,000, of Buddhists about 10,000 (Mongolian nomadic tribes in S. Russia), and of pagans less than 1,000,000 (in the extreme north of Russia).—Popular education, measured by the proportion of schools and pupils to the entire population, is more general in the countries inhabited by the Teutonic race than among the Latin nations, and it holds the lowest place among the Slavic nations. In Germany, Sweden, Norway, and Denmark the proportion of pupils to the population is 1 to 6; in Belgium, 1 to 8·8; in Great Britain, 1 to 9·1; in France, 1 to 10·1; in Holland, 1 to 10·9; in Austria, 1 to 11·2; in Spain, 1 to 14·3; in Italy, 1 to 15·1; in Russia, 1 to 66·6.—Among the nations of Europe almost every form of government exists, from that having at its head an almost absolute personal ruler, to the several systems of the most restricted monarchy and the republic. The nature of the government of each is indicated in the following table, which exhibits the states of Europe as constituted in 1874, with their areas and the number of their population; and shows also their division, made for purposes of diplomatic intercourse, into four ranks according to their power and general status—a distinction which, however, is now less strictly marked than formerly:

NAMES OF STATES.	Form of government.	Area in sq. miles.	Population.	Date of census.
States of the first rank.				
Russia in Europe.....	Empire.....	2,059,225	71,195,405	1867
The German empire.....	Empire.....	205,619	41,055,139	1871
France.....	Republic.....	204,091	36,102,921	1872
The Austro-Hungarian monarchy.....	Empire.....	240,348	35,904,485	1869
Great Britain and Ireland.....	Kingdom.....	121,115	31,977,477	1871
Italy.....	Kingdom.....	114,295	26,716,809	1871
States of the second rank.				
Spain*.....	Republic.....	195,774	16,641,580	1867
Turkey in Europe (exclusive of Roumania).....	Empire.....	152,508	12,000,000	estimated.
Sweden and Norway.....	Kingdom.....	292,803	5,921,525	1870
Belgium.....	Kingdom.....	11,372	5,921,536	1869
Portugal.....	Kingdom.....	35,818	4,860,974	1868
Holland (with Luxemburg).....	Kingdom.....	13,678	3,855,541	1871
Denmark.....	Kingdom.....	55,021	1,864,496	1870
States of the third rank.				
Switzerland.....	Republic.....	15,991	2,669,147	1870
Greece.....	Kingdom.....	19,358	1,457,594	1870
States of the fourth rank.				
Roumania (under Turkish suzerainty).....	Principality.....	46,708	4,500,000	estimated.
Andorra.....	Republic.....	148	12,000	estimated.
Liechtenstein.....	Principality.....	62	8,820	1867
San Marino.....	Republic.....	22	7,303	1869
Monaco.....	Principality.....	6	8,127	1867

The present political systems of Europe are the product of nearly 20 centuries of strife and war among the different races inhabiting the continent. Though at certain periods

of peace political philosophers and statesmen have endeavored to demonstrate the existence of a certain balance of power, which, by keeping in check the ambition of conquerors, should serve as a guarantee for the continuance of the actual state of things, there

* Including the Canary islands.

† Including the Azores and Madeira.

are in the whole history of Europe scarcely any two succeeding generations during which this idea has been realized. There has always been an almost continuous shifting of boundaries irrespective of nationalities, and there is not one of the great powers that does not hold in subjection portions of other nationalities.—According to Kolb (*Handbuch der vergleichenden Statistik*, 1871), the yearly revenue of all the European states is \$1,712,000,000, of which sum \$764,000,000 belongs to the Teutonic states, \$579,000,000 to the Latin or Romanic states, \$292,000,000 to Russia, \$73,000,000 to Turkey and its dependencies, and \$4,380,000 to Greece. The average of revenue is: in Great Britain \$9 71 per head, in France \$8 73, in Austria \$5 26, in Germany \$4 08, in Switzerland \$4 12 (the lowest proportion in all Europe). The public debt of all European states amounted before 1850 to \$9,264,240,000, of which sum over \$6,000,000,000 was the public debt of the five great powers. But since then the extraordinary expenditure caused by the Crimean war of 1854–'6, the Franco-Sardinian war against Austria in 1859, the German-Italian war of 1866, and the Franco-Prussian war of 1870–'71, has increased the debt to near \$17,136,000,000. The paper currency of Europe amounted about 1850 to \$846,000,000, but within the last 20 years it has been so largely increased that its aggregate amount undoubtedly considerably exceeds \$1,000,000,000. The amount of coin was approximately stated at \$1,700,000,000 in 1850.—The military establishments of Europe include in time of peace about 2,500,000 men, kept at an expense of more than \$580,000,000. The proportion of the principal powers is: Germany, 420,000; Austria, 280,000; Great Britain (including the army in India), 250,000; France, 400,000; Russia, 600,000; Italy, 200,000; Spain, 200,000; Turkey and dependencies, 160,000. The navies of Europe consist of over 3,000 vessels, carrying over 30,000 guns, with 200,000 men, at a yearly expenditure of over \$125,000,000.

EUROTAS, the ancient name of a river of Greece, in Laconia, which rises in the mountains on the borders of Arcadia, about lat. 37° 15' N., lon. 22° 15' E., and, pursuing a general S. E. course, between the mountain ranges of Taygetus (now Pentadactylo) and Parnon (Malevo), empties into the gulf of Laconia. Its only tributary of consequence is the Cenus (Keesina), which joins it about a mile above the site of ancient Sparta. The Spartans rendered to the Eurotas divine honors. In modern times it has borne the names of Iri and Vasilii.

EURDYCE. I. In Greek mythology, the wife of Orpheus. She died from the bite of a serpent, and her husband followed her into the infernal regions, where Pluto, charmed by the lyre of Orpheus, gave him permission to take her back to earth, on condition that he would not look behind him while ascending. But, overcome by love or doubt, he glanced back at

her as they were about to pass the bounds of Hades, and saw her disappearing. (See ORPHEUS.) II. The daughter of Amyntas, son of Perdiccas III., king of Macedon, and of Cynane, daughter of Philip. On the death of Antipater in 319 B. C., she assembled an army and advanced against Polysperchon, who had succeeded him as regent. The presence of Olympias, the mother of Alexander, with the army of the latter, decided the contest against Eurydice, who was captured and thrown into prison, where she hanged herself.—Several others of the name are mentioned in ancient history.

EUSEBIUS, surnamed PAMPHILI, an ecclesiastical writer of the early church, born in Palestine about 265, died about 340. But little is known of his youth, save that he began his studies in Antioch, then visited the Thebaid, where he spent some time in completing his knowledge of Scripture and theology, after which he opened a school at Cæsarea. A splendid library founded or much enlarged by the bishop Pamphilus, his protector, enabled Eusebius to collect vast treasures of erudition. In the persecution of Diocletian (303) he fled from the city, but soon returned for the purpose of ministering to the wants of Pamphilus, who had been cast into prison, and was in 309 put to death. Eusebius assumed his name in memory of their friendship. Paulinus, bishop of Tyre, next gave him an asylum, but persecution drove him into Egypt, where he suffered imprisonment until the abdication of Diocletian set him free, and allowed him to return to Cæsarea, of whose church he became bishop in 315. About this time some points of resemblance between his theological views on the Trinity and those of the heresiarch Arius caused him to contract a friendship for the latter. At the council of Nice he sat at Constantine's right hand, and made the first draft of the Nicene creed. He subscribed the solemn profession of faith in the divinity of the Son, with a reservation founded on a confusion of the eternal birth of the Logos with the temporal birth of the incarnate Word, but he refused peremptorily to subscribe the decrees condemnatory of the Arian doctrine. A letter which he addressed to his diocesan after the council in explanation of his position and his views, together with his unremitting exertions in favor of Arius, caused him to be accused of heresy. His formulas and terminology continued to be employed by the Semi-Arians long after he had himself given expression to more orthodox opinions in his work *De Ecclesiastica Theologia*. In the long Arian controversies subsequent to the council of Nice he was the uncompromising opponent of Athanasius. He prevailed on the emperor to convene a council in 331 in Cæsarea, before which Athanasius was summoned, but refused to appear, and was accused by Eusebius of disobedience to the laws of the empire. His influence with Constantine caused a second council to be assembled in Tyre in 335, in which

he urged and obtained the deposition of Athanasius, and afterward procured his banishment to Gaul. On Sept. 14, 335, the bishops who had composed the council of Tyre assembled in Jerusalem for the dedication of a new church. Eusebius pronounced on the occasion his "Panegyric of Constantine," caused Arius to be admitted to the communion of the church, and wrote to the bishops of Christendom to inform them of these proceedings. Shortly after this the same prelates met in Constantinople under the leadership of Eusebius, who had Marcellus, bishop of Ancyra, condemned for Sabellianism, and besought in vain Alexander, bishop of the imperial city, to receive Arius solemnly to his communion. After witnessing the tragic death of Arius on this occasion, Eusebius returned to Cæsarea, and continued until his death with equal assiduity the publication of his great works and his opposition to Athanasius. He has been justly called the father of ecclesiastical history. Theological writers, both ancient and modern, are much divided with regard to his orthodoxy; some, like the historians Sozomen and Socrates, defend him strenuously; while others, with St. Jerome, Photius, and the seventh general council, condemn him as a heretic. His principal works are: "A Defence of Origen," in six books, in the first five of which the bishop Pamphilus coöperated; "Evangelical Preparation," in 15 books, and the "Evangelical Demonstration," in 20; *Chronicon*, a conspectus of universal history down to the 20th year of Constantine; "Ecclesiastical History," a "Life of Constantine;" five books "On the Incarnation;" "Commentaries on Isaiah;" *Onomasticon*, or a nomenclature of nations according to the Hebrew books; 30 books "Against Porphyrius;" "Topics;" "Topography of Judea and the Temple;" "Commentaries on the Psalms;" "Concordance of the Four Gospels;" "Commentary on the First Epistle to the Corinthians;" and "Treatise on the Fulfilment of Christ's Prophecies." His *Chronicon* was translated into Latin by St. Jerome, who continued it down to the sixth consulate of Valens and Valentinian; and it was published by Scaliger (2 vols. fol., Amsterdam, 1658). The whole work was in a fragmentary state until the discovery in 1784 of an Armenian version, which was published by Mai and Zohrab in 1818, and explained afterward by Niebuhr. His "Ecclesiastical History" was continued by Sozomen, Socrates, and Theodoret, and translated by Rufinus into Latin, and brought down to 395 (Rome, 1474). The principal editions are those of Stephens (Paris, 1544), Valois (Paris, 1659), Reading (Cambridge, 1720), Heinichen (3 vols. 8vo, Leipsic, 1827), and Burton (Oxford, 1838; reprinted, with an introduction by W. Bright, Oxford, 1872). It has been translated into French by Louis Cousin; into German by Hedio (1545) and Stroth (1778); and into English by Hammer (1577), Parker (1703),

Cater (1736), Dalrymple (1778), and Crusé (reprinted in Bohn's "Ecclesiastical Library"). A Greek edition (with Latin translation) of the complete works of Eusebius is contained in Migne's *Patrologia Græca* (Paris, 1857-'66, vols. xix. to xxiv.). The best Latin edition of the works then extant is that of Paris, 1581.

EUSTACHI, or **Eustachio**, **Bartolommeo** (Lat. **EUSTACHIUS**), an Italian anatomist, born probably at San Severino, near Salerno, died in Rome in 1574. He was a contemporary of Vesalius, and shares with him the merit of laying the foundation of the science of human anatomy. He extended the knowledge of the internal ear by giving a correct description of the tube between the throat and the ear, which has been called after him the Eustachian tube. He was also the pioneer in the accurate study of the anatomy of the teeth. His *Tabulæ Anatomice*, the text to which seems to have been lost, were first published in 1714 by Lancisi. Eustachi, who was professor of anatomy and physician to the cardinals Borromeo and Rovero, seems to have been so poor that he was unable to publish his works. Lauth remarks that if he had been able to publish them, anatomy would have attained the perfection of the 18th century 200 years earlier at least. A new edition of the *Tabulæ* was published by Albinus with an excellent commentary (Leyden, 1743). A Dutch commentary by Bonn appeared in Amsterdam in 1798; and one in German by Kraus in the same city in 1800.

EUSTIS, **William**, an American physician and politician, born in Cambridge, Mass., June 10, 1753, died in Boston, Feb. 6, 1825. He graduated at Harvard college in 1772, and subsequently studied medicine. He entered the American army during the revolutionary contest as a regimental surgeon, and served throughout the war in that capacity, or as hospital surgeon, being for some years stationed at the house opposite West Point in which Arnold had his headquarters. Upon the conclusion of the war he practised in Boston. Between 1800 and 1805 he was a representative in congress, and in 1809 he was appointed by President Madison secretary of war, a position which he retained until the surrender of the American forces under Gen. Hull to the British in 1812, when he was compelled to resign. In 1814 he was appointed minister to Holland, and after his return served again in congress between 1820 and 1823. In the latter year he was elected governor of Massachusetts, and died while holding that office.

EUTAW SPRINGS, a small affluent of the Santee river, in South Carolina, about 50 m. N. W. of Charleston, near which was fought, Sept. 8, 1781, a battle between the Americans under Gen. Greene and the British under Col. Stuart. The American force was about 2,000, that of the British about 2,300. Four miles from Eutaw a reconnoitering detachment of British cavalry was put to flight after a severe

skirmish. One mile from the British camp a body of infantry was encountered, which soon fell back. The action became general soon after 9 o'clock, and after a sharp contest the British were driven from their camp. The American soldiers had scattered among the tents of the enemy, plundering and drinking, when Stuart suddenly renewed the battle. Greene withdrew his troops out of range, deciding, as the enemy could maintain themselves but a short time, to wait and attack them on their retreat. During the night the British retreated toward Charleston; and the next day Greene advanced and took possession of the battle field, and sent detachments in pursuit of them. The British lost 133 killed and wounded, and 500 prisoners. The American loss was 535 in killed, wounded, and missing.

EUTERPE (Gr. *εὐ*, well, and *τέρπειν*, to delight), the inspirer of delight, one of the nine muses, daughter of Zeus and Mnemosyne (memory). She presided over lyric poetry, and played on the flute, of which she was the inventor; according to some, she also invented tragedy, which is more generally attributed to her sister Melpomene. She is usually represented as a virgin, crowned with flowers, with a flute in her hand, or various musical instruments around her, and sometimes as dancing.

EUTYCHES, a heresiarch of the 5th century, born about 380, died about 454. For many years he lived as a priest and archimandrite in the cloisters of Constantinople, where he had more than 300 monks under his direction. He was the head of the party opposed to Nestorius, who, in order not to confound the divine and human natures in Christ, had affirmed that there were in him two distinct persons. Eutyches, in his zeal for singleness of person in Christ, was led to maintain also that he possessed but one nature; whence his followers were called Monophysites. This opinion became popular in the Alexandrian church, where the doctrines of Nestorius had been most loudly condemned. The rising heresy was examined and condemned by a synod at Constantinople in 448. The influence of Eutyches and his friends obtained from Theodosius II. the reference of the matter to a general council to meet at Ephesus in 449 under the presidency of Dioscorus, a violent Eutychian. Here the triumph of Eutyches was secured by the outcries of monks, the threats of soldiers, and the overbearing violence of the president; and the most prominent hostile bishops were deposed. Pope Leo refused to recognize the acts of this council, which was known as the Latrocinium, or robber synod, and excommunicated Dioscorus; and at the general council of Chalcedon, in 451, both the doctrines of Nestorius and of Eutyches were condemned. In the 6th century a great revival of the doctrine took place under the auspices of the monk Jacob Baradaeus, who died bishop of Edessa. From him the sect took the name of Jacobites, who still constitute a numerous church in Egypt,

Syria, and Abyssinia. The emperor Heraclius sought to mediate between the Monophysites and Catholics, and promulgated a decree in 630, requiring the doctrine to be taught that there were two natures in Christ, but only a single will. Hence the name of Monothelites, the last offshoot of the heresy of Eutyches.

EUXINE SEA. See BLACK SEA.

EVAGORAS, king of Salamis in Cyprus, died about 374 B. C. His family claimed descent from Teucer, the reputed founder of Salamis, and had long held the sovereignty of that city, till expelled by a Phœnician exile. Evagoras recovered the kingdom in 410, and endeavored to restore in it the Hellenic customs and civilization, which had almost disappeared under the long domination of barbarians. He gave a friendly reception to the Athenian general Conon, after the defeat at Ægospotamos; it was by his intercession that the king of Persia permitted the Phœnician fleet to aid Conon; and he himself commanded the Cypriote squadron which joined Conon and Pharnabazus at the battle of Cnidus (394). For these services a statue was erected to him at Athens in the Ceramicus, by the side of that of Conon. His increasing power attracted the jealousy of the Persian king Artaxerxes II., who declared war against him. Evagoras immediately extended his power over almost the whole of Cyprus, ravaged the coasts of Phœnicia, excited the Cilicians to revolt, and even captured the city of Tyre; but a Persian army, landing in Cyprus, recaptured the island and besieged Evagoras in his capital. He was saved only by the dissensions of his enemies, and concluded in 385 a peace by which the sovereignty of Salamis was secured to him. He survived this treaty ten years, and died by assassination.

EVAGRIUS, a Syrian church historian, born about 536, died in Constantinople, probably early in the 7th century. He was an eminent lawyer in Antioch, but devoted much of his time to scholastic labors, and wrote in Greek an ecclesiastical history, in continuation of previous works by other authors, extending from 431 to 593, which is recognized as a high authority. The best edition is by Reading (3 vols., Cambridge, 1720). Meredith Hanmer furnished an English translation with a biography of Evagrius to Bagster's "Ecclesiastical Historians," subsequently included in Bohn's "Ecclesiastical Library" (London, 1851).

EVALD, or **Ewald, Johannes**, a Danish poet, born in Copenhagen, Nov. 18, 1743, died there, March 17, 1781. He early displayed his love of adventure by an attempt to go to sea, and afterward entered the army of Frederick the Great, which he immediately abandoned, joining that of Austria; but he was induced to return to Copenhagen, where he studied theology, and passed his examination in 1762. Disappointed in love, he devoted himself to literature. His first composition, "The Temple of Fortune, a Vision," was followed in 1766 by a poem on the death of Frederick

V. In 1769 appeared his lyrical drama of "Adam and Eve." His tragedy of *Rolf Krage* (1770) was the first attempt to dramatize the ancient history of Denmark, and bears evidence of the careful study of both Ossian and Shakespeare. About this time he became lame, and poverty, neglect, and intemperance added to his misfortunes. He was eventually deserted even by his mother, and the last two years of his life were spent in the house of a benevolent friend. But his literary activity remained undiminished, and in 1771 and 1772, while in the greatest distress of mind and body, he wrote even humorous plays, which were very successful. His most celebrated work, *Balders Død* ("Baldur's Death"), a drama devoted to the heroic reminiscences of Scandinavian mythology, appeared in 1773. His finest lyrical poem, "The Fishermen," appeared in 1778. He also wrote a famous national song of Denmark, and some works in prose. He began to prepare his poetical works for publication, but the edition was completed only after his death (4 vols., Copenhagen, 1781-'91; best ed., by Liebenberg, 8 vols., 1850-'55).

EVANGELICAL ALLIANCE, a religious association among different denominations of Protestants in Europe and America. A convention, called for the formation of such an alliance, met in Freemason's hall, London, England, Aug. 19, 1846. It consisted of about 800 clergymen and laymen from France, Belgium, Germany, Switzerland, Italy, Turkey, Great Britain and Ireland, the United States, and Canada, representing 50 denominational connections. The convention sat 13 days, and adopted the basis of the religious doctrines held in common by evangelical Protestants, viz.: the inspiration and sufficiency of the Scriptures; the right of private judgment in interpreting the Scriptures; the unity and trinity of the Godhead; human depravity; the incarnation and atonement of Christ; justification by faith alone; conversion; eternal rewards and punishments; the divine institution of the ministry, and of baptism and the Lord's supper. It was declared that this summary of doctrines was not to be regarded in any formal or ecclesiastical sense as a creed or confession, nor its adoption as an assumption of the right to define the limits of Christian brotherhood, or that the doctrines adopted embrace the whole of important truth. The convention recommended the formation of national branches in the different countries of Europe and America; the object of the association being to display the substantial union of Protestants of different countries and names, and to strengthen and enlarge that union. The recommendation was followed by the formation of coördinate societies, independent of each other, but united in object and sympathy, in Great Britain and Ireland, France, Germany, Holland, Switzerland, Sweden, America, and among the missionaries in Turkey, Persia, the East and West

Indies, Palestine, Australia, New Zealand, and Africa. Besides the convention in which the alliance was formed, six international conferences have been held at irregular intervals: in London, 1851; Paris, 1855; Berlin, 1857; Geneva, 1861; Amsterdam, 1867; and New York, 1873. These conferences have been largely attended, the last (Oct. 2-12, 1873) especially so, and have embraced many of the most distinguished members of the respective denominations, both of the clergy and laity. Besides the regular sessions of the conferences, during their progress special meetings have been held with reference to particular countries, in which the languages of these countries were used, and their wants brought before the Christian world. At the Geneva conference in 1861 a special meeting was held with reference to the civil war in America, for the purpose of bringing the true aspects of the war before European Christians. The alliance has for several years united, through its committees, in recommending a time and subjects for special prayer, which have been generally observed by those in sympathy with the alliance throughout the world; the first week in January being the time selected, and the subjects for each day of the week being considered in all lands. The alliance has exerted an influence in favor of religious liberty in Spain, Italy, Austria, Sweden, and Turkey; and in 1871 a committee representing different branches in Europe and America proceeded to Russia, and memorialized the czar in behalf of the Protestants in the Baltic provinces.—Reports of the proceedings of the several conferences have been published under the following titles: "The Religious Condition of Christendom" (London, 1852); "The Religious Condition of Christendom" (London, 1859); "The Geneva Conference of the Evangelical Alliance" (Edinburgh and London, 1862); and *Evangelische Alliantie* (Rotterdam, 1867), and "Proceedings of the Amsterdam Conference" (London, 1868).

EVANGELICAL ASSOCIATION, an ecclesiastical body, sometimes erroneously called the German Methodist church, probably because its confession of faith and its polity are very similar to that of the Methodist Episcopal church, while its members are chiefly Germans or of German descent. It took its rise in the eastern part of Pennsylvania in the year 1800, and resulted from an organization into classes and congregations of the disciples of the Rev. Jacob Albright, who, being impressed by the general decline of religious life, and the corruption of doctrines and morals that prevailed in the German churches in that portion of the country, undertook about 1790 to work a reform among them. The effect of his first efforts encouraged him to travel through a great part of the country, preaching in churches, in schools or private houses, in the public roads, &c. He soon found it necessary to unite his converts, scattered over several counties, into small societies for mutual support and sym-
 pa-

thy. At a meeting called for the purpose of consulting upon the best measures to be adopted, the assembly unanimously elected Mr. Albright as their pastor, authorizing him to exercise all the functions of the ministerial office over them, and declared the Bible to be their rule of faith and practice. This organization was soon after considerably improved by the adoption of a creed and rules for church government. In the course of time annual conferences were held; and in 1816 a general conference met for the first time in Union co., Pa., which consisted of all the elders in the ministry. Since 1843 a general conference, composed of delegates elected by the annual conference from among their elders, has held quadrennial sessions. This body constitutes at once the highest legislative and judicial authority recognized in the church. The ministry is divided into two orders, deacons and elders; and, faithful to the principles and example of their founder, they practise itinerancy. Its highest permanent order is the eldership; for, although the society has its bishops and presiding elders, yet these, to be continued, must be reelected every four years; and if not reelected, they hold no higher rank or privilege than that of an elder. For the first 25 years of its existence the society struggled against violent opposition, but since then it has made rapid progress, so that in 1873 it comprised 15 annual conferences, consisting of over 600 itinerant and 400 local preachers. The church has hardly any congregations in the New England and the southern states, and is most numerous in Pennsylvania and the northwestern states. It has two conferences outside of the United States, Canada and Germany, both established in 1863. The aggregate membership in 1873 was 83,195, an increase over the preceding year of 2,505. The membership of the Canada and Germany conferences was about 8,500. The institutions of learning sustained by the church in 1872 were, the Northwestern college in Naperville, Ill.; the Union seminary in New Berlin, Pa.; the Blairstown seminary in Blairstown, Md.; and the Ebenezer orphan institution at Flatrock, Ohio. Its publishing house at Cleveland, Ohio, issues six periodicals, three in German and three in English, besides which two periodicals are published in Germany. The society forbids its ministers and members the use of intoxicating liquors as a beverage, and refuses church fellowship to manufacturers and vendors of them. In theology it is Arminian, but holds the essential doctrines of the gospel as they are held in common by the various evangelical churches, with all of whom it aims to cultivate a fraternal spirit. The first volume of a "History of the Evangelical Association" has been published by the Rev. W. W. Orwig.

EVANGELIST (Gr. εὐ, well, and ἀγγελλειν, to announce), one who brings good tidings. Hence the writers of the four Gospels are called the evangelists, because they in a preëminent sense

declare the glad tidings of salvation by Christ. Evangelists were early designated as a particular class of religious teachers in the Christian church, next in order to the apostles, and under their direction; not attached to any particular church or place, but going forth to preach the gospel wherever they were called or sent, and to travel among the infant churches, ordain their ordinary officers, and finish the work the apostles had begun. The primitive order of evangelists, distinct from other public religious teachers, is supposed to have been merely temporary, like that of apostles and prophets; but the class of duties and services which they performed seems to have fallen more especially on the missionaries of modern days.

EVANS, Sir De Laey, a British general, born at Moig, Ireland, in 1787, died in London, Jan. 9, 1870. Entering the army as an ensign, he served three years in India, and subsequently distinguished himself in Portugal and Spain in the campaigns of 1812-'14. He served in America as a brevet lieutenant colonel, was at the battle of Bladensburg, Aug. 24, 1814, and at the head of 100 men, acting under orders from Gen. Ross, forced the capitol at Washington. Of this expedition he wrote an account, "Facts relating to the Capture of Washington," &c. (8vo, London, 1829). He also took part in the attack on Baltimore. In December, 1814, and again in January, 1815, he was wounded before New Orleans, and was sent home. He recovered in time to join Wellington at Quatre Bras and Waterloo, and was at the subsequent investment and capitulation of Paris. In 1828 he published a pamphlet "On the Designs of Russia" in the East, which excited much attention, and was translated and published in Paris. In 1830 he was for a few months a member of parliament for Rye, and was reelected in 1831. From 1833 to 1841 he represented Westminster. In 1835 he commanded the British auxiliary legion of 10,000 men in aid of the queen of Spain against Don Carlos. He was in Spain till the spring of 1837, and for his exploits at Bilbao, San Sebastian, and Irun he was made a knight commander of the bath, and received the cross of San Fernando and San Carlos. In 1846 he was reelected to parliament for Westminster, and retained this seat till 1865. In the Crimean war, as lieutenant general, he commanded the second division of the British army, and for his services at the Alma and at Inkerman he received the thanks of parliament, and the grand cross of the bath, and was made a grand officer of the legion of honor.

EVANS, Edward P., an American scholar and author, born at Remsen, N. Y., Dec. 8, 1833. His father was a Welsh Presbyterian clergyman, who emigrated to the west in 1842. Edward graduated at the university of Michigan in 1854, taught an academy in Hernando, Miss., one year, and then became professor in Carroll college, Waukesha, Wis. From 1858 to 1862 he travelled in Europe, and studied

in the universities of Göttingen, Berlin, and Munich. In the autumn of 1862 he became professor of modern languages in the university of Michigan, which position he resigned in 1870 to travel in Europe and collect materials for a history of German literature. He has published translations of Stahr's life of Lessing (2 vols., Boston, 1866) and Coquerel's "First Historical Transformations of Christianity" (Boston, 1867); *Abriss der deutschen Literaturgeschichte* (New York, 1869); and various philosophical articles in periodicals.

EVANS, Frederick William, presiding elder of the community of Shakers at New Lebanon, Columbia co., N. Y., born in Leominster, England, June 9, 1808. His father settled in the United States in 1820, and apprenticed him to a hatter in New York. He was a diligent student in his leisure hours, was attracted by the theories of Owen and Fourier, and after a brief visit to England joined the Shaker community, whose leader he became in the United States. He has published "Tests of Divine Revelation," "Anne Lee, or Shakers and Shakerism," "Compendium," "Autobiography of a Shaker," and "Religious Communism."

EVANS, Lewis, an American geographer and surveyor, born about 1700, died in June, 1756. During an active professional life he collected many materials for a map of the British North American colonies, and in 1749 published one of the middle colonies, chiefly of New York, New Jersey, and Delaware, and of the Indian country adjacent. A second edition appeared in 1755, much enlarged, and containing in addition Virginia, Maryland, Pennsylvania, and a part of New England. He also published "Geographical, Historical, Political, Philosophical, and Mechanical Essays" (No. 1, Philadelphia, 1755; No. 2, London, 1756). A new edition of his map appeared in 1776.

EVANS, Marian. See LEWES, MARIAN EVANS.

EVANS, Oliver, an American inventor, born in Newport, Del., in 1755, died in New York, April 21, 1819. He was apprenticed to a wheelwright, and before he had reached the age of manhood the construction of a land carriage to be propelled without animal power began to occupy his attention. At the age of 22 he invented a machine for making card teeth which superseded the old method of manufacturing them by hand. Two years later he entered into business with his brothers, who were millers, and in a short time invented the elevator, the conveyor, the drill, the hopper-boy, and the descender, the application of which to mills worked by water power effected a revolution in the manufacture of flour. In 1786-'7 he obtained from the legislatures of Maryland and Pennsylvania the exclusive right to use his improvements in flour mills, and Maryland also gave him a similar privilege with respect to steam carriages. It was not till 1799 or 1800 that he was able to set about the construction of a steam carriage; but finding that his steam engine differed in form as well

as in principle from those in use, it occurred to him that it could be patented and applied to mills more profitably than to carriages; and in this he was completely successful. This was the first steam engine constructed on the high-pressure principle; and to Evans, who had conceived the idea of it in early life, and in 1787 and again in 1794-'5 had sent to England drawings and specifications, the merit of the invention belongs, although it has been common to assign it to Vivian and Trevithick, who had had access to Evans's plans. In 1803-'4, by order of the board of health of Philadelphia, he constructed the first steam dredging machine used in America, consisting of a flat scow with a small engine to work the machinery for raising the mud. The machine, which he named the "Orukter Amphibolos," propelled itself on wheels to the Schuylkill, a distance of $1\frac{1}{2}$ m., was fitted with a paddle wheel in the stern, and navigated the river to its junction with the Delaware. This is believed to have been the first instance in America of the application of steam power to the propelling of land carriages. He predicted the time when such carriages would be propelled on railways of wood or iron, and urged the construction of a railroad between Philadelphia and New York, but was always prevented by his limited means from prosecuting his mechanical experiments to the extent he desired. He was the author of "The Young Engineer's Guide" (8vo, Philadelphia, 1805; translated into French, Paris, 1821-'5 and 1838), and "Miller and Millwright's Guide" (8vo, Philadelphia, 1797, 1807, 1818; and 8vo, Paris, 1830; 14th ed., with additions and corrections by Thomas P. Jones, and a description of an improved merchant flour mill by C. and O. Evans, 8vo, Philadelphia, 1853).

EVANSTON, a township of Cook co., Illinois, on Lake Michigan and on the Chicago and Northwestern railroad, 12 m. N. of Chicago; pop. in 1870, 3,062. It is the seat of three Methodist educational institutions, viz.: the Northwestern university, organized in 1854, and having in 1872 11 professors and instructors, 452 students, and a library of 22,000 volumes; the Garrett Biblical institute, established in 1856, which in 1872 had 6 professors, 64 students, a library of 3,000 volumes, and an endowment of \$424,000; and the Evanston college for ladies, organized in 1871, having 12 instructors and 250 students.

EVANSVILLE, a city, port of entry, and the capital of Vanderburg co., Indiana, 144 m. S. W. of Indianapolis, built on high ground on the N. bank of the Ohio river, nearly 200 m. from its mouth and the same distance below Louisville, Ky.; pop. in 1850, 3,235; in 1860, 11,484; in 1870, 21,830, of whom 6,276 were foreigners and 1,427 colored. The river at this point describes a half-moon, whence Evansville is sometimes called the "crescent city." In the vicinity are found coal and iron ore. The city contains a handsome court house, city hall,

United States marine hospital, an opera house, and several hotels. The United States government is also erecting a large building to accommodate the post office, United States courts, and the custom house. The Wabash and Erie canal extends to Toledo, Ohio, a length of 462 m.; the Evansville and Crawfordsville railroad connects, *via* Terre Haute, with the principal railroads of the state; and the St. Louis and Southeastern railroad affords communication with that city. The Lake Erie, Evansville, and Southwestern railroad is completed to Boonville, the county seat of Warrick co. Evansville is a place of great commercial activity, and its manufactures are important. In 1871 the number of arrivals and departures of vessels was 2,586; value of imports, \$169,588 30, the principal items being railroad iron, hardware, and coffee; amount of duties collected, \$69,771 72. The principal articles of export are grain and flour, pork, salt, whiskey, cement and lime, cotton, hay, dried fruit, tobacco, and railroad iron. For the year ending June 30, 1872, there were 70 vessels of 10,047 tons belonging to the port, of which 56 of 9,046 tons were steamboats, and 14 of 1,001 tons canal boats; built during the year, 8 steamboats of 721 tons. The total value of manufactures in 1872 was \$5,469,763, consisting of furniture, flour and meal, machinery, planing mill products, stoves and hollow ware, malt liquors, saddlery and harness, clothing, leather, marble and dressed stone, cotton goods, cooperage, tinware, brick, &c. There are four national banks, with an aggregate capital of \$1,950,000. The city is divided into twelve wards. Terms of the United States circuit and district courts are held here. The assessed value of property in 1851 was \$1,907,632; in 1861, \$5,385,675; in 1871, \$20,528,075; taxation in 1871, \$265,945. There are nine large public school buildings belonging to the city, the high school building being the finest in the state. The number of separate departments in 1872 was 49, viz.: a high school, 8 grammar, and 40 primary, having 73 teachers and 4,583 pupils. The library association has 3,500 volumes. There are four daily newspapers (two German), one tri-weekly, five weekly, and one semi-monthly. There are 24 churches, viz.: 4 Baptist, 1 Christian, 2 Episcopal, 1 Evangelical German, 3 Lutheran, 6 Methodist, 4 Presbyterian, and 3 Roman Catholic. Evansville was laid out in 1817.

EVAPORATION, the dissipation of bodies by the volatile particles at their surface assuming the form of vapors and disappearing in the space around them. Liquids manifest this property most sensibly. Mercury exhibits it at temperatures exceeding 60° F., as is shown by the invisible fumes forming an amalgam on the surface of a bit of gold leaf, suspended for some days over the surface of the metal; and at temperatures far below this limit the vapor of mercury is present in the vacuum of the upper portions of the tubes of barometers and thermometers. Many solid bodies are subject to

it; camphor, ice, snow, musk, &c., waste away by their particles being taken in invisible vapor into the surrounding atmosphere. It is a part of the process provided by nature for restoring to the earth, through the medium of the clouds, the waters which have drained from its surface into the sea, and those also held in the soil, or upon the leaves of the forest. Once having performed their office, they are recalled by the process of evaporation, purified by it of their earthy contaminations, and are again poured out for the refreshment of vegetable and animal life. (See ATMOSPHERE, DEW, HEAT, and ICE.) The following table gives some relations between the vapor of water and the liquid:

Temperature, Fahrenheit.	Volume of vapor containing a unit of water.	Mechanical force required to vaporize, in foot pounds.
-4°	650,588	1,395
+92	182,323	1,438
50	102,670	1,565
100	22,518	1,792
140	7,987	1,847
212	1,696	2,073
250	896	2,192

Evaporation takes place in ordinary temperatures only from the surface of objects. It is greater in a warm dry air than when the temperature is low, or the atmosphere is already nearly filled with vapor. The more moisture is taken up into the same body of air, the more the process is retarded, until at length it is entirely checked. It is renewed by new supplies of dry air. The most favorable natural conditions for its rapid action are presented on the Atlantic ocean under the trade winds, which from the hot deserts of Africa blow across to the Cordilleras. The Amazon and the Orinoco are the fruits of the evaporation thus produced. The vapors that are continually ascending from moist surfaces are for the most part invisible, like those exhaled by breathing. Their existence is proved by instruments called hygrometers, hygrometers, and psychrometers; and at times they become visible, as when in clear frosty weather they rise copiously from the surface of pools fed by deep springs, and are seen congealed in white clouds, like the vapors of the breath under the same conditions. But unless deprived of their heat they possess the properties of gaseous bodies; a given bulk of air or of other gases takes up the same quantity of a vapor as would be received in a vacant space of the same extent and temperature. This was conclusively proved from the experiments of Dr. Dalton. It results that no more vapor can be received into any space after the weight of that already there amounts to the elastic force of the vapor at the temperature of the surface which generates it; in proportion as the air approaches this state of complete saturation it is said to be more moist, and evaporation proceeds more slowly. Increase of temperature adds to the elasticity of the vapor and promotes evaporation; cold reduces

the elasticity and promotes precipitation. Pressure does not affect the capacity of air to contain vapor; but evaporation proceeds more slowly by its increase. If it be removed, as when a liquid is placed in an exhausted receiver of an air pump, evaporation goes on with great rapidity. Ether may thus at ordinary temperatures be thrown into ebullition. A difference is observed in the tendency of different liquids to pass into vapor; the lower their boiling point, the more rapid is their evaporation; but it is also observed that the vapor thus easily produced is correspondingly less rare, occupying less space than that requiring a greater expenditure of heat for its evolution. The density of alcoholic vapor is 2.5 times greater than that of water. Dalton discovered that the presence of air or any gas impeded evaporation by the resistance its particles opposed to the circulation of the vapor; but whether any gas were present or not, the same amount of vapor would always be formed at the same temperature. The effect of the air was seen in the longer time required to fill the space with the amount of vapor belonging to the temperature. Vapors have a greater capacity for heat than their particles when condensed into liquid or solid form. In their formation consequently they abstract heat from surrounding bodies, producing an amount of cold corresponding to the rapidity of the process. This principle is applied in the water and wine coolers used in hot countries. The water with which they are filled, and in which the wine bottles are placed, filters through the porous vessels and evaporates from their surface, cooling all the contents. A similar effect is experienced in the animal body by rapid evaporation. The heat generated by the chemical actions going on within is taken off by the vapor formed at the surface. Damp clothes furnish the means for the production of much vapor and consequent reduction of temperature, often to an injurious extent. The heat abstracted by vapor in its formation is given out on its condensation. In low pressure steam engines it is economized by being transferred in the condensers to the water that is returned to the boilers.—Hygrometers and hygrometers, already referred to, are instruments designed, the first for detecting the presence of moisture in the atmosphere, and the second for determining either the temperature at which the air under observation begins to shed its moisture, called the dew point, or else the temperature of evaporation. Either of these and the normal temperature of the air being known, the elastic tension of the atmospheric vapor, and the amount of moisture in a given quantity, are approximately ascertained by reference to tables constructed for this purpose. (See DEW POINT, and HYGROMETRY.) Evaporation is accompanied with ebullition when the elastic force pressing upon the surface of a liquid is less than that due to the temperature of this liquid. (See BOILING POINT.)—The principles devel-

oped by researches in the evaporation of liquids have been applied in a variety of ways to facilitate and render more economical several practical operations. Sirups are evaporated, as in the refining of sugar, in vacuum pans, or vessels in which the atmospheric pressure may be partially taken off by air pumps. A low degree of heat only is thus required, and the risk of overheating and burning the sirup is avoided. Extracts are conveniently prepared on the same principle. But when it is desirable to effect the boiling at high temperatures, as for digesting bones and subjects difficult to dissolve, the evaporation is prevented by the vapor being confined, so as to exert its elastic force upon the surface of the fluid. Thus the escape of more steam is checked until, by greater heat, its elastic force is made greater than that upon the surface. By this method the temperature of the water has been raised to more than 400° F. Rapid evaporation has been promoted in salt works and in bleacheries by causing currents of air to blow over the extended surfaces of the liquids, thus constantly bringing new portions of dry air to absorb fresh quantities of moisture.—As evaporation cannot take place unless the elasticity of the vapor can overcome the superficial tension of the liquid, and as this tension depends to a large extent on the nature of the gas in contact with the free surface of the liquid, it follows that the boiling point must vary with every circumstance. Thus Dufour, having dropped some pure water into a mixture of oils having nearly the same density, was able to raise the temperature to 356° F., and still saw drops of water swimming in the mixture, although the tension of the aqueous vapor at this temperature is about 147 lbs. to the square inch. When water falls upon red-hot surfaces it separates in spherical drops, which dance around upon the metal, apparently without touching it, and thus continue without evaporating much longer than the fluid would if exposed to the same degree of heat under other circumstances. A platinum crucible brought nearly to a white heat may be almost half filled with water introduced drop by drop, which will continue in this state for some minutes without perceptible evaporation. On cooling the crucible, the liquid suddenly begins to boil, and discharges a volume of vapor. While in the spheroidal state drops are seen to be supported on an atmosphere of vapor, which prevents their contact with the surface of the metal. Most liquids, except oils which are decomposed by the heat, display the same phenomena. Their temperature while in this condition is not only much less than that of the surface upon which they rest, but is also below their own boiling point; and if they are already boiling when dropped upon the heated surface, the temperature falls to a certain point, which appears to be a fixed one for each liquid in this condition. Water remains at 205°; alcohol, which boils at 173°, falls at least 3°; ether, which boils at 95°, falls at least 5°. The tem-

perature of the heated surface at which liquids are caused to assume this condition has been found, for water, to be 340° or more; for alcohol, 273° ; and for ether, 140° . The check upon evaporation is very remarkable. A quantity of water which would ordinarily disappear in vapor in one minute at the temperature of 212° , has been kept from total dispersion nearly an hour in a metallic vessel heated nearly red.

EVARTS. **I. Jeremiah**, secretary of the American board of commissioners for foreign missions, born in Sunderland, Vt., Feb. 3, 1781, died in Charleston, S. C., May 10, 1831. He graduated at Yale college in 1802, and after some time spent in teaching, he studied law, was admitted to the bar in 1806, practised his profession in New Haven for about four years, and from 1810 to 1820 edited the "Panoplist," a religious monthly magazine published at Boston. In 1812 he was chosen treasurer of the American board of commissioners for foreign missions, and in 1820, when the "Panoplist" was discontinued, and the "Missionary Herald" was issued by the board in its stead, he took charge of the latter periodical. He was chosen corresponding secretary of the board in 1821, and retained that office until his death. He wrote 24 essays on the rights of the Indians, under the signature of "William Penn," which were published in 1829.—See "Memoirs of Jeremiah Evarts," by E. C. Tracy (8vo, Boston, 1845). **II. William Maxwell**, an American lawyer, son of the preceding, born in Boston, Feb. 6, 1818. He graduated at Yale college in 1837, studied in the Harvard law school, and was admitted to the bar in New York in 1841. He received the degree of LL. D. from Union college in 1857, from Yale in 1865, and from Harvard in 1870. In the impeachment trial of President Johnson, in the spring of 1868, Mr. Evarts was principal counsel for the defendant. From July 15, 1868, to the close of President Johnson's administration, he was attorney general of the United States. In 1872 he was counsel for the United States in the tribunal of arbitration on the Alabama claims at Geneva. Of Mr. Evarts's public addresses there have been published "Centennial Oration before the Linnæan Society of Yale College" (8vo, New Haven, 1858), and "Address before the New England Society" (8vo, New York, 1854).

EVE (Heb. *'Havvah*), in Scriptural history, the name given by Adam to his wife. It is derived from the verb *'hayoh*, to live, and was applied to her as "the mother of all living." She was created to be a help meet for Adam, and was placed by God with him in Eden; but yielding to the temptation of the serpent, and tasting and leading Adam to taste the forbidden fruit, she was with him driven forth from paradise, and was doomed to sorrows and sufferings, especially in the birth of her offspring. She was the mother of Cain, Abel, and Seth; and with the birth of the last her history ceases.

EVECTION (Lat. *evectio*, a carrying out), the principal perturbation of the moon in longitudes, causing her to be alternately nearly three times her own breadth in advance of, and behind, her mean place. The fact of evection was discovered by Ptolemy, but its cause was unknown before the law of gravitation was discovered. It arises from the disturbing influence of the sun, alternately elongating the moon's orbit and reducing its eccentricity, as the end or side of the orbit is toward the sun.

EVELYN, John, an English author, born in Wotton, Surrey, Oct. 31, 1620, died there, Feb. 27, 1706. He was educated at Balliol college, Oxford, studied law, and served for a short time in 1641 as a volunteer in the Netherlands. He returned to England as the civil war was breaking out, and joined the royal army, but after the king's retreat to Gloucester travelled through France and Italy. He returned in 1651, assisted in the restoration of 1660, and was received with favor at court. He was one of the founders of the royal society in 1662, a member of the first council, and during his life a constant contributor to its "Transactions." Upon the breaking out of the Dutch war in 1664 he was a commissioner to tend the sick and wounded, and he was one of the first members of the board of trade. The English naval commissioners dreading a scarcity of naval timber in the country, at the request of the royal society Evelyn wrote his "Sylva, or a Discourse on Forest Trees, and the Propagation of Timber in his Majesty's Dominions" (folio, 1664). It induced many landholders to plant an immense number of young oak trees, which furnished the ship yards of the next century. He published many other popular works on learned subjects, on painting, sculpture, architecture, and medals, and was one of the first in England to treat gardening and planting scientifically. The most valuable of his works is a diary, in which during the greater part of his life he related the events in which he was interested. This was edited by W. Brady (4 vols. 4to, 1818), and contains much curious and minute information concerning the manners and society of his time. An enlarged edition was edited by John Forster (4 vols. 8vo, 1859), and editions in 1 vol. 8vo appeared in 1870 and 1871.

EVERDINGEN, Aldert van, a Dutch marine and landscape painter, born in Alkmaar in 1621, died there in 1675. He excelled in painting wild and rugged scenery. Having been shipwrecked on the coast of Norway during a voyage to the Baltic, he employed the time while the vessel was repairing in making sketches of rocks, waterfalls, and other prominent features of a mountainous country. His sea pieces, particularly those in which storms are represented, are very effective, being painted with a broad, free pencil, and carefully colored. He also etched upward of 100 prints of Norwegian scenery, besides 56 illustrations to the fable of "Reynard the Fox."

EVERETT, Alexander Hill, an American diplomatist and author, born in Boston, March 19, 1792, died in Canton, China, May 29, 1847. He graduated at Harvard college in 1806 with the highest honors of his class, although he was the youngest of its members, and in 1807 began to study law in the office of John Quincy Adams. He was attached to Mr. Adams's legation at St. Petersburg in 1809-'11, and after visiting England and France commenced the practice of the law in Boston in 1812. He contributed articles to some of the periodicals of the day, and wrote for one of the Boston journals a series of political papers sustaining the policy of the administration in the war with Great Britain. In 1814 he was secretary of legation to the Netherlands, and on the retirement of Mr. Eustis from that mission in 1818, he was appointed his successor, with the rank of *chargé d'affaires*. During his residence in the Netherlands he was a frequent contributor to the "North American Review," mostly upon subjects drawn from French literature, and prepared a work which was published in 1821 in London and Boston, under the title of "Europe, or a General Survey of the Political Situation of the Principal Powers, with Conjectures on their Future Prospects." This work attracted much attention, and was translated into German, French, and Spanish. In 1822 he published at London and Boston a work entitled "New Ideas on Population," in opposition to the views of Malthus. In 1824 he returned to the United States, and in 1825 was appointed minister plenipotentiary to Spain. While at this post, as the representative of the only government that had then acknowledged the independence of the South American republics, he became the medium of communication between them and their mother country, and their virtual representative. Here he wrote a work entitled "America, or a General Survey of the Political Situation of the Principal Powers of the Western Continent, with Conjectures on their Future Prospects" (Philadelphia, 1827; London, 1828), intended as a complement to his former publication on Europe. This was also translated into German, French, and Spanish. He promoted the Spanish studies of Washington Irving, who was an *attaché* of his legation, and also aided Prescott in procuring materials for the history of Ferdinand and Isabella. In 1829 he returned home, and for about five years conducted the "North American Review" as editor and proprietor. He defended in several elaborate papers the policy of a protective tariff, and some articles, in which he reviewed the course and policy of the federal and democratic parties from a historical point of observation, are among his ablest productions. He was chosen to the senate of Massachusetts in 1830, and continued a member of that or the other branch of the legislature for the ensuing five years. He had thus far been a member of the national republican or whig

party, and had drafted the address reported by the convention which in 1831 nominated Henry Clay for the presidency; but during the second term of Jackson's presidency, and after the proclamation against nullification, he became an adherent of the administration. In 1836, 1838, and 1840 he was an unsuccessful candidate for congress. In 1840 he was sent by the government upon a confidential mission to Cuba, and passed two months at Havana. In June, 1841, he accepted the office of president of Jefferson college, Louisiana, but declining health soon compelled him to return to the north. He still continued his contributions to periodical literature, and a duodecimo volume of selections from his critical and miscellaneous essays was published in Boston in 1845, and a second series in 1847. A small volume of poems, original and translated, was published by him in New York in 1845. In the same year he was appointed commissioner to China, and set out for his post in July; but on arriving at Rio de Janeiro his infirm health compelled him to return home. He sailed a second time in 1846, and arrived in Canton, where he was prostrated by disease.

EVERETT, Edward, an American statesman, orator, and author, brother of the preceding, born in Dorchester, Mass., April 11, 1794, died in Boston, Jan. 15, 1865. He entered Harvard college in 1807, and graduated in 1811, at the age of 17, with the highest honors. While an undergraduate he was the principal conductor of a magazine published by the students, called the "Harvard Lyceum." He became a tutor in the college, and at the same time pursued his studies in divinity. In 1812 he delivered a poem before the Phi Beta Kappa society on American poets. In 1813 he was settled as pastor over the Brattle street church in Boston, and immediately won reputation by the eloquence and power of his discourses. In 1814 he published a "Defence of Christianity," in reply to the work of George Bethune English entitled "The Grounds of Christianity Examined, by comparing the New Testament with the Old." In the same year he was chosen Eliot professor of Greek in Harvard college, and to qualify himself for his duties, in the spring of 1815 he entered upon an extended course of European travel and study. After a brief stay in England, he went to the university of Göttingen, where he remained for two years. In the winter of 1817-'18 he was at Paris. In the spring of 1818 he went to England, where he became acquainted with many of the leading men of the day, including Scott, Jeffrey, Campbell, Mackintosh, Romilly, and Davy. Returning to the continent, he passed the winter in Italy, and thence made a journey into Greece, returning through Wallachia and Hungary to Vienna. During his residence in Europe, his range of study embraced the ancient classics, the modern languages, the history and principles of the civil and public law, and a comprehensive examina-

tion of the existing political systems of Europe. Upon his return home, in 1819, he entered upon the duties of his professorship, and delivered to the students a series of lectures upon Greek literature and ancient art, which were afterward repeated before large audiences in Boston. He also became editor of the "North American Review," which he conducted till 1824, contributing to it about 50 articles, to which may be added about 60 more contributed while the "Review" was edited by his brother and others succeeding him. He also prepared a translation of Buttmann's Greek grammar, and a Greek reader based upon that of Jacobs. In 1824 he delivered a discourse before the Phi Beta Kappa society on the "Circumstances favorable to the Progress of Literature in America," at which Lafayette sat by his side. This was the first of a series of discourses pronounced by him on public occasions, embracing every variety of topic connected with our national history, character, and prospects, and combining in an eminent degree the peculiar charm of popular oratory with the substantial merits of thought and style. His public life began in 1824, when he was elected to congress, and he served by successive reelections ten years. During the whole period he was a member of the committee on foreign affairs, and in the 20th congress he was chairman of that committee. He also held a place on all the most important select committees, and in every instance he drew either the majority or minority report. He wrote the minority report of the committee on foreign relations upon the controversy with France in the spring of 1835, and took a leading part in the debate upon the subject. He made two or three reports on the claims of American citizens on foreign powers, for spoiliations committed on our commerce during the French continental system, and continued the discussion in the "North American Review." He always served on the library committee, and generally on that for public buildings. In 1827 he addressed a series of letters to Mr. Canning on the colonial trade. Besides occasional elaborate public addresses, he prepared several articles of high merit for the "North American Review;" among others a paper in the number for October, 1830, in which the South Carolina doctrine of nullification is discussed and controverted. In the autumn of 1834 he declined a renomination to congress, and in 1835 he was elected governor of Massachusetts. He was afterward three times re-elected, holding the office four years, and was defeated in 1839 by a majority of one vote. The election of Gen. Harrison in 1840, with the appointment of Daniel Webster as secretary of state, led to the selection of Mr. Everett as minister plenipotentiary to England. The relations of the United States with England at that time were grave. The controversy touching the northeastern boundary, which for half a century had been a subject of difference, seemed to have reached a point beyond which

an amicable adjustment was hopeless. The recent burning of the Caroline and the arrest of McLeod had inflamed the public mind in both countries. The case of the Creole, and questions connected with Oregon and Texas, were also elements of irritation. American vessels had been seized and detained by British cruisers on the coast of Africa. Though the settlement of the northeastern boundary and of the Oregon question was transferred to Washington by the appointment on the part of England of Lord Ashburton as special ambassador, yet many important questions were left to Mr. Everett's judgment, unfettered by special instructions. Among the most important was that involving the construction of the first article of the convention between the two countries on the subject of the fisheries. He secured for American fishermen the long disputed right to take fish in the bay of Fundy, and procured the release from the penal colony of Van Diemen's Land of 60 or 70 American citizens convicted of participation in the Canadian rebellion. In the spring of 1843 he was appointed commissioner to China, with a view to establish commercial relations with that country, but he was compelled to decline. Immediately upon his return to the United States in the autumn of 1845, he was chosen president of Harvard university. He entered upon the duties of this new trust with characteristic energy and enthusiasm, but ill health compelled him to resign the post at the end of three years. He afterward prepared a collected edition of his orations and speeches (2 vols. 8vo, 1850). He also superintended the publication of the new edition of the works of Webster, at his special request, and prepared an elaborate memoir, which was prefixed to the first volume. Upon the death of that statesman, in October, 1852, Everett was appointed secretary of state, and held the office during the last four months of President Fillmore's administration. During his brief term of office he adjusted the perplexing affairs of the Crescent City steamer and the Lobos islands, prosecuted with energy the difficult negotiations pertaining to the fisheries, concluded an international copyright convention with Great Britain and a consular convention with France, reviewed the whole subject of Central American affairs in their relations to the government of the United States and Great Britain, and induced congress to establish a mission of the first class to Central America. A prominent question during his administration of the department of state was the joint proposition of Great Britain and France to enter with the United States into a tripartite convention, guaranteeing to Spain in perpetuity the exclusive possession of Cuba. This proposition was declined by the United States, in a diplomatic note drawn up by Mr. Everett. In 1853 he prepared an address for the annual meeting of the American colonization society in Washington, in exposition and

defence of the objects of that association. Before leaving the department of state he was elected by the legislature of Massachusetts to the senate of the United States. He took his seat in the special executive session in March, 1853, and made an able and elaborate speech on the Central American question. In the summer and autumn of 1853, besides an address before the New York historical society on colonization and emigration, and a reply to the protest of Lord John Russell against the doctrines asserted by our government in the note declining the tripartite convention, he spoke more than once in opposition to the proposed new constitution in Massachusetts. The 33d congress was signalized by the introduction of the bill for the repeal of the Missouri compromise, commonly called the Kansas-Nebraska bill. Mr. Everett delivered a speech against the bill, Feb. 8, 1854, characterized by his usual moderate and conservative views, as well as by good taste and good temper. His health, under the pressure of official toil and excitement, now broke down, and in the following May, under the advice of his physician, he resigned his seat. A few months of rest and quiet restored him; and now there began a new phase in his life, and the opening of a new and peculiar sphere of action. In the year 1853 the project of purchasing Mount Vernon by private subscription was first started by Miss Ann Pamela Cunningham, in an address to the women of the United States, under the signature of "A Southern Matron." The proposal was favorably received, and associations of ladies began to be formed in several of the states for the purpose of collecting funds. Mr. Everett had already prepared for the "Encyclopædia Britannica" a life of Washington, afterward separately printed (12mo, New York, 1860); and having been applied to by the mercantile library association of Boston to deliver a lecture during their course of 1855-'6, he proposed that the association should celebrate the next anniversary of the birthday of Washington, and offered to prepare for that occasion a discourse upon his character, the proceeds to be applied to some commemorative purpose. The offer was accepted; and on Feb. 22, 1856, he pronounced his oration on Washington for the first time, before an immense audience at the music hall in Boston. It was immediately repeated at New York, New Haven, and Baltimore, and the proceeds were applied to various objects. It was delivered for the first time for the benefit of the Mount Vernon fund at Richmond, Va., on March 19, 1856; and subsequently it was repeated in different towns and cities nearly 150 times, always, except in a few instances, for the benefit of the Mount Vernon fund. In 1858 he entered into an engagement with Robert Bonner, editor and proprietor of the "New York Ledger," to furnish

an article weekly for that paper for one year in consideration of \$10,000 to be paid in advance to the Mount Vernon fund. These articles were republished as "The Mount Vernon Papers" (12mo, New York, 1861). The entire amount raised by Mr. Everett, who gave also his time and expenses freely, exceeded \$100,000. On Dec. 22, 1857, he delivered in Boston an address on charity and charitable associations for the benefit of the Boston provident association, which was repeated in different parts of the country 15 times, with an aggregate net receipt, for the benefit of various charitable associations, of about \$13,500. On Jan. 17, 1859, he delivered an address in Boston on the "Early Days of Franklin," at the invitation of the association of the Franklin medallists of that city, which was repeated five times, yielding about \$4,000 for the benefit of various charitable and public associations. On Dec. 7, 1858, he pronounced a eulogy on Thomas Dowse, before the Dowse institute, at Cambridge, Mass., which was afterward repeated before the Massachusetts historical society. In 1860 he was nominated as vice president, with John Bell of Tennessee as president, on a "union" ticket, which received 590,681 votes in a popular vote of 4,662,170. On the outbreak of the civil war in 1861 Mr. Everett made several patriotic speeches in the principal cities of the north. At the consecration of the national cemetery at Gettysburg, Pa., Nov. 19, 1863, he delivered the address, afterward published (8vo, Boston, 1864). In the presidential election of 1864 his name was at the head of the Massachusetts ticket as an elector at large, and his vote in the electoral college for Lincoln and Johnson was the closing act of his political career. His last appearance in public was on Jan. 9, 1865, when he made an address in Faneuil hall, Boston, in aid of sending provisions to the suffering people of Savannah. He died on the following Sunday. By direction of President Lincoln, the several executive departments caused appropriate honors to be paid to his memory at home and abroad, and he was the subject of eulogies in public meetings in the leading cities of the Union, several of which were published, including a "Memorial from the City of Boston" and "Proceedings of the Thursday Evening Club [Boston] on the Occasion of the Death of Everett." Besides his addresses, reports, reviews, and other works above enumerated, Everett wrote "The Dirge of Alaric the Visigoth," "Santa Croce," and other poems, and a life of Gen. Stark in Sparks's "American Biography." A collection of his principal public efforts has been published ("Orations and Speeches on Various Occasions," 4 vols. 8vo, Boston, 1869). A statue of Everett by Ball has been placed in the Boston public library, and one by Story in the public garden.

SUPPLEMENT TO VOLUME VI.

DETAILLE

DETAILLE, Jean Baptiste Édouard, a French painter, born in Paris in 1848. He was a pupil of Meissonier. In 1868 he exhibited his "Halt of Infantry," which received much commendation, and the next year his "Repose during the Drill—Camp at St. Maur," won him a decided reputation. During the Franco-German war he was secretary to Gen. Appert, and did good service in making plans of the environs of Paris, sketches showing the positions of the enemy, &c. Since the war his brush has been very prolific in the reproduction of its scenes. In 1873 he exhibited "The Retreat," and received a decoration as a chevalier of the legion of honor. Among the best known of his pictures are "The Passing Regiment," exhibited in December, 1874, and afterward bought for the Corcoran gallery at Washington, which also owns his water-color, "French Cuirassiers bringing in Bavarian Prisoners;" "Saluting the Wounded," first shown in 1877, and now owned by Mr. Samuel Hawk of New York; and "A Reconnoitre," also first exhibited in 1877.

DIÁZ DE LA PEÑA, Virgile Nareisse, a French painter, born in Bordeaux about 1809, died at Mentone, Nov. 18, 1876. He was left an orphan at an early age, in extreme poverty, and lost a leg from the bite of an insect. Being apprenticed as shop boy to a manufacturer of porcelain, he attempted to imitate the decorations, and his master observing this promoted him to his atelier. But after a time they quarrelled, and Díaz, under every possible discouragement, attempted to get his living by painting. His first picture, "The Descent of the Gypsies," remained so long unsold that the dealer, to whom he was indebted for the materials, told him to take it away. At the last moment it was seen and appreciated by a purchaser, who paid 1,500 francs for it, instead of the 500 that had been asked. This picture is considered a *chef d'œuvre*. Díaz attempted

DOBSON

genre subjects with little success, but finally devoted himself to landscapes, which gave him his reputation. He began to exhibit in 1831. He travelled in the East in 1856-'9. The faulty drawing with which he was reproached at first he corrected in the paintings exhibited between 1850 and 1860; but the artistic qualities of his best work are entirely effaced in his later pictures, which were turned out rapidly for the sake of pecuniary gain. His most successful pictures include "A Road in the Forest," "A Pack of Hounds in the Forest of Fontainebleau," "The Smyrniotes," "A Storm," "Galatea," "The Education of Love," and three views in the forest of Fontainebleau.

DICKINSON, Daniel Stevens, an American lawyer, born in Goshen, Conn., Sept. 11, 1800, died in Binghamton, N. Y., April 12, 1866. While he was a boy the family removed to a farm in the Chenango valley, N. Y., on which he worked for several years. He became interested in politics, studied law, and in 1831 settled in Binghamton. He was elected to the state senate in 1836, and lieutenant governor in 1842, and was a United States senator from December, 1844, till March, 1851, being chairman of the finance committee. In December, 1847, he introduced in the senate two resolutions which are believed to have been the first expression of the afterward famous doctrine of "popular sovereignty." On the election of President Pierce, Mr. Dickinson, who had received some ballots in the nominating convention, was pressed for the secretaryship of state; but that office was given to his rival, Governor Marcy, and Mr. Dickinson then retired from politics. Up to the breaking out of the civil war he was a pro-slavery democrat, but during the conflict he was known as a war democrat. His "Life and Works" (2 vols.), by his brother, J. R. Dickinson, appeared in 1867.

DOBSON, Austin, an English poet, born in 1840. In 1858 he was appointed to a govern-

ment clerkship in London, which he still holds (1880). He began to write verses at the age of 25, and by his frequent contributions to periodical literature soon became known as a graceful writer of *vers de société*, which for delicate satire, frequently blended with pathos, had not been equalled by anybody since Præd. He has published in book form "Vignettes in Rhyme" (London, 1874) and "Proverbs in Porcelain" (1877). A selection from these two volumes, made by the author, appeared in New York in 1880, under the title "Vignettes in Rhyme, and other Poems," with an introduction by Edmund C. Stedman.

DODGE, Mary Abigail, an American authoress, born in Hamilton, Mass., about 1838. She was for several years instructor in physical science at the high school of Hartford, Conn., was afterward a governess in Washington, D. C., and early became a contributor to the periodical press. Under the *nom de plume* of "Gail Hamilton," made up of the last syllable of her Christian name and the name of her birth-place, she has published the following books: "Country Living and Country Thinking" (1862); "Gala Days" (1863); "A New Atmosphere" (1864); "Stumbling Blocks" (1865); "Wool Gathering" and "Summer Rest" (1866); "Skirmishes and Sketches" (1867); "Woman's Wrongs, a Counter-irritant" (1868); "Red-Letter Days" (1869); "A Battle of the Books" (1870); "Little Folk Life" (1871); "The Child World" (1872); "Twelve Miles from a Lemon" (1873); "Nursery Noonings" (1874); "First Love is Best" (1875); and "What think ye of Christ?" (1876). Since 1876 she has resided in Washington.

DUPRÉ, Jules, a French painter, born at Nantes in 1812. He studied for a designer in his father's porcelain manufactory, but afterward adopted oil painting as a profession, and in 1831 exhibited five landscapes. Since then, though constantly at work, he has exhibited but little. His pictures, which are noted for color, vigorous drawing, and strong atmospheric effects, include "Animals crossing a Bridge in Berry," "The Forest of Compiègne," "A Sheepfold in Berry," "The Return of the Flock," "The Sluice," "The Fisherman," and "Environs of Southampton."

DURAND, Alice (FLEURY), a French novelist, born Oct. 12, 1842. She is a daughter of Jean Fleury, who has been for many years professor of French in the university of St. Petersburg. She was thoroughly educated, and at the age of 15, when she accompanied her father to Russia, was conversant with Latin, English, and Italian. She takes her *nom de plume* of "Henry Gréville" from a hamlet in Normandy which was the home of her ancestors. Her novels are especially valuable for their pictures of northern life and manners. She has published the following, most of which have been translated into English: *Dosta, L'Expiation de Saveli*, and *La Princesse Oghevo* (1876); *A travers champs, Autour d'un phare*,

Suzanne Normis, Les Koumiassine (translated under the title "Pretty Little Countess Zina"), *Pierrot ermite* (a comedy in verse), *La maison de Maurèze* (translated as "Gabrielle"), *Mariet sa fille, Sonia, Les épreuves de Raissa*, and *Nouvelles russes*, five short stories (1877); *Ariadne, Niania* (translated as "Dournof, a Russian Story"), *L'Amie*, and *Bonne Marie* (1878); *Les mariages de Philomène, Un violon russe* (translated as "Markof the Russian Violinist"), and *Lucie Rodey* (1879); and *Croquis* (1880).

EADS, James Buchanan, an American engineer, born in Lawrenceburg, Ind., May 23, 1820. His parents went to St. Louis in 1833, where he has since resided. He left school at the age of 13, and for five years was a clerk in a dry-goods store. In 1839 he was clerk of a Mississippi steamer. All his spare moments were devoted to the study of engineering and its cognate sciences. In 1842 he constructed a diving-bell boat, to recover the cargoes of sunken steamers, and soon afterward he designed larger boats, with novel and powerful machinery, for pumping out the sand and water and lifting the entire hull and cargo. The field of his operations finally embraced the whole river and its principal tributaries, and many valuable steamers were set afloat and restored to usefulness by his methods. In 1845 Mr. Eads erected at St. Louis the first glass works west of the Ohio river. In 1856 he made a proposition to the government to remove the snags and wrecks obstructing the channels of the Mississippi, Missouri, Ohio, and Arkansas rivers, which passed the house of representatives in 1857, but failed for want of time in the senate. In 1861 he was invited by President Lincoln to visit the capital, for consultation as to the practicability of using light-draught iron-clad vessels on the Mississippi and its tributaries. He soon after designed and constructed a powerful squadron of eight steamers, having a speed of nine knots an hour and aggregating 5,000 tons. These were all completed, plated with iron, fully equipped, and ready for their armament of 107 large guns, within 100 days. They were the first iron-clad vessels constructed by the United States, and several of them were employed in the capture of Fort Henry, Feb. 6, 1862, more than a month before the fight of the Merrimack and Monitor. In 1862-'3 he designed and constructed six turreted iron vessels, all heavily plated. The turrets were quite different from those of Erierson and Coles, and the guns were worked entirely by steam. The 11- and 15-inch guns could in this way be loaded and discharged every 45 seconds. This was the first application of steam in manipulating heavy artillery. In 1867-'74 he designed and constructed the famous steel-arched bridge over the Mississippi river at St. Louis. (See *BRIDGE*, vol. iii., page 276.) Its central arch has a clear span of 520

ft., and the side arches are 502 ft. each. Its granite piers all rest upon the bed rock underlying the river deposits. Two of them are much deeper than any others yet built. One of them, weighing 45,000 tons, was sunk to the bed rock, 136 ft. below high-water mark, through 90 ft. of sand and gravel. Another, weighing 40,000 tons, is founded on the rock 130 ft. below high-water mark. Many novel devices were designed by Mr. Eads in the construction of the caissons, and these improvements were adopted in the sinking of the deepest pier of the East river suspension bridge. The arches were built out from the piers until they met at the centre. The half spans near the shores were upheld by huge iron guys passing over temporary towers on the piers and anchored on shore. On the central piers the half spans balanced each other, being built out from the opposite sides of each pier. As a steel or iron column is shortened when a load is put upon it, so the arches of the bridge are shortened by their own weight when resting against their abutments. They had to be designed $2\frac{1}{2}$ in. too long for the space between the abutments, to allow for this initial compression. The arches are composed of four curved ribs formed of an upper and lower line of steel tubes 18 in. in diameter, strongly braced about 12 ft. apart. Each individual tube of the system is about 12 ft. long. The method of erection adopted by the contractors was different from that intended by Mr. Eads, and resulted in leaving the central space between the half arches $2\frac{1}{2}$ in. too short to receive the central tubes; and as the contractors had constructed each tube according to Mr. Eads's designs, they refused to complete the work of erection so far as it related to the insertion of these central tubes, because they were too long for the space. The problem of how to insert them was thus left for Mr. Eads to solve. If the tubes were reduced $2\frac{1}{2}$ in. in length before insertion, the arch would be several inches too low to suit the roadway when the support of the guys was withdrawn. The financial wants of the bridge company required Mr. Eads to visit London just before the first arch was closed; but before leaving he designed a set of tubes for closing it that could be shortened or lengthened at will. This was done by cutting each one of the original tubes in two, and joining the severed parts by an internal iron plug on which was turned a right-and-left screw fitting into threads inside of the tube ends. Several inches of the tube's length were cut out to permit it to be shortened up, so as to enter the space. Pin holes were made through the plug for the insertion of strong levers by which it could be turned. By this method all these enormous arches were closed. There is a popular belief that the insertion of these tubes was accomplished by contracting all of the other tubes constituting each half span by the application of ice. When the time arrived for closing the first or western arch, an effort was made to in-

sert the unaltered central tubes of the eastern one (which were of the same size) into it by contracting the arch with ice. About 60 tons of ice were applied to it; but after several days spent in the experiment, it was abandoned, and the extension tubes designed by Mr. Eads were inserted without difficulty in a few hours. The ice experiment was made in his absence, and without his knowledge. After the extension tubes were inserted and coupled at each end to the others, the plugs were turned to extend them until the arch was of the desired length. The steel which had been cut out of the length of each tube was then replaced by semicircular pieces of the same quality and diameter, enclosing the exposed part of the plug.—The next great work executed by Mr. Eads was the deepening of the mouth of the Mississippi river. During the past 40 years various plans to accomplish this had been tried. In 1872 a commission of seven engineers of the United States army were charged by act of congress with the solution of the problem. They recommended in 1874 the building of a canal through the left bank of the river, near Fort St. Philip, to connect it with Breton bay, by which the bars at the mouth would be avoided. This plan was vigorously opposed by Mr. Eads in several pamphlets, in which he favored an open mouth for the river, and asserted the entire feasibility of deepening the bar of one of the passes by building parallel jetties out into the sea across it, to prevent the river from spreading out as it enters the gulf, thereby losing its velocity and its power to sustain the sedimentary matter with which its waters are heavily charged. Mr. Eads was strongly opposed by the chief of engineers of the United States army, and by nearly all the members of the corps. But he challenged the attention of congress and the country by a proposition to undertake the deepening of the mouth of the Southwest pass by jetties to the depth of 30 ft., at the sole risk of himself and his associates, without demanding any pay whatever until after 20 ft. should have been secured, the normal depth on that bar being about 14 ft. At the time this offer was pending the house of representatives actually passed a bill to appropriate \$8,000,000 for the construction of the canal. But the offer of Mr. Eads was so manifestly to the interest of the government, and his reputation as an engineer had been so well established, that the senate refused to concur, and referred the question to another commission composed of three engineers from the army, one from the coast survey, and three civil engineers. Nine months afterward six members of this commission reported in favor of trying the jetty system at the mouth of the smallest of the three passes (the South pass); but the arguments of Mr. Eads in favor of the larger pass prevailed, and the house of representatives passed the jetty bill by an almost unanimous vote for the larger pass. This action, however, was not concurred in by the senate, and the bill was finally

amended and made to apply to the little pass. Instead of a single bar with 14 ft. depth, Mr. Eads was now compelled to undertake two of them, one in the sea with 8 ft. on it, and one in the river with 14 ft. The sum agreed to be paid for the work was \$5,250,000, which was considerably less than the estimate of the commission. Only \$500,000 was to be paid after the jetties and auxiliary works should have secured a channel 200 ft. wide, and in no part of less depth than 20 ft.; when a channel 22 ft. deep and 200 ft. wide was secured, another half million was to be paid; and similar payments were to be made on obtaining 26 and 28 ft. It was predicted that the bar would re-form in front of the jetties, and the expense of extending and maintaining them was estimated by the commission at \$130,000 a year. This extension and maintenance was undertaken by Mr. Eads for \$30,000 a year less than the estimate; and as a guarantee that it should not cost over \$100,000 a year for 20 years, he consented to allow the government to retain \$1,000,000 of the price of the jetties after it should be earned. To secure the first payment, at least half of the whole work had to be executed; and when 22 ft. was reached, 80 per cent. of it was completed. At this period the terms of the act proved so oppressive that he was compelled to ask congress to modify them. An advance of \$1,000,000 was promptly voted, to enable him to prosecute the work. The bill also provided that a commission of five army engineers should inspect the works and report regarding them and their effects, and also what further measure of relief it would be proper to extend to Mr. Eads. This report was very favorable so far as it related to the permanence of the works and of the channel, and of the deepening of the sea bottom in front of the jetties where a new bar had been predicted; but it advised against any further payments beyond those provided in the jetty act. Congress, however, took a different view of the matter. Being satisfied from the report that 75 or 80 per cent. of the work had been executed, and that it was destined to be entirely successful, a further advance of \$750,000 was voted. On July 8, 1879, the United States inspecting officer at the jetties reported that the maximum depth of 30 ft. had been secured through the jetty channel, and that the least width of the 26-foot channel through the jetties was 200 ft. The remainder of the \$4,250,000 was thereupon paid. Mr. Eads has written essays and delivered addresses in favor of the application of the jetty system of improvement to the Mississippi throughout its alluvial basin. His plan is to correct the wide parts of the river by so contracting the high-water banks at such places as to create a comparative uniformity of width throughout the alluvial district. This, he believes, will produce a uniformity of depth, and secure at least 20 ft. of water from Cairo to the gulf. In 1879 congress authorized the creation of a mixed commission of civil and military engi-

neers, to be called "the Mississippi River Commission," and to be composed of seven members, of whom Mr. Eads was one. It was made the duty of this commission to prepare a plan for the improvement of the navigation of the river, and for the prevention of destructive floods. The commission has recommended the system proposed by Mr. Eads for the river below the mouth of the Ohio. The plan is to make the improvement by means of light and cheap willow dams or screens, erected a few feet high across the places where the width is to be reduced, to encourage the deposit of sediment, and, by gradually raising them through a period of eight or nine years, to build up the shoals and develop with them new and more uniform shore lines. The congressional committee charged with the subject have unanimously reported a bill appropriating \$5,000,000 to begin the work. In addition to giving the channel a low-water depth of 20 ft. to Cairo, it is asserted by Mr. Eads that by this method a district as large as the state of Indiana, constituting the alluvial basin of the river, will be saved from overflow, without the need of levees.—Immediately after the publication of the proceedings of the inter-oceanic canal congress held at Paris in 1879, Mr. Eads published a letter containing a project for a ship railway across the American isthmus, as a substitute for the sea-level canal proposed by that convention. Among other arguments advanced by him in support of this method are: 1. The railway can be built for one quarter of the cost of the canal; 2. It can be built in one quarter of the time; 3. It can transport the ships more rapidly with absolute safety; 4. Its actual cost can be more accurately foretold; 5. The expense of maintaining and operating it will be less than that of the canal; 6. Its capacity can be easily increased to meet the future requirements of ocean transportation; 7. It can be built at many places on the isthmus where a canal is wholly impracticable. Mr. Eads is now (1880) pressing this matter upon the attention of congress.

EDISON, Thomas Alva, an American inventor, born in Milan, Ohio, Feb. 11, 1847. His parents lived in humble circumstances. His mother had been a schoolmistress, and imparted to Thomas, who was one of several children, all the teaching he received. He displayed an unusual appetite for instructive reading. The family removed to Port Huron, Mich., where he passed his childhood and youth, engaging in a self-supporting occupation, as train boy on the Grand Trunk railroad, at the age of 12. He studied qualitative analysis and conducted chemical experiments on the train, and set in type and printed a newspaper in the baggage car where he kept his wares and his retorts. The operations of the telegraph, which he constantly witnessed in the stations along the railroad, awakened his interest, and he improvised rude batteries and attempted to transmit messages between

his father's house and a neighbor's. A station master, whose child he rescued from in front of a coming train at the risk of his life, taught him telegraph operating. As a working operator he wandered for several years over the United States and Canada. He acquired great skill in his profession, but frequently neglected his practical duties for the study of electrical science and experimentation. The germs of some of his later inventions were conceived at this period. In 1864, while at Memphis, he began his experiments in duplex telegraphy. At Boston in 1868 he was recognized as a very competent operator, and drew attention to himself by several minor inventions, such as a telegraphic instrument for private use, with a dial on which an indicator points out the letters and signs, and a chemical note recorder. The failure of a trial of his system of duplex transmission deprived him of the encouragement and confidence which his ingenuity was beginning to awaken in others. Greatly disheartened, he went to New York, where a fortunate chance for the exercise of his inventive genius immediately secured an assured position and a large pecuniary reward. The indicator of the gold and stock company broke down at a critical moment, and as the regular mechanic was not within call, Edison volunteered to repair it. After this he exhibited to the managers of the company a device which had suggested itself immediately as he was setting the indicator in order: it was the printing telegraph for gold and stock quotations. The great practical utility of this invention brought him into very prominent notice. The gold and stock company and the western union company retained him at a high salary to give them the refusal of his future telegraphic inventions. He was thenceforth allowed to pursue untrammelled his inventive bent, and provided with ample means for experiments. He established a large workshop at Newark for the manufacture of the printing receivers for stock quotations, while concentrating his own attention on the important improvements in telegraphy which he now rapidly developed. In 1876, in order to give up his whole mind to new inventions, he disposed of his machinery, and removed to Menlo Park, N. J., a small unfrequented village at an hour's distance from New York, on the Pennsylvania railroad. The large sums which his inventions brought him he expended in extensive experiments, employing assistants, and fitting up large workshops and laboratories at Menlo Park, in which he had soon invested several hundred thousand dollars.—Of Edison's numerous inventions, for which he had already taken out 150 patents in 1878, the most important ones, out of which the others grew and about which they naturally group themselves, are the system of duplex telegraphy, which he developed into quadruplex and sextuplex transmission; the carbon telephone and its modifications; the microtasmeter; the microphone, the aërophone,

and the megaphone; the phonometer, the principle of which was suggested to him by his experiments with telephonic receivers, and which he followed with new acoustic devices; and the electric light with a carbon burner in a vacuum. The electric pen and a great number of other minor independent contrivances attest the remarkable fertility of his inventive faculty not less decidedly than his more famous inventions. The electric pen is a thin needle with which punctures are made with incalculable rapidity in a sheet of paper as the pen is moved along to form letters; this sheet is then used as a stencil, from which any number of copies can be taken of letters or drawings by passing ink through the minute perforations to a sheet of paper underneath. The phonograph is an invention of great simplicity, which produces effects that were regarded at first with incredulous wonder. (See PHONOGRAPH.) The megaphone is an arrangement with trumpet funnels, with which speech can be conveyed and heard through the air at a distance of several miles. (See MEGAPHONE, in supplement.) The aërophone is a design for magnifying the sounds of the voice two or three hundred times by the aid of a steam blast, and is to be applied to signalling and communicating with ships out at sea. Edison's inventions in chemical electric printing enable the sender of a telegram to produce the message at the other end of the wire in his own handwriting. By his microtasmeter infinitesimal variations of pressure are noted, so that the smallest changes in temperature can be recorded. (See MICROTASIMETER, in supplement.) The phonometer is an apparatus for measuring the force of the sound waves produced by the human voice.—The perfection of multiplex telegraphy is perhaps the greatest of Edison's achievements. Other electricians had experimented upon the simultaneous transmission of two or more messages by the same wire. The method invented by Stark in 1855, and improved by Krämer, Bernstein, Schreder, and other German electricians, consisted in employing a number of relays, and was only practicable on very short lines. Proceeding by entirely original methods, Edison confined himself to two relays, avoiding by an ingenious device the obliteration of signals caused by changing the polarity of the current. By the contrivance of the electro-motograph, the most sensitive recording instrument ever invented, Edison gave to the world the duplex system of telegraphy in a working shape, and rendered quadruplex and sextuplex transmission possible. In his carbon telephone, the variation in the current is produced by the variable resistance of a solid conductor subjected to pressure, rendering the inflections and variations in the intensity of the vocal sounds to be transmitted more faithfully than any of the other telephones. Edison's electric light does not involve new principles, but rather a return to the earliest proposed method of electric illumina-

tion. He believed that the process of lighting by the voltaic arc, in which great results had been already achieved, would never answer for general illumination. In reviving the long-abandoned process of lighting by incandescence, he entered upon a path beset with difficulties, in which he had nothing to guide him but the failures of his predecessors. None of his inventions cost him more study and labor than he expended in overcoming the slight-appearing hindrances in the way of a practicable electric light. After entirely perfecting a device for a lamp with a platinum burner, and setting miners on the search for the rare metal he designed to use, who discovered numerous indications of its presence in the gold and silver regions, he happened upon a form of carbon of sufficient homogeneity to give a light as steady as and much more brilliant than the incandescent iridio-platinum. He had already been obliged to employ for his platinum burner the device (which Lodyguine and others had used with incandescent carbon burners) of enclosing it in an exhausted glass globe. A carbon burner is practically indestructible under incandescence in a vacuum, provided the exhaustion is sufficiently perfect. The difficulty of producing a high vacuum was one of the chief obstacles in the way of former experimenters with incandescent carbon. By combining the action of a mercury air pump with the intensest heat produced by electricity, he had succeeded in readily producing an attenuation of the air remaining in his glass globes, after hermetically sealing them, such as is rarely attained by scientific experimenters, exceeding but little the millionth of an atmosphere. By carbonizing cardboard (for which bamboo fibre was afterward substituted) and then subjecting it to powerful electric currents in the vacuum, he discovered that it became fused into a tough material with a glassy surface, and completely even and homogeneous in texture. Edison gave a public trial of his process in December, 1879. There still remained a difficulty to be met, but one scarcely so formidable as many which he had already vanquished: the glass globes were subject to crack in the neighborhood of the platinum wires which were fused into them, thus destroying the vacuum.—In his investigations for an increased supply of platinum, Edison found that it was confined to a few of the California gold mines, and remained in the tailings or refuse of the crushed ore of these mines, after the gold had been extracted as thoroughly as possible by the ordinary processes with water and quicksilver. While experimenting on specimens of tailings, with a view of devising an economical mode of extracting the platinum, he was surprised at the large quantity of gold still remaining in the refuse of the ore. He immediately turned his attention to the question of the exploitation of this source of wealth, and invented a process by which the ore exhausted by the old operation yields a greater quantity of the precious

metal than has been already extracted. By Edison's process, which has been put in practice by the "Edison Ore-milling Company," he is said to have obtained from the black sand of the lava beds gold at the rate of \$80 a ton, from the incrustations of the flumes as much as \$750 a ton, and from the tailings of one mine—the Powers claim—no less than \$1,400 a ton. The working up of black sand is facilitated by the employment of magnets to separate the black particles, containing iron, from the auriferous grains. The method—or methods, since the process differs for different ores—by which Edison has succeeded so much better than the many inventors who have given their minds to the same problem of working over the tailings to recover the waste gold, which amounts to a far greater quantity in most ores than was ever supposed, consists in chemical combinations aided by electrochemical action.

EDMUNDS, George Franklin, an American statesman, born in Richmond, Vt., Feb. 1, 1828. He was educated in the common schools and under a private tutor. He was admitted to the bar in 1849, devoted himself exclusively to the practice of his profession, and in 1851 removed to Burlington. In 1854-'5, and in 1857-'9, he was a member of the lower house of the Vermont legislature, of which he was for three years the speaker. He was elected to the state senate in 1860 and 1862, and was president *pro tempore* of that body. On the breaking out of the civil war he was a member of the state convention which met to form a coalition between the republicans and war democrats, and drew up the resolutions which that convention adopted. On the death of United States Senator Solomon Foot, in March, 1866, the governor of Vermont appointed Mr. Edmunds to succeed him, and he took his seat the next month. The legislature subsequently elected him to fill the unexpired term, and he was reelected for the terms ending in 1875 and 1881. He has served on the committees on commerce, public lands, appropriations, pensions, retrenchment, private land claims, the library, and the judiciary; being chairman of the judiciary committee during the 42d, 43d, 44th, and 45th congresses. He was chairman of the senate committee which, in concert with a similar committee of the house of representatives, prepared the electoral commission bill of 1877, earnestly supported that measure in the senate, and was a member of the commission. As a senator, Mr. Edmunds is chiefly remarkable for his legal knowledge, his unsurpassed parliamentary skill, and his close attention to legislative detail.

ELECTORAL COMMISSION, a tribunal created by a special act of congress for the purpose of adjudicating upon the questions connected with the counting of the electoral vote in the disputed presidential election of 1876. In the November elections of that year, on the ticket of the democratic party, whose candidates were Samuel J. Tilden and Thomas A. Hendricks,

184 electors had been chosen beyond dispute; the republican nominees, Rutherford B. Hayes and William A. Wheeler, had 172 undisputed votes in their favor in the electoral college; the votes of Florida and Louisiana, the first state being represented in the college by four electors, the second by eight, and one of the electoral votes of Oregon, were in dispute on different grounds between the two parties. Returns of the electoral votes of these three states had been forwarded to the president of the United States senate, audited and certified by the regularly appointed state canvassing and returning officers, declaring the ballots of the electors on the Hayes ticket; to these the certificates of the governors of the states, required by an act of congress, were appended, except in the case of Oregon. Conflicting returns, less regular in form, had also been handed in containing the votes of the Tilden electors. The authorized usage, which had been followed in the preceding presidential elections, was for the president of the senate to open the sealed packages containing the certified returns of the electoral ballot before both houses of congress, assembled in joint session, and to count and declare the vote of the college of electors. The president of the senate, supported by the republican legislators, with few exceptions, insisted that the authority to decide upon who were the properly constituted electors rested in him, and that he was empowered by the laws to count the regularly attested ballots and pronounce the candidate who had received the majority vote the president elect. This doctrine was vehemently opposed by the democrats, and its soundness was doubted by some republicans; but even the former feared a resort to extra-legal and violent measures. The general feeling was, that the jurisdiction in the controverted legal and constitutional questions arising out of the election, as far at least as the determination of the duly authorized electoral votes was concerned, resided in both houses of congress conjointly. There was, however, no hope of an adjustment of the matter by the concurrent action of the two houses, as the senate was controlled by a republican majority, while in the house the majority was largely democratic. As a compromise, it was proposed to intrust the decision to a commission to be composed of representatives, senators, and members of the supreme court, in equal numbers. Mr. Edmunds, of the senate, brought forward a bill constituting such an electoral commission, to consist of five members to be chosen from its body by the house of representatives, five senators to be elected by the senate, four judges of the supreme court from certain designated districts in widely separated parts of the Union, and a fifth to be chosen by these four out of the remaining five justices of the supreme court. The electoral bill delegated to the commission all the jurisdiction possessed by congress in determining which were the true and lawful electoral votes in the contested states, without

defining the exact scope of that jurisdiction. After much amendment and revision in both houses, the bill became a law in the latter part of January, 1877. The commissioners appointed by the senate were Senators George F. Edmunds, Oliver P. Morton, Frederick T. Frelinghuysen, Allen G. Thurman, and Thomas F. Bayard; those elected from the house were Henry B. Payne, Eppa Hunton, Josiah G. Abbot, George F. Hoar, and James A. Garfield. The justices sitting on the commission in virtue of the provisions of the act were Judges Nathan Clifford, Samuel J. Miller, Stephen J. Field, and W. Strong. They unanimously chose Judge Joseph P. Bradley to be their colleague. In accordance with the act, the senior justice, Nathan Clifford, presided over the deliberations of the commission. The counsel who pleaded the cause of the democratic electors were Charles O'Connor of New York, Judge J. S. Black of Pennsylvania, Judge Trumbull of Illinois, and Messrs. Merrick of Washington and Green of New Jersey; the republican case was presented by William M. Evarts of New York, Stanley Matthews of Ohio, Judge Shellabarger, and Mr. Stoughton. The commission assembled on Jan. 31, 1877, prepared to entertain the questions submitted to it by congress, which began the count of the electoral votes on the following day. The objections raised against accepting the regularly certified vote of Florida, giving the state to Hayes, were based upon the action of the canvassing board in rejecting the votes of certain districts on the ground of fraud; this, it was held, exceeded their statutory powers, which were simply ministerial. A minor objection was offered, but not pressed, against one of the electors, who was alleged to have been disqualified by the concurrent tenure of a federal office. It was claimed that a judgment rendered against the Hayes electors by the Florida supreme court ought to guide the commission in its rulings in this case. In Louisiana very unusual powers were conferred by statute upon the returning board. It was empowered to revise the reports of supervisors of elections in cases where a formal protest had reached it from citizens in the respective parishes, and, upon evidence that the election in any parish had not been fair and free, by reason of fraud, violence, or intimidation, to reject the whole or a portion of the votes returned from that parish, and disregard them in counting up the vote of the state. These judicial powers had been exercised with much license by the returning officers in counting the presidential vote. According to the records sent them from the parishes, the state had been carried for the Tilden electors by a considerable majority. The numerous vote of the parishes of East and West Feliciana, in which the colored inhabitants are largely in the majority, and where the republican voters had refrained from the ballot entirely, was thrown out altogether on the ground of intimidation. In the cases of other parishes

the returns had been rejected or modified on the ground of fraud. It appeared that this power of revision had been exercised in certain instances where no formal complaint, such as is required by the statute, had been presented to the board. The counsel for Mr. Tilden argued that the failure to observe the statute in the latter cases rendered the count made by the returning board and forwarded to congress of no legal effect. They furthermore claimed that the statute conferring judicial and revisory powers upon the returning board was passed in violation of the Louisiana state constitution, and that it was also repugnant to the constitution of the United States. In Oregon the republicans had carried the state, but the governor had substituted one of the Tilden electors for a republican elector who was ineligible; and this democratic elector, with two associates chosen by him, had sent to congress a report giving one vote to Tilden and two votes to Hayes, with the governor's signature appended, which the republican return lacked. The counsel in their plea alleged against the acceptance of the republican list the ineligibility of the one elector, and the formal defect of the absence of the governor's certificate; while the republicans insisted that the defective title of that elector had been made good by his resignation of the federal office which had made him ineligible, and his subsequent legal election by his associate electors on the successful ticket. The returns from South Carolina were also objected to, on the ground that the presence of federal troops stationed in that state amounted to a menace which intimidated voters. The returns from Florida and Louisiana were declared by the counsel for the objectors to be tainted with fraud, besides their illegality or unconstitutionality, and therefore void, in accordance with the maxim of the common law that fraud vitiates every claim connected with or flowing out of the fraudulent transaction. The question upon which the decision hinged was whether the commission was bound and authorized to investigate and pass judgment upon the issue of the popular vote in the contested states, and upon the validity of the official lists as representing the actual vote—*i. e.*, to go behind the face of the returns. This question had been opened in the debates over the electoral bill, but congress had refrained from a decision in either sense, and left the question of jurisdiction to be determined by the tribunal itself. The act had imposed upon the commission the duty of considering the objections to the conflicting returns, "with the same powers, if any, now possessed by the two houses acting separately or together," and upon the evidence laid before it of deciding "whether any and what votes from such [disputed] state are the votes provided for by the constitution of the United States, and how many and what persons were duly appointed electors in such state." On the one side it was

argued that the commission must entertain and decide the questions brought before it from evidence as to the actual result of the popular vote, since by the popular vote alone were the electors duly appointed. On the other side it was urged that the constitution denied to congress, and consequently to the commission, the right to inquire into the methods and results of popular elections, by conferring upon the state legislatures the whole power of determining the mode of election and the bestowal of the franchise in the respective states; that congress was consequently bound to accept the duly accredited returns made to it by the state officials properly constituted for this purpose, and was solely concerned with counting the electoral votes delivered to it by the states through their own appointed organs. With complete uniformity in all the divisions, the republican commissioners, Miller, Strong, Edmunds, Morton, Frelinghuysen, Garfield, and Hoar, and with them Bradley, upheld the doctrine that congress was bound to accept the official returns of the state authorities, carrying every decision by a majority of one against the opposing votes of the democratic commissioners, Clifford, Field, Bayard, Thurman, Abbot, Hunton, and Payne. The count of the electoral vote, prescribed by the electoral bill, before congress in joint session, was concluded March 2; and two days after, on the regular day, by virtue of the findings of the electoral commission, Mr. Hayes was inaugurated as president of the United States.

ELECTRIC LIGHT. The subject of electric lighting has recently acquired new and unusual interest, and many ingenious appliances, designed either to overcome existing difficulties in the way of practical results, or to improve the methods already employed, have been brought to the attention of the public. Lighting by electricity is accomplished in several different ways; but all the methods depend on the principle of the resistance encountered by an electric current in passing through its circuit. When such a current in a metal wire or other conductor meets with resistance to its passage, the electricity is directly converted into heat. If a thin wire is placed in the circuit, the temperature of the wire rises, and the amount of heat thus generated is exactly proportional to the electric resistance of the wire. This resistance depends among other things on the nature of the metal; those metals which are good conductors, such as silver, offering much less resistance than those which are bad conductors, such as platinum. If a chain formed of alternate links of silver and platinum have an electric current of suitable intensity sent through it, the platinum links will glow vividly, while the links of silver will remain dark and comparatively cool. From its low electric conductivity, or, what amounts to the same thing, from its high resistance, platinum is peculiarly fitted for exhibiting incandescence. Another condition influencing the amount of

resistance is the size or thickness of the conductor. Reduce the thickness, and the resistance is immediately increased, with a corresponding increase in the production of heat, the latter being also closely connected with the strength of the current. Hence a powerful current sent through a small platinum wire immediately renders it incandescent, and many attempts have been made to utilize this metal for the production of the electric light. Thus far these have been attended with little success, for the reason that if the current driven through the thin wire or strip of platinum is sufficiently powerful the heat rises to such an intensity that the metal is fused, melting down like a mass of wax in the flame of a candle. When this occurs, the electric circuit is of course immediately broken, and the current consequently interrupted. To avoid such a result, some conducting substance capable of becoming incandescent, but that would not fuse at the highest heat, was required. Carbon answers these conditions, and has accordingly been used in one form or another for the production of the electric light ever since the famous experiments of Davy, nearly 70 years ago. In this mode of producing the electric light the continuity of the circuit remains unbroken, the light being obtained by connecting the conducting wires with some substance like platinum or carbon, so shaped as to offer increased resistance to the passage of the current, by which it is thrown into a state of incandescence. But the various means of obtaining light by the incandescence of a resisting medium—be that medium a metal of low conducting power like platinum, or a thin rod of carbon—are materially different from those employed in producing what is specially known as *the electric light*. This light was first obtained by Sir Humphry Davy in 1813, while experimenting with the great battery of the royal institution in London. This battery consisted of 2,000 zinc and copper couples, exposing an aggregate surface of 128,000 square inches. Davy found that when the current from this pile was passed between two pointed pieces of wood charcoal attached to conducting wires, a light next in brilliancy to sunlight was produced. He also found that this intense light was accompanied by intense heat. Many substances which had previously been regarded as infusible were melted and even volatilized when placed in the luminous focus. Like effects were produced in a vessel exhausted of air or in an atmosphere of nitrogen or carbonic acid gas. Hence it was concluded that the light did not proceed from ordinary combustion. In this as in the former case the light and heat are the result of the resistance met with by the electric current in its passage through the circuit, the difference being that here the resistance is due to a gap in the circuit which the current is forced to bridge. The interval between the charcoal points offers a great obstacle to the passage of the current,

and it is to the gathering up of the force necessary to burst across this interval that the intense heat and light are due. The smallest space of air is usually sufficient to stop the current; but when the carbon points are first brought together and then separated, it is seen that glowing particles of carbon are constantly springing across the gap from pole to pole. Although this takes place in both directions, the prevailing course is from the positive to the negative electrode. In fact, the positive carbon becomes much more highly heated and wears away much more rapidly than does the negative carbon. These solid particles of incandescent carbon are believed to form a sort of conducting chain between the poles, by the aid of which the current passes. It will therefore be seen that this mode of illumination is, after all, like the other, largely due to incandescence. In order to produce this form of electric light, the carbon poles are first brought together and then separated to a little distance, the space across which the light can leap depending on the power of the current. With the battery before alluded to, Davy was able to obtain a current that in the open air would leap a space of 4 in. between the carbon points, and this was lengthened to 7 in. in a vacuum. The luminous portion of the circuit, which forms a bridge between the two solid poles, is usually a little bent, and hence receives the name of the voltaic arc. The color and shape of this luminous are depend on the nature of the poles, but the light comes chiefly from the glowing carbon points, while a pale-blue flame fills the intermediate space.—As we have seen, the form of carbon used by Davy in his original experiments was wood charcoal, but this wasted away so rapidly that it was of no practical use outside the laboratory and the lecture room. In fact, the electric light amounted to little more than a brilliant experiment until 30 years later, when Foucault proposed to substitute for charcoal the variety of carbon deposited in the interior of gas retorts, and known as gas carbon. This is produced by the decomposition of dense gaseous hydrocarbons, at the high temperature at which the distillation of coal is carried on. The gas carbon has a laminated structure, is very hard and solid, and when sawed into rods or pencils is used with advantage in producing the electric light, since it is vastly more durable than the softer forms of carbon, such as wood charcoal. But gas carbon also has its disadvantages, being rarely pure or of uniform texture—conditions that produce a fluctuating and unsteady light and the formation of sparks; the pencils are also liable to split, and portions become detached under the action of the high heat to which they are subjected. To obtain perfectly homogeneous carbons, various artificial processes have been suggested, among which two, both of them French inventions, have yielded very fair results. In one of these processes, devised by M. Carré, a composition consisting of powdered coke, cal-

cined lampblack, and a sirup made of 12 parts of gum and 30 of cane sugar, is employed. This mixture is thoroughly ground together, water added to form a paste, and the mass then pressed through a die plate by which the proper form is given to the carbons. These are afterward packed in crucibles and subjected to a high temperature for several hours, then removed and soaked in a boiling sirup to fill up the pores, and after draining subjected to another baking. These operations are repeated with various modifications until the carbons have acquired the necessary hardness and solidity. In use they are said to be much superior to the ordinary retort carbons; but they have their defects, nevertheless, the most serious of which are a rapid wasting away, and considerable irregularity of luminous effect. The carbons that so far have given most satisfaction are made after a process invented by M. Gaudoin. The first step in this process has for its object the production of a pure form of carbon, which the inventor obtains by the decomposition in closed vessels of the dried pitches, fats, tars, resins, bitumens, essences, oils, and other organic matter. The carbon thus derived is pulverized as finely as possible, and then agglomerated, either alone or with a certain quantity of lampblack, by means of the carbides of hydrogen obtained as secondary products. The material is then moulded under heavy pressure into the form required for use. These carbons are consumed more rapidly than the retort carbons, but less so than those produced by the Carré process; and in all other important respects, such as the power, brilliancy, and steadiness of the light, absence of sparks, tenacity, and even consumption of the pencils, they leave little to be desired.—As the carbons, whatever their make or however well they are protected, slowly waste away when the light is in operation, it becomes necessary to move them together at a rate proportioned to the rapidity with which they are consumed. If the light is to be continuous, the distance between the carbon points must be kept constant; and, as the positive carbon is destroyed much faster than the negative carbon, provision must be made for a corresponding increase in its velocity. To maintain this adjustment of the carbon points has always been one of the chief difficulties in the way of electric illumination, and a large number of inventions, some of them simple and others exceedingly complex, have been used with varying degrees of success. The later devices show a marked tendency toward greater simplicity of structure and a corresponding increase in efficiency. The apparatus for carrying the carbons combined with the mechanism required for their continued adjustment is called the electric lamp. It is usually so arranged that the carbons are held in a vertical position, and by means of the regulators the light is kept at a nearly uniform level. One of the earliest forms of such a lamp is shown in fig. 1. It was invented by

M. Foucault, and affords a fair idea of the complexity of the mechanism employed in the electric lamp to regulate the movements of the carbons. In this apparatus there are two systems of automatic wheel work, one for bringing the carbon points together when it is wished to start the light, and the other for separating and maintaining them in the proper relation for the continuation of the light. *L'* is a barrel driven by a spring enclosed within it, and driving several intermediate wheels, which transmit its motion to the fly *o*. *L* is the second barrel, driven by a stronger spring, and driving in like manner the fly *o'*. The racks

FIG. 1.—Foucault's Regulator.

which carry the carbons work with toothed wheels attached to the barrel *L'*, the wheel for the positive carbon having double the diameter of the other, the same as in the Duboseq lamp. The current enters at the binding screw *C*, on the base of the apparatus, traverses the coil of the electro-magnet *E*, and passes through the wheel work to the rack *D* which carries the positive carbon. From the positive carbon it passes through the voltaic arc to the negative carbon, and thence through the support *H* to the binding screw connected with the negative pole of the battery. When the armature *F* descends toward the magnet, the other arm of

the lever *F P* is raised, and this movement is resisted by the spiral spring *R*, which, however, is not attached to the lever in question, but to the end of another lever, pressing on its upper side and movable about the point *X*. The lower side of this lever is curved, so that its point of contact with the first lever changes, giving the spring greater or less leverage, according to the strength of the current. In virtue of this arrangement, the armature, instead of being placed in one or the other of two positions, as in the ordinary form of apparatus, has its position accurately regulated, according to the strength of the current. The anchor *T t* is rigidly connected with the lever *F P*, and follows its oscillations. If the current becomes too weak, the head *t* moves to the right, stops the fly *o'* and releases *o*, which accordingly revolves, and the carbons are moved forward. If the current becomes too strong, *o* is stopped, *o'* is released, and the carbons are drawn back. When the anchor *T t* is exactly vertical, both flies are arrested, and the carbons remain stationary. The curvature of the lever on which the spring acts being very slight, the oscillations of the armature and anchor are small, and very slight changes in the strength of the current and brilliancy of the light are immediately corrected. The Serrin lamp (fig. 2) is a

Fig. 2.—Serrin Regulator.

Fig. 3.—Rapiéff Regulator.

favorite though complicated device, that has been used in both France and England where only a single light is required; and lately some

ingenious improvements have been added to it by M. Lontin. In it the carbons are held vertically one over the other. The upper carbon is made to travel by means of a rack and pinion attached to the bottom of its holder, and driven by a spring which is under the control of an electro-magnet in the base of the lamp. According to the force of the current passing into it from the main current, this electro-magnet attracts or releases an armature, and the effect of this oscillating movement is to cause the lower carbon-holder to rise or fall with the irregularities in the strength of the main current, which is itself producing the voltaic arc. The separation of the carbon points to suit any required length of arc is effected by raising or depressing the upper carbon-holder, by means of a screw placed at the top of its upright, where the horizontal arm is hinged.—A novel form of lamp of still more recent invention, and possessing certain decided advantages, has been devised by a Russian engineer named Rapiéff, and used in the office of the London "Times." In this apparatus (fig. 3) each carbon is as it were split lengthwise, and the halves are placed relatively to each other in the form of a V, approaching each other only at the point of illumination. In proportion as the carbons are consumed, they are caused by an ingenious arrangement of cords and pulleys to approach each other; and thus the voltaic arc is always produced through a constant distance. With rods measuring 20 in. in length and about 6 mm. in diameter, a light may be uninterruptedly maintained for nine or ten hours. In this apparatus the current does not pass through the entire length of the carbon pencils, but enters by means of curved metallic arms at points within 2 in. of the luminous focus; hence the resistance offered to the current is kept constant, whatever may be the length of the carbons. This secures a uniformity of illumination that cannot be obtained in lamps where the current has to pass through the entire length of the carbon pencil, for as this shortens the resistance decreases; hence the intensity of the current, and therefore of the light, rises in proportion as the carbons are consumed. In the ingenious lamps of M. Lontin the resistance is also constant, irrespective of the length of the carbon rods. In another of M. Rapiéff's lamps the two pairs of carbon rods are placed not one above the other, but side by side. The arc is produced at the junction of the four points, and the effect is considerably increased by the presence of a cylinder of lime, which is placed above the light, and contributes by its incandescence to increase the intensity of the light.—In the various forms of electric lamp thus far described, and in many others, the carbon pencils are separated to a certain distance, and across this the voltaic arc is produced. A form of lamp has been lately invented by Mr. Richard Werdermann in which the light is produced while the carbons are in direct contact.

The lamp (fig. 4) is therefore reduced to extreme simplicity of construction. In the ordinary arrangement, in which the two pencils are of equal sectional area, the end of the positive carbon is worn into a crater-like shape, and

FIG. 4.—Werdermann Lamp.

from this pole the greater part of the light is emitted; on the other hand, the negative carbon is formed into a cone, and becomes but slightly luminous. Werdermann found that, by increasing the sectional area of the negative electrode, its consumption is diminished, and if it be sufficiently large it suffers no appreciable loss during the passage of the current. He therefore uses in his lamp two carbons which are extremely unlike each other both in size and shape. The negative carbon C, supported by the bracket B, is a disk, flat on one side and curved on the other, its shape being not unlike that of a bun. The diameter of this disk is about 2 in. and its thickness 1 in. The curved surface of the disk is directed downward, and against this surface the positive carbon *c* is pressed. This carbon is in the form of a thin pointed pencil 3 mm. in diameter. It is held by means of a spring collar in a metallic tube in which it slides vertically up and down. A cord connects the clasp D, at the bottom of the rod, and the balance W, by which the rod is held in contact with the disk. On the passage of the current a very small electric arc is produced, but it is remarkable for steadiness and for purity of color. Round the upper part of the disk is a metallic band A, to which the circuit wire is attached, and the current is thus passed on to the next lamp. With this lamp the electric light may be obtained from an electro-motor of very low power. With a small Gramme machine driven by a 2-horse-power engine, and yielding an electro-motive force equivalent to only about four Daniell's cells, ten of these electric lamps were placed in circuit at once. The light, even with large lamps of 300-candle power, is so soft that

it appears unnecessary to protect it with globes of opal glass.—A lamp, not altogether unlike Werdermann's in principle, has been constructed by M. Reynier. In this arrangement a carbon pencil presses directly against the edge of a circular disk of carbon which revolves in a vertical plane. The pencil forms the positive electrode, and the current enters not far from the pointed extremity in contact with the disk. As the carbon burns away it is urged forward by a simple mechanism, and thus contact is never broken. The residuum, or ash, left by the combustion of the positive carbon is continuously removed by the rotation of the negative disk. It is said that this lamp gives a clear light with only a small electro-motive force, and that several lamps may be operated by the same current.—A novel form of electric lamp, still more simple, has been patented by Mr. W. Wallace, of Ansonia, Conn. Its peculiarity (fig. 5) lies mainly in the shape of the carbons, which, instead of being either pencils or circular disks as in other lamps, take the form of rectangular slabs A and B, each about 9 in. in length and 3 in. in breadth. The thickness varies in the two electrodes, that of the positive carbon B, which is placed above, being about half an inch, while that of the negative carbon A, placed below, is only about a quarter of an inch. These two slabs of carbon are in contact only along one edge. As soon as the electric current passes through them, it brings into play an electro-magnet, which lifts the positive carbon about an eighth of an inch away from the negative carbon below, which is fixed. Across the gap thus made the voltaic arc is established, the light being produced at the point of least resistance between the carbons. At the luminous focus the space between the plates gradually widens in consequence of the combustion of the carbons, thereby increasing the resistance at that spot. A time is soon reached when the current is unable to overcome this resis-

FIG. 5.—Wallace Lamp.

tance, and it then establishes itself at an adjacent point which offers less resistance. In this way the light slowly travels from end to end along the edges of the carbons; but when it reaches the extremity it makes a turn, and

slowly marches from point to point in the opposite direction. The distance between the two edges is kept constant by appropriate mechanism, and the light is thus maintained of uniform intensity. It is said that with this arrangement the light can be kept going for 100 hours without requiring a change of carbons.—Another form of lamp, invented by M. Jablochhoff, a Russian officer, in 1876, and now extensively used in Paris and London, dispenses entirely with a regulator; indeed, its extreme

FIG. 6.—
Electric
Candle.

simplicity of construction, and the manner in which it burns, have gained for it the name of the electric candle. Fig. 6 shows a single one of these candles, which consists of two pencils of carbon, each socketed in a brass tube, one of which tubes is connected with the positive and the other with the negative pole of the electric machine. Between the two cylindrical rods of carbon is interposed a layer of insulating material which keeps them electrically separate while mechanically united. At first the inventor used for this purpose a composition containing kaolin or China clay, but this was

afterward displaced by common plaster of Paris; and lately Mr. Wilde has shown that the insulating material may be wholly dispensed with, as he obtains the light by simply mounting the two rods side by side, the carbons being merely coated with hydrate of lime. A small bridge of carbon at the upper extremity of the rods serves temporarily to connect them with each other, and offers a passage for the electric current from pole to pole; and when once this passage has been established, the arc is afterward self-maintained. If the two carbons were consumed at an equal rate, the distance between them would be kept uniform; that is, they would burn down evenly together. But, as a matter of fact, the positive carbon is consumed twice as rapidly as the negative carbon. It is therefore necessary to resort to some device that will keep their extremities constantly opposite each other. This was first sought to be accomplished by making the rapidly burning carbon proportionally thick. If the sectional area of the positive carbon were twice that of the negative, it might be supposed that the ends of the two rods would be kept constantly at the same level. This was tried, but proved far from satisfactory, though it greatly improved the light. The difficulty was subsequently overcome by sending the electric current alternately through the two carbon rods, so that the pole which at one moment is positive becomes the next moment negative. The carbons are thus kept of uniform length, their upper extremities are always opposite each other, and the light becomes remarkably steady. The candles are enclosed in a globe of opaline glass, which subdues the dazzling brilliancy of the

electric arc, and converts it into a pure, soft light, though at the expense of about half the illuminating power of the naked candle. Each globe contains four candles, only one of which is lighted at a time. As each candle burns about an hour and a half, the four answer for an entire evening. As soon as one candle is burned down, the current is switched by an automatic commutator to the next, and so on. Each candle in the lantern is mounted in a brass tube securely held upright in a pair of jaws, and is connected with the electric motor by means of a cable of seven tinned copper wires which run down the hollow shaft of the lamp post and are then carried underground in earthenware drainage pipes. Fig. 7 shows the globe with its four candles, the switch, and the Gramme dynamo-electric machine from which the electric current is obtained. With reference to the motive power consumed in producing the Jablochhoff light, it is said that each separate light requires for its production one-horse power of an engine. In Paris 16 candles are served by a single Gramme machine, which thus absorbs a motive force of about 16-horse power. For this expenditure of power a very brilliant light is obtained; but much of its intensity is lost by the opal globes which are required to soften and diffuse the light. Each Jablochhoff candle

FIG. 7.—Jablochhoff Lamp.

representing one-horse power is said to have the photometric value of 700 standard candles, but the globe reduces its effective lighting power to something like 300 candles.—Inventions designed for the production of the electric light by incandescence are less numerous than those belonging to the class just described; but this mode of lighting has nevertheless received much attention, and may yet

become a rival of the electric arc. As we have seen, the light is obtained by interposing in the circuit some substance that offers increased resistance to the passage of the current. Among the materials used for this purpose are platinum, iridium, kaolin, and carbon, each having its peculiar advantages, though carbon has thus far been found most generally suitable. The earliest form of lamp designed for this mode of lighting was invented by Mr. E. A. King of London in 1845. In it a narrow strip of platinum leaf was held vertically between suitable conductors, and rendered luminous by a properly regulated current; the whole arrangement being protected by a glass globe which screened the incandescent metal from currents of air. Four years later Petrie invented a lamp in which iridium in the form of small rods was used in the place of platinum; and Mr. Edison has experimented upon an alloy of platinum and iridium. (See EDISON, THOMAS ALVA, in supplement.) In 1873 M. Lodyguine, a Russian physicist, again called attention to the subject by the invention of a lamp in which the light was produced by the incandescence of carbon. The rod of carbon through which the current passes is cut thin in one portion of its length, and, as the electric resistance is therefore greater here than elsewhere, it is this part alone that becomes incandescent. In order to avoid the waste of oxidation, the rod is enclosed in a hermetically sealed glass chamber from which the air has been exhausted; but even in a vacuum the carbon is slowly destroyed, and the pencil in Lodyguine's lamp was soon burned out. To overcome this difficulty, a lamp similar in principle but of more ingenious construction was patented in 1875 by M. Kohn of St. Petersburg, in which several carbon rods are placed side by side in such a relation that as soon as one is used up another is automatically brought into the circuit. In this way the light may be maintained without interruption for several hours; and this lamp has been used for the illumination of warehouses and other large buildings with very good results.—The Sawyer-Man lamp, which has attracted considerable attention in this country, also employs carbon for the production of the light. The apparatus is shown in fig. 8. The light-giving arrangement is separated from the lower part of the lamp by three diaphragms which cut off downward heat radiation. The copper standards below are so shaped as to present a great radiating surface, whereby the conduction of heat downward to the mechanism at the base is wholly prevented. The electric current enters from below, follows the metallic conductor to the burner, and thence downward on the other side to the return circuit. The light-producing portion is completely insulated, and also sealed at the base gas-tight. The glass vessel is charged with pure nitrogen, and the crumbling of the carbon due to sudden heating when the lamp is lighted is provided against

by the use of a switch so contrived that it is impossible to turn the current on or off abruptly.—The economy and suitability of the elec-

FIG. 8.—Sawyer-Man Lamp.

tric light for illuminating large buildings and open spaces may be considered as already amply demonstrated, and many of the recently devised systems, some of which we have briefly described, promise to accomplish, more or less successfully, that great object which has so often proved a stumbling block to the inventor—the divisibility of the light. It seems paradoxical to say that the great disadvantage of the electric light lies in its excessive brilliancy. Yet that is really the case. To temper its intensity, it is common to use shades of ground glass; but the production of an intense light to be afterward deadened is obviously a wasteful process. It is not until the strong light can be economically divided into several lights of moderate intensity that it stands a

chance of becoming the domestic light of the future. Many inventors are now at work on this problem, and it is the opinion of those

Clarke, and Saxton were long conspicuous. But perhaps the best known apparatus of this class, and one still used abroad to some extent for lighthouse purposes, is the "Alliance machine," invented by Nollet and Van Malderen of Brussels. This machine (fig. 9) has eight rows of compound horse-shoe magnets fixed symmetrically round a cast-iron frame. They are so arranged that opposite poles always succeed each other, both in each row and in each circular set. There are seven of these circular sets, with six intervening spaces. Six bronze wheels, mounted on one central axis, revolve in these intervals, the axis being driven by steam power transmitted by a pulley and belt. The speed of rotation is

FIG. 9.—Alliance Machine.

most competent to judge that success is not far distant. If an electric light of moderate power can be cheaply obtained, its advantages over gas, as at present burned, are beyond question. The electric light, for instance, does not vitiate the surrounding atmosphere as ordinary combustion does. The carbon points burn away, it is true, and thus consume oxygen and produce carbonic acid gas; but the action is insignificant compared with that which takes place during the production of the same amount of light from candles, oil, or gas. Moreover, the electric light can be produced in a closed vessel from which air is excluded; and thus the surrounding atmosphere may be kept perfectly free from contamination. Again, this light is recommended by its exceptional purity. In a gas flame the yellow rays predominate, and hence it becomes impossible by gaslight to distinguish, say, a bluish green from a greenish blue; but by the electric light colors are much more accurately discriminated.—*Electric Machines.* Little progress toward the extension of electric lighting could be made as long as the voltaic battery was the only source of electricity, the cost of generating it by this means being very great. But after Faraday's discovery of magneto-electricity in 1831, machines were constructed for the production of electricity by the rotation of an induction coil in front of the poles of a magnet. Here the mechanical force expended in the rotation of the coil, or armature, as it is called, is transformed into electricity, while in the battery it is chemical force that gives rise to the electric energy. Machines in which permanent magnets are thus used are generally known as magneto-electric machines, and among those first employed the devices of Pixii,

usually about 350 revolutions of the axis per minute. Each of the six bronze wheels carries at its circumference 16 coils, corresponding to the number of poles in each circular set. The core of each coil is a cleft tube of soft iron, this form having been found peculiarly favorable to rapid demagnetization. Each core has its magnetism reversed 16 times in each revolution, by the influence of the 16 successive pairs of poles between which it passes; and the same number of currents, in alternately opposite directions, are generated in the coils. The coils can be connected in different ways, according as great electro-motive force or small resistance is required. The positive ends are connected with the axis of the machine, which thus serves as the positive electrode; and a concentric cylinder, well insulated from it, is employed as the negative electrode. This machine is large and cumbersome, being 5 ft. 3 in. long, 4 ft. 4 in. wide, and 5 ft. high; it weighs about two tons. Its illuminating power, when driven at a speed of from 350 to 400 revolutions per minute by a steam engine, with an expenditure of somewhat over three indicated horse power, is about that of 2,500 standard sperm candles per hour. In 1857 Dr. Werner Siemens of Berlin devised a form of armature that was a great improvement on anything previ-

FIG. 10.—
Siemens
Armature.

ously used, and that has been introduced into several different machines. Instead of employing coils wound transversely round cores of iron, Siemens, after giving a bar of iron the proper shape, wound his wire longitudinally round it, and thus obtained greatly augmented effects between suitably placed magnetic poles. This style of armature is shown in fig. 10. With such an armature Mr. Wilde of Manchester constructed a machine in 1866 by which he was able to obtain currents of greatly increased intensity. Starting from a small machine, he employed its current to excite an electro-magnet of peculiar shape, between whose poles rotated a Siemens armature; from this currents were obtained vastly stronger than those generated by the smaller machine. These were conducted round a second electro-magnet of great size, between the poles of which rotated another Siemens armature of corresponding dimensions; and with currents drawn from this effects were obtained, as regards both heat and light, far surpassing anything previously known.—By the substitution of electro-magnets for ordinary or so-called permanent magnets, another great advance was made in the construction of these machines. When an electro-magnet has once been magnetized, it permanently retains a small amount of magnetism; and it was discovered almost simultaneously by Siemens, Wheatstone, and Varley, that if a coil be caused to rotate in front of an electro-magnet the residual magnetism will induce a current in the revolving armature. The current thus produced is then used to increase the magnetism of the electro-magnet by being sent through the wire that surrounds it. The strengthened magnet instantly reacts upon the coil which feeds it, producing a current of greater strength. This current again passes round the magnet, which immediately brings its increased power to bear upon the coil; and thus there is a continued action and reaction between the magnet and the armature, until ultimately very powerful currents are obtained. The machines constructed on this principle of mutual reinforcement are called dynamo-electric machines. Numerous machines of this type have since been invented both in this country and abroad, and in some of their various forms they are now generally employed to provide the electricity required for the electric light. The Gramme machine, a French invention, and the Brush machine, invented in this country, may be taken as fair examples of the class, though for effectiveness they rank considerably above the average. The descriptions appended are taken from "Appletons' Cyclopædia of Applied Mechanics," where the whole subject is very fully and clearly treated: "When a bar magnet is introduced into a coil of insulated wire, a temporary current of electricity is set up in the wire, lasting only over the period during which the bar is being introduced. On withdrawing the bar, a secondary current is caused in the wire, which flows in opposite di-

rection to the former current. If the magnet, instead of being inserted and then withdrawn, be carried entirely through the coil, it obviously in its passage comes opposite a succession of spirals or turns of wire. As it does so, it produces in each spiral a current, and these currents will all be in the same direction until the middle point or neutral axis of the magnet is reached. After that a current in reverse direction is caused. Hence, during the passage of the magnet there is produced, first a direct, and then a reversed current. If, instead of one bar magnet, two are placed end to end so that the two poles of the same name are in contact, and the coil passed over both, the phenomenon last noted will take place in the coil for each magnet separately. If in fig. 11 the coil be

FIG. 11.

made to move over these bars, we shall find that in the first quarter of the stroke, as we may term it, from A to M, we shall have a positive current; in the second quarter, from M to B, a negative current; again a negative current from B' to M'; and, finally, a positive current from M' to A'. It must also be evident that the same results will be caused if, instead of passing the coil over the magnets, the latter were made in circular form, as shown in fig. 12, and caused to pass through the coil. In order, however, to avoid the mechanical complications incident to apparatus for accomplishing this, M. Gramme devised the apparatus outlined in fig. 13. This is a permanent horse-shoe magnet, between the poles of which, N S, is placed a ring of soft iron, around which is wound a coil of insulated wire. This ring is not a permanent magnet, but when placed in the position shown becomes so by induction from the permanent magnet. The two poles S' N' will then be established in the ring. If the ring be caused to revolve, the poles will remain unaltered in space—that is to say, they will remain at N' S'; and it follows that every portion of

FIG. 12.

FIG. 13.

the ring will alternately become a north and a south pole. The consequence is, that the poles may be regarded as constantly travelling

through the iron ring at the same rate as that at which it revolves, but in an opposite direction; and the effect on the wire coiled on the ring is then precisely the same as though the magnet in fig. 13 revolved within the wire which was held at rest. It is on this translation

FIG. 14.

of polarity that the Gramme machine depends for its action; and, to go back to our starting point, its difference from other machines may be summed up in the fact that, while in the latter the magnet may be regarded as alternately entering and being withdrawn from the coil,

in the Gramme machine the magnet is to all intents constantly passing entirely through the coil. In order to collect the electricity produced, the insulating material is removed from the wire in a narrow band round the outside of the ring, and two rubbing collectors take it up in the ordinary way. The construction of the ring is shown in fig. 14. It is composed of a group of soft-iron wires, A, over which the enveloping wire B is put on in separate insulated coils. The radius pieces R are insulated from each other by ribbons of silk or India rubber. The end of the wire terminating one coil and the beginning of the wire of the next succeeding coil are each attached to one radius piece by loops and notches in the way shown. The tails of the radius bars are all grouped together round the central axis, and they are rubbed against by suitable collectors which take up the electricity. The standard machine used for illuminating workshops and factories is represented in figs. 15 and 16, and consists of two vertical frames of cast iron, united by four bars of soft iron, BBBB, which serve as cores for the electro-magnets CCCC. The axis is of steel, and revolves on long bearings, which can be effectively lubricated—a point of importance, as the speed is high, ranging from 700 to 1,350 revolutions per minute. The central ring, instead of being covered with a single wire attached by equal portions to a common

FIG. 15.

FIG. 16.

collector, is covered with two wires, wound on side by side and united with two collectors. The poles of the electro-magnets H H are much developed, embracing seven eighths of the circumference of the ring. Four wipers (*balais*) J J pick up the electricity. The electro-magnets are placed in the current, and the machine depends for the power of starting upon the small residual magnetism which remains permanently in them." This machine produces a current in only one direction, like the voltaic battery. Subsequently M. Gramme so modified it as to produce alternating currents, and this is the

form now used to supply the electricity for the Jablochkoff light. "The Brush machine (fig. 17) presents two marked differences from other machines, the first of which consists in the peculiar method adopted for winding the armature. The latter is composed of a ring or endless band of iron, but, instead of having a uniform cross section, like that of the Gramme machine, is provided with grooves or depressions whose direction is at right angles to its magnetic axis or length. These grooves, which may be of any suitable number, according to the uses for which the machine is designed, are

wound full of insulated copper wire. The advantage of winding the wire in grooves or depressions in the armature is twofold. First, the projecting portions of the armature between the sections of wire may be made to revolve very close to the poles of the magnets from which the magnetic force is derived. By this means the inductive force of the magnets is utilized to a much greater extent than is possible in the case of annular armatures as ordi-

possess a sufficient electro-motive force. This is imparted to it by multiplying the thin wires forming the convolutions of the rotating armature. Each additional convolution, like each additional cell in a voltaic battery, adds its electro-motive force to that of all the others; and, though it also adds its resistance, thereby diminishing the quantity of current contributed by each convolution, the current as a whole becomes endowed with the power of leaping

across the successive spaces necessary for the production of a series of lights in its course. The current is, as it were, rendered at once thinner and more piercing by the simultaneous addition of internal resistance and electro-motive power. The machines which produce only a single light, on the other hand, have a small internal resistance associated with a small electro-motive force. In such machines the wire in the rotating armature is comparative-

FIG. 17.—Brush Machine.

narily used, which are entirely covered with wire, and cannot therefore be brought very near the magnets. Second, owing to the exposure of a very considerable portion of the armature to the atmosphere, the heat, which is always developed by the rapidly succeeding magnetizations and demagnetizations of armatures in motion, is rapidly dissipated by radiation and convection. In the case of armatures entirely covered with wire, the escape of the heat is very slow, so that they must run at a comparatively low rate of speed, with corresponding effect, in order to prevent injurious heating. The second difference lies in the manner of connecting the armature coils to the commutator (a mechanical arrangement for gathering up the currents and causing them to flow in one direction), this being such that only the particular coils which contribute to the production of the current are in circuit at once. During the time they are passing through the neutral points in the magnetic field, they are cut out one after the other, and thus, while idle, do not tend to weaken the effects of the machine by affording a path to divert the current generated in the active sections from its proper channel." Whether a dynamo-electric machine can sustain one light or many depends upon the character of the current which it furnishes, and this in turn is determined by the manner of its construction. If the current is required to leap over say five intervals, and thus produce five lights in succession, it must

ly short and thick, copper ribbon instead of wire being commonly employed. They deliver a large quantity of electricity of low tension. Hence, though competent when their power is converged upon a single interval to produce one splendid light, their currents are unable to force a passage when the number of intervals is increased. Thus by augmenting the convolutions of the machines we lose quantity and gain electro-motive force, while by lessening the number of the convolutions we lose electro-motive force and gain quantity. If the object is to obtain a single light of great brilliancy, machines of low resistance and large quantity must be employed. If, on the other hand, it is desired to obtain in the same circuit several lights of moderate intensity, machines of high internal resistance and of correspondingly high electro-motive power must be used.—Another mode of producing the electric light is that devised by Messrs. Thompson and Houston, in which a succession of sparks is made to yield a continuous light. A pair of carbon pencils are mounted vertically, but, while the positive carbon is fixed, the negative carbon is capable of vibration. At first the two pencils are in close contact, and the current passes, of course, through them; but the movable rod by its motion breaks contact, and a spark immediately appears. Before the impression made by this spark upon the retina has faded away, the oscillating carbon springs back, whereby contact is momentarily renewed, and as momentarily

broken; another spark then appears, and, as these sparks succeed each other with great rapidity, they give rise to a continuous sensation of light. An electric light may thus be obtained with a motor much too feeble to produce the light in its ordinary form.—Still another method, which, however, promises to be of little economic importance, is that in which the electric discharge is sent through a gas or vapor in a rarefied condition, when luminous effects of great beauty are produced. The phenomena are best seen in Geissler tubes—so named after an artist of Bonn who originally devised them. These are hermetically sealed glass tubes enclosing various gases in a highly attenuated state, through which the sparks from an induction coil can be passed by means of platinum electrodes fused into the glass. On the passage of the current a soft and delicately tinted light streams through the tube from pole to pole. Although the electric light in these tubes is too feeble to be employed for ordinary purposes of illumination, it has certain special applications that give it some practical value. Thus, it has been used to a limited extent by medical men in examining the condition of any cavity of the body into which it is possible to introduce a properly shaped tube. Its use has also been suggested in coal mines where fiery seams are being worked; and for this purpose an ingenious lamp has been constructed by MM. Dumas and Benoit. It has also been proposed to use Geissler tubes in gunpowder factories, and as a means of submarine illumination.—See George B. Prescott's "The Speaking Telephone, Electric Light, and other recent Electrical Inventions" (New York, 1878), and M. Fontaine's treatise on "Electric Lighting."

ELEVATED RAILROAD, an iron viaduct on which rails are laid for the transportation of passengers by steam above the surface of the streets in a city. Owing to the narrowness of the island on which the city of New York is built, most of those residing or employed in it are subjected to the inconvenience of living at considerable distances from their places of work or business. For many years inventors have occupied their minds with devising means to shorten the time of transit between the upper and lower ends of the island. The horse railroads were welcome in New York, but they afforded only a temporary and partial remedy. When with the growth of the city the business portion encroached on the living quarter above 23d street, when a numerous population established their homes on the lands about and above Central park, and when the horse cars, imperfect and dilatory as was their service, after occupying every available avenue, were found inadequate for the traffic which pressed upon them, in the morning and evening hours especially, and became more irregular and subject to stoppages and delays with the increase in the street traffic, the question of rapid transit became more important and urgent. For a succession of years before the

construction of the elevated railroads many diverse schemes for the quick and economical conveyance of passengers were devised, patented, and described in the press to obtain popular approval; and on the basis of these stock companies were organized, and various applications for franchises made to the legislature. Some exceedingly ingenious engineering devices were proposed. A tubular tunnel, 8 ft. in diameter, through which cylindrical cars nearly of the same diameter should be driven by pneumatic propulsion, was demonstrated to be quite practicable, working with complete success in a section which the inventor had constructed under Broadway. The most original of the projects was that of an endless movable platform, travelling with a constant speed of 10 m. an hour up one side of the street and down the other, crossing the street in curves at the termini, being kept in constant motion by friction rollers actuated by shafting, operating through hollow iron columns, and driven by stationary engines underground placed at a distance of one mile apart. The moving causeway was to be elevated above the street on iron pillars. At short distances were to be stations where passengers could be transferred to and from the travelling sidewalk by the aid of wheeled carriages. Passengers, by adding their own walking speed to that of the moving floor, could advance at the rate of 14 miles an hour. This ingenious scheme was proposed by Alfred Speer of New Jersey. The results of the system of metropolitan transit adopted in London, with its known conveniences and drawbacks, caused the scheme of underground railways to be looked upon with various degrees of favor. The late Cornelius Vanderbilt long entertained a project of removing the terminus of the Harlem and Hudson River railroads to the lower part of the city by means of a sunken approach. The gigantic scheme of creating a new roadway 30 ft. below the present level of Broadway, a complete street with sidewalks and stores, whose centre should be occupied by passenger and freight railroads, was among the devices for rapid transit suggested. According to this (the arcade) plan, Broadway would consist of two streets, one above the other, the carriageway and sidewalks at the present level being restored in a completely paved deck supported by cylindrical pillars through which the drainage should pass. A charter was granted by the legislature on the application of the late William M. Tweed for a viaduct railway, to be built by the aid of a subsidy from the city of \$4,000,000, dependent on the condition that a capital of one million should be raised by private subscription.—In 1866 a practical move in the direction of rapid transit was made by the construction of the Greenwich street elevated railroad; a track was laid through Greenwich street and Ninth avenue, between Battery place and the Hudson River railroad depot in 30th street on a framework supported by a single row of iron pillars,

over which cars were to be drawn by an endless chain worked by stationary engines. The fate of this enterprise augured ill for the viaduct system. In 1871 the property was sold under foreclosure. Dr. Rufus H. Gilbert, whose attention had been directed to the problem of rapid transit by his experience as a physician of the excessive mortality in overcrowded tenement houses, had long occupied himself with this question. He devised seven different plans, and in 1872 obtained a charter at Albany for an overhead tubular pneumatic railway, the legislature having refused to grant the right of way for an underground passage. When the new company which took the control of the west side line adapted it more to the needs of the public by extending it to Central park and establishing intermediate stations, replacing the traction chain by dummy engines, it met with a measure of success which marked the plan of the elevated trestle railroad as the method of rapid transit which would certainly be adopted. However superior in theory other schemes might be, capital, with its frequent experience of the sinking of millions in novel projects, would be sure to gravitate toward the plan which had withstood a practical test. Dr. Gilbert favored at first an arched structure, but finally accepted the lattice-girder supports. Two energetic companies, backed by an abundance of capital, accomplished together the task of supplying New York with the desiderated rapid transit by girdling the island with elevated tracks. The "New York Elevated Railroad Company," the successor to the "West Side Elevated Railroad Company," was organized Jan. 3, 1872. The "Gilbert Elevated Railroad Company" was incorporated by an act of the legislature passed June 17, 1872. It received its name from its originator, Rufus H. Gilbert, and changed it in 1878, after Dr. Gilbert was superseded in the management, to that of the "Metropolitan Elevated Railroad Company." Powerful interests were leagued together to oppose the construction of the elevated railroads from the start. The horse-car companies fought against them with every weapon, as dreaded competitors and intruders upon their vested privileges; and the house-owners and store-keepers along the proposed routes, persuaded that the elevated roads would destroy the value of their property and ruin their trade, contested the improvement with stubborn resolution. The five commissioners appointed by the mayor, July 1, 1875, under legislative authority (see RAILROAD, vol. xiv., p. 184), pronounced the projected roads conducive to public interest; and three commissioners, appointed Dec. 1 of the same year, on the application of the New York elevated railroad company, decided that the portion of their plan relating to the construction of the east side road would afford sufficient benefit to the public to outweigh the objections of property-owners. —In February, 1876, the Gilbert company began the construction of their road; but after

erecting a small section in South Fifth avenue and Amity street, they were obliged to suspend operations. The contest over the right of way was hardly begun. This company received the brunt of the litigious opposition to elevated railroads at every step of its progress. The decision rendered by the court of appeals at Albany, Sept. 18, 1877, Justice Earl presiding, affirmed the constitutionality of the rapid transit acts, and finally cleared away all the legal obstacles. In October, 1877, the work on the Gilbert road was begun in earnest, and vigorously pushed to the completion of the west side division. By the end of April, 1878, the five miles of trestle work from Trinity church to Central park was erected; and on the 4th of June the road was opened. It has a double track running from Morris street to 59th street, a distance of 4.83 m. The gauge of the track, which is laid with 60-lb. rails, is 4 ft. 8½ in. The Metropolitan railroad is a more ponderous and elaborate structure than the other overhead road. The tracks are supported by two columns instead of one, and overhang the middle of the thoroughfare. The track below Canal street rests upon lattice girders, which connect the pillars longitudinally and transversely; above, it rests upon floor beams supported by the side trusses, which in turn are supported by the columns. The structure, which was built in different sections by three contractors, is warranted to bear a running load of 1,500 lbs. to the lineal foot. A solid foundation was secured for each pillar, in some instances by digging and blasting to a depth of 25 ft.; sometimes it was requisite to drive down piles to obtain a solid bed for the foundation stones. The base on which each column rests consists of a pyramid of brick masonry, laid in hydraulic cement, resting on two flat bluestones 5 in. or more thick and 6 ft. square, which are bedded in 6 in. of hydraulic mortar. A hole was excavated 6 to 12 ft. deep and 8 ft. square, on the bottom of which, after the foundation had been made solid, the base was set—first the 6 in. of concrete, then the foundation stones, and then the truncated pyramid of masonry, 4 ft. square at the top, and reaching as high as the surface of the street. Through four holes drilled in the foundation stones and upward through the column of masonry pass four upright anchor bolts, firmly fastened underneath, which, emerging at the top, hold firmly in place the cast-iron bed plate in which the columns are set. This iron casting, which the projecting rods hold down to the base by means of screw bolts, is protected from rust by a covering of cement; in the centre is a socket into which the iron pillar was lowered by the aid of a portable derrick. The bed plate, or shoe, is 3 ft. 2 in. square at the bottom, 21 in. square at the top, and 15 in. high; it weighs 1,200 lbs. The anchor bolts are 2 in. in diameter. The pillars are bolted to the bed plates by eight bolts 1½ in. in diameter, and the joint is protected by brick and cement. The square columns are composed of

two 12-inch wrought-iron channel bars and two 12-inch wrought-iron plates, riveted together. The hollow space in the centre is filled with concrete. Below Grand street the columns are hexagonal. The longitudinal girders are pin-connected trusses, usually 6 ft. 2 in. deep, the pins, 3 in. in diameter, being $5\frac{1}{2}$ ft. apart from centre to centre and bolted at each end. The top chord is formed by two channel bars 8 in. deep, united by a plate 12 in. wide. There are considerable variations in the character and dimensions of the transverse girders, and in the distances which they span. In the deck structure south of Canal street they are riveted trusses of open lattice work, the longitudinal girders resting on the cross girders inside the pillars. In Amity street they are of plate, and support the longitudinal trusses about 4 ft. inside the columns. In South Fifth

avenue they are of plate 3 ft. 6 in. deep, and span the whole street, the columns being set in the curbs 40 ft. apart. In Sixth avenue the posts are placed at some distance from the curbstones and 22 ft. apart; the cross girders are formed of panels at the ends and lattice work in the centre. The parts were made to fit together exactly. They were lifted into place by powerful derricks and steam cranes, and quickly and readily riveted to one another. The rails are laid on cross ties of yellow pine 8 ft. long and 6 by 6 in. in cross section, placed 24 in. apart from centre to centre, and resting on rolled iron beams running lengthwise, 8 by 4 in. On each side of the

rails are timber guard rails fastened to the cross ties, designed to prevent trains from being precipitated into the street in the case of derailment. There are four double curves where the railroad turns the street corners. The engines are capable of a speed of 40 miles an hour. The standard pattern introduced in 1880 weighs about 19 tons, and has a load upon the driving wheels of 6,000 to 6,500 lbs. They are furnished with spark-arresters and a smoke-consuming apparatus. The passenger cars are 37 ft. 10 in. long and 8 ft. 9 in. wide, and have seats for 48 persons each. They are well lighted, and are fitted up with bright-colored woods and painted decorations. The benches, with their backs to the sides of the car, except a few transverse seats in the centre, are composed of single seats with arms between. The stations are light, ornamental structures, consisting of small

houses whose walls are of corrugated iron with roofs of tin, on platforms, which, with their supports and the stairways by which they are approached from the street, have a frame of wrought iron. They were made after an original modern Gothic design by J. F. Cropsey, the landscape painter. The platforms are, on the average, 20 ft. high, 11 ft. wide, and 130 ft. long. During the 10 months in which the road had been in operation up to the end of March, 1879, the gross earnings amounted to \$978,834, and the expenditures to \$486,783, making a net income of \$492,050. The capital stock on March 31, 1879, amounted to \$3,155,000, and the funded debt to \$7,800,000. The cost of construction and equipment had amounted to \$10,300,000.—The "New York Elevated Railroad Company" had expended up to the beginning of 1878 \$2,843,588. The completion of

Section of Metropolitan Road in West Broadway.

the road in that year brought the cost of construction up to \$8,493,170. At the end of March, 1879, the company had issued stock to the total amount of \$5,000,000, and had a funded debt of \$7,000,000. Cyrus W. Field was chosen president of the road in May, 1877. The east side division, from Whitehall street, at the Battery, to 61st street, 5 m. in length, was opened to traffic in 1878. The road was built with a double track throughout. A siding runs from Third avenue to the Grand Central depot in 42d street, and another from Third avenue through East 34th street to the Hunter's Point ferry. An extension from Chatham square to City Hall place was opened early in 1880 as the lower section of the Third avenue line, the section from the former point to the Battery being transferred to the Second avenue line of the Metropolitan road. An

additional track was erected also on the old Ninth avenue road, which was extended to 83d street; and the old track on Greenwich street was replaced by the more solid structure of the later road. The reports of the road for the year ending Sept. 30, 1878, state the number of passengers carried during the year as 4,916,322. The total earnings were \$429,988, and the operating expenses \$250,727, leaving a balance, representing the net earnings, of \$179,260. On the completion of the Third avenue division, it drew an enormous amount

of traffic. During the six months ending March 31, 1879, there were 13,630,657 passengers carried over the road; the gross receipts for this period were \$1,038,449, of which half was estimated to be net profit over running expenses.—The structure of the New York elevated railroad differs materially from the form adopted on the other road, the viaduct being composed of a trestle work supported by single rows of columns, instead of by double rows with cross girders. The roadway passes over the posts, causing them to bear the whole

Elevated Road in Third Avenue.

strain directly. They are, however, braced together by cross girders in places where they are not separated by the entire width of the street, or where the streets are narrow, thus obtaining in a measure the additional stability afforded by the transverse trusses of the Sixth avenue structure. In Front and Pearl streets the structure is quite similar to that in the West Broadway portion of the Metropolitan line, the posts, which are set in the curbs, being connected laterally by lattice girders. From Franklin square through the Bowery to the beginning of Third avenue the posts are

placed in the curbs, and generally have no lateral connections or supports. In Third avenue they are removed 17 ft. 9 in. from the curbs toward the centre of the street, being placed on either side of the street-car tracks, 22 ft. apart; here they are connected transversely by light elliptic-arch girders formed by perforated plates. The roadway is elevated in most parts of the latter section about 17 ft. above the street level; in some places it is double this height; the lowest height allowed is 15 ft. above the street. The columns are here 15 in. square at the bottom; in the Bowery

they are 15 by 18 in. They are formed of two rolled channel beams, 15 in. wide, which are curved outward above to a sufficient width to support the longitudinal girders. Where the track passes over cross girders, as it does for a short distance in its lower course, the channel beams are straight. The two iron beams are joined together by lateral braces, consisting of bars, $3\frac{1}{2}$ in. by $\frac{5}{8}$ in., riveted to their flanges. The beams rest in sockets in a cast-iron bed plate, 3 ft. 4 in. square at the base and weighing a ton, and are secured to a base consisting of a pier of brick masonry by 2-inch anchor bolts. The columns uphold continuous girders of open lattice work, 33 in. deep. The average length of the spans is 43 ft. 4 in. The chords of the girders are formed of angle bars riveted together. The trestle is so proportioned that the strain of tension and compression shall not exceed 8,000 lbs. to the square inch, the shearing strain 6,000 lbs. to the square inch, and the maximum deflection of the span $\frac{1}{1500}$ of its length. The track is 4 ft. $8\frac{1}{2}$ in. wide. The Bessemer rails weigh 50 lbs. per yard. The cross ties of yellow pine are 7 ft. long, 6 by 5 in. in section, and stand 10 in. apart. Timber guards are placed on each side of each rail. Considerable difficulty was met with in making the curves at the street corners in the narrow down-town streets. In a case where one street had a breadth of 30 and the other of 40 ft., the curve of 90° was made by carrying a long girder diagonally across close to the inner corner, and meeting it with a cross girder brought perpendicularly across from the outer corner; the track was carried almost to the outer edge of both streets to obtain a sufficiently wide sweep at the corner. The single posts are not subjected to any trying lateral strain; but the longitudinal strain occasioned by the momentum of the train when the brakes are applied, which would have to be borne by only two or three of the columns, owing to the spaces which it was necessary to leave between the ends of the girders to allow for contraction and expansion, required a special device for securing longitudinal stability and distributing this strain over a greater number of posts. The structure was made rigid by the aid of the guard timbers, which were bolted through the cross ties to the top chord of the girders.—The west side division of the Metropolitan elevated railroad had been in operation two years before the extension to Harlem river and down the east side was completed. The east side division is intended more for through traffic. Starting from the terminus at Morris street, below the rear of Trinity church, the Metropolitan road runs through New Church street, Church street, Murray street, and College place, into West Broadway. It has a straight course through this street and its continuation, South Fifth avenue, as far as Amity street. Here two bends bring it into Sixth avenue, which it follows up to the terminus at 59th street and Central park. This portion

was completed in 1878. The route, with the Harlem and east side extensions, is to embrace the complete circuit of the island. The continuation leaves Sixth avenue at 53d street, crosses over to Ninth avenue, follows that up to 110th street, and then crosses back to Eighth avenue, occupying that till it reaches River street. Through the latter it is to pass over to the other side of the island, striking the east side division, which ascends Second avenue, at Harlem river. The road passes down Second avenue to 23d street, then over to First avenue, and down through Allen and Division streets, New Bowery, and Pearl street, to the Battery. The lower course is the joint property of both companies. On March 1, 1880, this division was opened to traffic as far as 65th street, and a few months later up to the Harlem river.—On May 29, 1879, all the elevated railroads in the city were brought under one management, the New York and Metropolitan companies leasing their property to the "Manhattan Company."—The extension of the New York road on the west side has been merged in the Metropolitan above 59th street. The new structure in the extreme upper part of the city attains dimensions far exceeding those of the earlier constructed viaducts. In the section running through 110th street, from Ninth to Eighth avenue, at the corner of Ninth avenue the road is carried on lofty columns at a height of 63 ft. above the massive iron shoes in which they are inserted, which rest on piers of solid masonry rising 30 ft. above the original level of the land, to which height the avenue itself has been filled up. The towers of masonry rest on a foundation obtained by driving piles 40 ft. into the ground below. From the double curve at 110th street, the road follows a bee line up to Harlem river, and the height of the pillars gradually decreases to the usual level above the ground. The structure at the high level is a piece of bold and original engineering, not lacking in beauty, in which the posts are connected by double cross girders and ties. The appearance of the high viaduct, which has a length of 4,000 ft. and an average height above the pavement of 45 ft., is exceedingly slight and perilous. The total height of the structure and foundations in its loftiest part is 95 ft. The foundations, 30 to 40 ft. deep in this section, cost \$200,000 a mile. If the grades had followed the streets, the maximum grade of the road would have been 170 ft. to the mile; by raising the elevation of the viaduct the grade is reduced to a maximum of 75 ft. to the mile. The construction of the east side line was begun in the early part of 1879. For a great part of the time 6,000 laborers were employed on the works. Unusual difficulties were encountered in the construction of the foundation piers. For a distance of four miles the route passed through a continuous network of gas, water, and sewer pipes. For a pier at 108th street it was necessary to drive 82 piles

and use 130 cubic yards of concrete, and bricks in proportion, as well as a bed plate of excessive size. The quantity of iron used in this division was 28,000 tons, and in the west side extension to Harlem 44,200 tons.—The regular time of the trip on the east side roads is 42 minutes from the Battery to Harlem, $8\frac{1}{2}$ m., including stoppages. Trains of three or four cars are run at intervals of 2 to 5 minutes. The time of the Sixth avenue line is 24 minutes from Rector street to 58th street, about 5 m. The time to 155th street, the last station, is 45 minutes. Trains are run to 58th street at intervals of 2 to 4 minutes, according to the hour, and to 155th street at intervals of 6 minutes.—The total length of road completed in both railroads on July 17, 1880, was 32 m. Of this, $18\frac{1}{10}$ m. belonged to the New York elevated railroad, $16\frac{2}{10}$ m. to the Metropolitan, and $2\frac{1}{10}$ m. were joint property. The length of the Second avenue line was $8\frac{3}{10}$ m.; of the Third avenue, $7\frac{1}{10}$ m.; of the Sixth avenue, $10\frac{3}{10}$ m.; of the Ninth avenue, $5\frac{1}{10}$ m.; and of the branches of the Second and Third avenue lines to Hunter's Point ferry, and of the Third avenue to the Grand Central depot, $\frac{2}{10}$ m. The number of stations on the Second avenue line was 22; on the Third avenue, 24; on the Sixth avenue, 25; and on the Ninth avenue, 16. The rolling stock comprised about 280 locomotives and 500 cars on both roads.—The elevated railroad, which, with the Brooklyn bridge, promises to supply to the inhabitants of New York the long-needed opportunity to fix their dwellings outside the overcrowded island and yet have a quick and easy access to the scenes of business activity, and follow their daily occupations in the heart of the town, was one of the schemes of rapid transit which were least approved by engineers, was least in favor with the general public, and was sure to encounter the keenest and strongest opposition. Yet, because it was first in the field and was the most economical plan, it was adopted by the practical capitalists who alone are able to carry through a needed improvement by private means, and who usually have power and popular and official support enough to overcome opposition to any undertaking in which they engage, when it promises to supply a public need. The elevated railroad has far outgrown the slight and temporary form in which it first appeared. The development has been rapid, and this form has been accepted as the final method of bringing New York into ready communication with its suburbs. It has grown in popularity with the extension of the roads. When it was first opened, there were universal complaints of the noise, the droppings, and the gloom of the elevated roads. Physicians declared that they would even affect seriously the health, the hearing, and the minds of citizens. The people of New York awakened only gradually to the superior advantages of this mode of rapid transit; but now it is usually preferred to the underground

system used in London.—The line of an elevated railroad in Brooklyn, N. Y., extends from Fulton ferry to East New York, an entire length of $6\frac{1}{2}$ miles. The superstructure, constructed of wrought iron, is calculated to bear a maximum strain of 50,000 lbs. to the square inch. In portions of the route the columns are in the middle of the street, and have arms which spread apart; these are attached to transverse girders crossing to the opposite columns. In the section which passes through Park avenue the columns are in the sidewalks, and the beams do not diverge at the top, but a bracket fastened to the inner one supports the transverse girder, which the longitudinal girders intersect some distance within the columns, as in a portion of the Metropolitan road. The longitudinal girders are of a uniform pattern throughout, and differ from the trusses of the New York lines in being of the double-intersection lattice type. The superstructure contains more iron than the New York roads, and is adapted for a running load one third greater. The columns are of the same pattern as in the New York elevated road, except that they do not rest in sockets in the bed plate, but the lower portion of the perpendicular pillars, to which the other portion is riveted, is cast in the same piece with the bed plate. The base differs essentially from the kind used in the New York lines, consisting of a solid truncated pyramid of granite, instead of brick and cement. The granite block is 4 ft. square at the bottom, 5 ft. high, and 2 ft. square at the top, this being of the same dimensions as the iron base of the column which rests upon it. The base of the column is anchored to the stone base by 4 $1\frac{1}{2}$ -inch bolts, which pass through holes drilled in the granite column and are bolted at its foot. The holes in which the foundation is laid are 6 ft. square. The bottom is filled with a bed of hydraulic cement $2\frac{1}{2}$ ft. deep, upon which the stone base rests. Cement is afterward filled in around the sides of the stone column to within two feet of the surface. In some parts of the line the tops of the stone columns are sunk to the level of the ground, but most of them project about $2\frac{1}{2}$ ft. above the surface.

ENGELMANN, George, an American botanist, born in Frankfort-on-the-Main, Feb. 2, 1809. After completing his academical course, and studying medicine and natural science in the universities of Heidelberg and Berlin, he emigrated to the United States in 1832. He remained some time in Belleville, Ill., and in 1835 established himself as a physician in St. Louis. In 1836 he founded there *Das Westland*, a German periodical, which contained a series of interesting articles upon life and manners in the United States. He gave special attention to botany, obtaining a wide recognition for his services in this science; and he has published papers on various subjects connected with it, particularly the *cactacea*, the American *conifera*, the *cuscutacea*, *euphorbiacea*, *juncacea*,

and other interesting classes of plants. His treatises on parts of the botany of California have been peculiarly valuable.

ENGLISH, William Henry, an American statesman, born at Lexington, Ind., Aug. 27, 1822. He was educated at the common schools and at Hanover college, and studied law. He took an active part as a democrat in the political campaign of 1840, and under President Tyler became the postmaster of his native village. In 1843 he was chosen clerk of the state house of representatives, and he held a clerkship in the treasury department at Washington in 1845-'9. He was secretary of the state constitutional convention in 1850, and was elected the next year to the legislature, and became speaker of the house. Beginning in 1852, he was for four consecutive terms elected to congress. In this body he was chairman of the post office committee, and one of the Smithsonian regents; but he came especially into public notice in connection with the debate on the Kansas-Nebraska bill. As a member of the committee on territories, he made a minority report against the bill and in favor of "popular sovereignty." He opposed the admission of Kansas under the Lecompton constitution,

and, as a member of the conference committee, drew up the compromise measure known as the English bill, which became the law and referred the Lecompton constitution back to the people of Kansas. Failing in his efforts to prevent the rupture in the democratic party in 1860, Mr. English declined a renomination to congress and retired from politics. He was a war democrat, and was offered the colonelcy of a volunteer regiment by Gov. Morton, but declined it. Such of his time as had not been given to public duties he had heretofore devoted to agricultural interests; but he now removed to Indianapolis, and established there in 1863 the "First National Bank" of the city, which was the first of the national banks to issue its currency. Having acquired a large fortune, he retired from the presidency of the bank and from active business in 1877. During these years he had not taken an active part in political matters, in which perhaps his well known hard-money views would have stood in his way during the financial distress following the summer of 1873. The national democratic convention of 1880, at Cincinnati, nominated him for the vice presidency by acclamation; but the election resulted in his defeat.
